Motivating Political Connections

Abstract

Why are political connections valuable to firms? To address this question, we use large language models to assemble a new database estimating the motives behind every donation made by public firms to candidates for the U.S. House of Representatives from 2000 to 2022. We find that most donations stem from firms purchasing access and influence to politicians who sit on committees with jurisdictional oversight of the firm, rather than politicians who serve on broad committees or share geography with the firm. We then link these motives to the value of firms' political connections. Exploiting the 2016 election surprise, we find that firms gained 3.4 basis points in abnormal stock returns for each Republican winner with jurisdictional oversight of the focal firm, and nothing for the rest.

Keywords: Campaign finance, Corporate political donations, Committee jurisdiction, Congress, Abnormal returns, Large language models

JEL classifications: C81, D22, D72, G38

1 Introduction

The Federal Election Commission records every dollar a corporate political action committee gives to a federal candidate, yet records nothing about why it was given. Over twelve election cycles from 2000 to 2022, the corporate PACs of 1,322 Compustat firms sent $895 million to 2,869 U.S. House candidates in 285,072 separate transactions, each public to the dollar and the day. However, none of them states a reason. The central object in the economics of corporate political activity—what the firm was trying to accomplish—is the one thing the data do not contain.

Why a firm gives money is the primitive behind almost everything else one might want to know about corporate money in politics. A donation made to reach the committee that writes a firm's own regulation is a different economic object from one made to a member who represents the district where it employs people, or from a bet on a newcomer who may hold a seat one day; the three carry different mechanisms and different expected payoffs, and any statement about what giving is worth to shareholders necessarily averages across them. The best-known puzzle in the field is itself a question about purpose: Ansolabehere et al. (2003) ask why firms spend so little if contributions buy policy, and a question about what is being bought will not be settled by looking harder at what follows.

Lacking a measure, the literature infers motive from coincidences between donor and recipient: a shared district, a committee seat the researcher deems relevant, a shared partisan lean. Each records an opportunity rather than a reason, and the committee proxy—the most used of the three—fires on 90.9% of the donations studied here, because almost every sitting member holds a seat. Its failure is conflation rather than noise. Consider two donations that every existing dataset records identically: a pharmaceutical firm and an electric utility each fund the same member of the House Judiciary Committee. For the drug maker, Judiciary writes Hatch-Waxman and the Controlled Substances Act, statutes about its products. For the utility,

Judiciary offers antitrust and bankruptcy law, which reach every firm in the economy alike. One donation buys jurisdiction over the donor's own business; the other buys, at most, general access. Both carry the same committee dummy, and no proxy built from a roster can tell them apart.

Firms buy jurisdiction and not access. A committee with jurisdiction over the donor's own industry raises the probability that the firm funds that candidate by 3.6 percentage points on a base rate of 5.8%—an increase of roughly three-fifths—while a committee whose jurisdiction covers the donor only through economy-wide laws such as antitrust and bankruptcy adds nothing (−0.22 percentage points, indistinguishable from zero). Both estimates hold the firm and the candidate fixed within the cycle, so they reflect the match between the donor's industry and the candidate's committees rather than anything about either side alone. The purchase is a choice of candidate rather than a sum of money: conditional on giving at all, the same two kinds of seat move the amount by 14.1% and −1.2%.

Knowing what a donation was for makes it possible to ask what it was worth, and we put that question to the one night in the sample when the value of a party's connections moved discontinuously. On November 9, 2016—the morning after unified Republican government arrived against 70 to 90 percent odds—donor firms were repriced by the motive composition of their political connections. A Republican winner the firm had a measurable business reason to fund is worth 3.4 basis points of abnormal market value ($t = 3.2$) within six-digit industry; a Republican winner it funded without one is worth 0.6 basis points, and Democratic winners nothing. The average firm holds twenty-three connections of the first kind, so the estimate implies a value gain of 0.79% overnight. Political connections are worth something, then, and what they are worth runs through the reason the relationship was formed: the connections a firm had a business reason to build gained, and the rest did not move at all.

We recover the motives with a large language model, and the design determines what the measure can claim. Which committees govern which industries is written in the Rules of the

House and in the statutes themselves, and it has never been tabulated against an industry classification. We build that table: nineteen committees against seventy-six GICS industries, 1,444 cells, each judged once and in isolation on whether the committee's remit reaches that industry through a statute written about it, and every credited cell naming the instrument. The 285,072 donations inherit those judgments by mechanical lookup, and the model never sees a donation.

Confining the model to that one question is what makes the measure reproducible, and the guarantees follow from the structure rather than from trust in the model: no cell is judged twice, so identical inputs cannot receive different labels, and the question put to the model names no firm, no candidate, no date, and no election, so it cannot look ahead. Misclassification between the two committee codes drives their estimated effects toward each other, which makes the contrast the paper reports a lower bound on the true one. The whole table is published with the paper, so the measure can be audited cell by cell against the statutes it names and rebuilt by anyone with the same public sources: rerunning it produces a second small table to compare rather than a second dataset to trust.

A file of donations records only the gifts that happened, so it can say how large a gift was but never why that candidate rather than another. We therefore build the alternatives: for every firm–cycle, we construct a choice set containing every House candidate who drew corporate PAC money that cycle—4,880,936 cells, on 5.84% of which a donation occurred—with the motive variables filled in for the candidates the firm passed over, reconstructed exactly against the realized donations before use.

The six reasons are recorded as concurrent indicators rather than as a hierarchy, and counted that way, they leave a tenth of the money unexplained. Jurisdiction over the donor's own industry holds on 53.6% of donations and 54.5% of dollars; a seat on the tax and spending committees on 24.7%, committee reach common to every industry on 23.5%, a powerful recipient—a member

leading a committee or the party—on 14.2%, the district where the firm operates on 12.8%, and an alumni tie between the firm's boardroom and the candidate on 4.1%. The shares sum to well past one hundred because the reasons overlap: the mean donation carries 1.33 of the six, and more than a third carry two or more. None of the six fires on 10.5% of donations and 8.5% of dollars, and that residue is itself informative: 71.4% of it backs candidates who hold no committee seat at all, where a bet on a future member is the only thing on offer, and among donations to committee-holding incumbents—the case the access literature is about—3.3% are unexplained.

The standard proxies do not merely blur this picture; they miss it in opposite directions. The committee dummy overstates the committee motive by a factor of 1.70, and one-directionally, since jurisdiction implies a seat. The geographic proxies understate, and the state-level one fails in a way an aggregate check would pass: a home-state indicator fires on 14.5% of donations against 12.8% for a measure counting the firm's local operations, a difference of nearly two percentage points, yet agrees with that measure on only 80.1% of donations, because most qualifying operations sit outside the headquarters state. A study using both proxies gets the ratio between the two motives wrong by roughly an order of magnitude.

Committee turnover lets the paper watch the motive operate in time. The probability of giving is flat in the cycles before a candidate gains jurisdiction over a donor's industry, jumps 4.6 percentage points in the cycle the assignment takes effect, and holds for at least three cycles after; losing the jurisdiction while staying on committees changes nothing, and money leaves only when the member leaves the House. Donation relationships are formed on jurisdiction and maintained on something else—which also supplies a candidate account of the giving that jurisdiction cannot explain at a point in time. Over the twenty-two years the sample covers, the pull of jurisdiction rises while the pull of geography falls, from 1.5 to 1.7 times and from 3.4 to 2.6 times the base rate respectively, though geography remains the larger throughout. That is

the drift a professionalizing PAC operation would produce: one that reads committee rosters rather than a map of its own plants.

Two alternative interpretations would make that gain something other than the value of a connection, and the design answers both. Suppose the connection counts merely revealed a firm's partisan lean. Then the reasonless gifts—the most speculative giving in the data, largely bets on challengers who hold no seat—should be repriced most; they are repriced at zero, and adding the firm's Republican share of PAC money, the alignment measure itself, moves the premium by three-tenths of a basis point. Suppose instead the market repriced regulated industries rather than connected firms. Then the party of a firm's jurisdiction connections should not matter, since a committee governs the firm whichever party's member it funded; holding the number of those connections fixed within six-digit industry, the Republican share among them is worth 2.1% ($t = 2.5$), and 3.8% ($t = 2.9$) among firms holding three or more. The premium loads on November 9 and on no other trading day in the window, is absent in November 2012 when the outcome was expected, and is present in donations completed before Trump declared his candidacy, which no election-year giving can manufacture. What the market repriced was the political identity of a firm's connections rather than its industry or its politics. The event says what the market treats as valuable; it does not say that the donation created the value, and the paper claims the first.

The paper speaks first to the literature on money and committees in Congress. Kroszner and Stratmann (1998) explain why the institution invites interested money: standing committees with fixed jurisdictions let legislators build reputations with the interests they regulate, so contributions should track jurisdiction rather than office. Powell and Grimmer (2016) come closest to testing that prediction, using involuntary committee reassignments to show that contributions track committee membership itself, and donations are tightly linked to lobbying at the firm level (Kim et al., 2025; Tripathi et al., 2002). In lobbying, where the subject matter of the

contact is disclosed, Bertrand et al. (2014) show that what a lobbyist knows matters as much as whom the lobbyist knows. Donations have had no subject-matter side: a researcher observes who sits where, never what the seat governs for a given donor. Our mapping supplies that side, and with it the jurisdiction-against-access test, which the data settle for jurisdiction.

A second literature prices corporate political activity (Akey et al., 2026). Contributions are small relative to the stakes at issue (Ansolabehere et al., 2003), and estimates of what giving is worth to shareholders vary with the design used to recover them (Aggarwal et al., 2012; Cooper et al., 2010; Fowler et al., 2020). The connections that giving builds are another matter: close elections that shift a firm's donation-built network move its market value (Akey, 2015), firms facing more policy uncertainty invest more in political capital (Akey and Lewellen, 2017), political influence reaches into credit markets (Akey et al., 2021), connections carry measurable value across settings (Akcigit et al., 2023; Faccio, 2006; Fisman, 2001), and lobbying earns returns where the policy at stake is observable (Kang, 2016). What this literature has lacked is the left-hand side of the exchange: what the firm was trying to buy. The measure supplies it donation by donation, and Section 8 shows what the distinction buys inside a single event: the connections carrying a business rationale are repriced and the rest are not, a difference that an estimate averaging across motives cannot display.

Finally, we contribute to the use of large language models in empirical economics. Existing applications put the model to work observation by observation: predicting outcomes from many signals (Gu et al., 2020), mimicking a human decision (Erel et al., 2021), or measuring a construct document by document (Bertomeu et al., 2025; Hassan et al., 2019; Li et al., 2021; Nikolov et al., 2025). A newer strand recovers how economic actors decide, reading the decision out of what the actor says or seating the model in the actor's chair (Bhagwat et al., 2026; Bybee, 2023; Fedyk et al., 2025; Filippas et al., 2023; Jha et al., 2024; Lopez-Lira and Tang, 2026). This paper shares that strand's object, the reason behind an economic choice, and inverts its method:

the model is never asked to role-play a donor, only to structure the institutional facts every donor faces. Ludwig et al. (2026) state the conditions such uses must meet—no training leakage between the model's training data and the researcher's sample for prediction, and a validation sample for measurement, absent which the errors in the output cannot be sized and the choice of model or of prompt can move estimates substantially. Our answer, for a missing variable that is documented rather than latent, is a design rather than an application: judge a small, closed, publishable mapping once, in isolation, and let every observation inherit the judgment by lookup. Determinism, immunity to look-ahead bias, and auditability at the level of the claim then hold by construction rather than by assumption. Mappings of this shape are not rare—which regulatory agencies oversee which industries, which sections of the tax code are written about which activities, which committees of a state legislature govern which markets—so the design travels past the application made of it here.

The paper has no experiment and claims none. Party steering committees make assignments, and a member seeks the committee that matters to the industries in the district and to the donors the member already has; no fixed effect removes that. The within-pair estimates bound how much of the association could run backwards, since the assignment is dated to the Congress sitting before the donation and a firm's own industry almost never moves, but they do not make the assignment random. The measure records whether a reason was available rather than whether it was operative. Furthermore, the November 2016 cross-section is a single event, and it cannot separate connections to winners from candidates funded, because 89% of the sample's Republican donations that year went to candidates who won. While the measure relies on statutory legal text by construction, mapping these jurisdictional links against self-reported lobbying disclosures remains a promising avenue for future research.

Section 2 sets out the institutional constraints that bound what a donation can be for: a capped and lumpy gift, committee jurisdictions fixed by House rules, and a donor who decides

before the election. Section 3 builds the committee-by-industry grid and states precisely what the language model is asked to judge and what it is never shown. Section 4 describes the donation sample and constructs the counterfactual choice set. Section 5 reports what corporate PAC money is for, quantifies what the standard proxies get wrong, and asks who collects the money that no measured reason explains. Section 6 estimates the margins on which these motives operate—primarily the choice of candidate rather than the size of the gift—and identifies where their influence is strongest. Section 7 follows the money as committee jurisdictions change. Section 8 exploits the November 2016 election surprise to estimate what these connections are worth to shareholders. Section 9 concludes.

2 Institutional Background

Three institutional facts govern what a corporate donation can be for, and each one narrows the set of reasons a firm could plausibly have. Corporate money reaches candidates through a vehicle whose size is capped and whose donor base is fixed by law. The candidate's capacity to act on a firm's behalf runs through committee jurisdiction, which is assigned by the parties and is sticky across Congresses. And the donor decides before the election, so anything the election determines is unavailable at the moment the money moves. This section sets out the three; Section 3 builds the measure they imply.

2.1 Corporate PACs and What the Law Allows

A corporation may not give corporate treasury money to a federal candidate, and has not been able to since 1907. What it may do is administer a separate segregated fund—a political action committee—financed by voluntary contributions from its own executives and shareholders, and give that money away in its own name. The Federal Election Campaign Act caps a PAC's gift at

$5,000 per candidate per election, so $10,000 across a contested primary and general, and the cap has never been indexed. Two consequences follow for what the data can show. The amounts are small relative to anything a regulatory decision is worth, which is the puzzle Ansolabehere et al. (2003) pose and which no subsequent work has dissolved: if contributions bought policy, firms would buy far more of it than they do. And the amounts are lumpy: 59.0% of the donations studied here sit on exactly $1,000, $2,000, $2,500 or $5,000.

The puzzle has generated two literatures that this paper sits between. One prices the donation, asking what a firm's political spending is worth to its shareholders, and finds returns that are positive but modest and hard to attribute (Aggarwal et al., 2012; Cooper et al., 2010), or that narrow sharply once the comparison is made within close elections (Fowler et al., 2020)—even though the political networks that giving builds do move firm value when close elections shift them (Akey, 2015). The other studies the adjacent technology of lobbying, where the sums are an order of magnitude larger and the object purchased is better identified (Bombardini and Trebbi, 2020; Kang, 2016). Both take the donation as given and ask what it buys. This paper asks the prior question of what the firm was trying to do, on the ground that a return cannot be attributed to a motive that has not been measured.

The lumpiness matters for where a motive can be looked for. If a firm's reason for giving showed up in how much it gave, the reason would have to move a variable that takes four values on three-fifths of the sample and is bounded above by statute. The choice of *whom* to fund carries no such constraint: a firm faces several hundred candidates each cycle and funds a few dozen. Section 6 finds the motives almost entirely on that margin, which is what the institutional setting predicts.

2.2 House Committees and Jurisdiction

A member of the House affects an industry through the committees on which the member sits. Committees hold the power to originate, amend and bottle up legislation in their own subject areas, and those areas are set by the Rules of the House rather than negotiated deal by deal. Energy and Commerce writes the Food, Drug, and Cosmetic Act and the Clean Air Act; Financial Services writes bank regulation and securities law; Agriculture writes the farm bill and the commodity exchange statutes. A firm that wants a hearing on a rule affecting its product is asking a member of the committee that governs that rule, not a member of the House at large.

Jurisdiction is what makes a committee seat worth something to a particular firm, and committee seats are not interchangeable in this respect. Kroszner and Stratmann (1998) show why the institution takes this form: standing committees with fixed jurisdictions allow legislators to build reputations with the interests they regulate, and the repeated dealing that follows is what makes a contribution informative rather than a bribe. The prediction that money should track jurisdiction rather than office is theirs; what has been missing is a measure of jurisdiction fine enough to test it against the alternative that money tracks access. Powell and Grimmer (2016) come closest, using involuntary committee transfers to show that contributions follow members onto the committees they join.

Two facts about how seats are assigned make the resulting variation usable. Assignments are made by the party steering committees at the start of each Congress, after the election that the donation precedes, so a donor observes the seat a member currently holds rather than the one the member will hold (Kellermann and Shepsle, 2009). And assignments persist: across the 2000–2022 window, 2,927 of 7,898 candidate–cycles show any change at all in the committee portfolio, so the seat a donor observes is usually the seat that survives.

Ways and Means and Appropriations sit apart from the other committees and have to

be treated apart. Ways and Means holds taxation, tariffs, Social Security and Medicare; Appropriations holds the discretionary budget, through subcommittees whose membership the data do not record. Neither has an industry-specific remit to test a firm against, because every corporation has a tax interest and every corporation can be a claimant on federal spending. Both are also exclusive under House rules: a member assigned to either generally holds no other standing committee, which is why a member of Ways and Means looks, on every industry-specific measure, like a member with no relevant jurisdiction at all.

2.3 What the Donor Observes

The donor decides before the election, and the analysis holds itself to what the donor could have known. Committee variables are dated to the Congress sitting when the donation was made, never to the Congress seated afterwards: for the 2012 cycle, the committees are the 112th Congress's. Using the incoming Congress would require assuming that both the election outcome and the subsequent assignment were predictable in advance, and would put information realized after the donation into a variable meant to explain it. Congressional district boundaries run the other way and are taken from the incoming Congress, because a candidate runs for a seat defined by the new map and redistricting is completed and published in law before the vote. The two conventions differ because they assume different things, and the pair is the combination that assumes least.

Election outcomes are excluded outright. The sample carries no vote share, no winner and no subsequent legislation, and it is built that way at source rather than filtered afterwards. Nothing in the measure can be a function of how the race turned out, which is what allows the second half of this research program—motives predicting outcomes—to be asked without circularity.

3 Measuring the Reason for a Donation

A donation record shows a firm, a candidate, an amount and a date. It does not show the reason, and no amount of care with the record will make it. This section builds a measure of the reason from outside the record, states what the measure can and cannot establish, and explains where a language model does the work and where it is deliberately kept out.

3.1 Six Reasons a Firm Funds a Candidate

What, observable before the election, would give this firm a reason to fund this candidate? The measure answers with six facts, each recorded as its own indicator for every firm–candidate–cycle. None is ranked above another, and a donation can carry several at once—the overlaps turn out to carry evidence of their own. The six divide into four types: the candidate's committee seats, in three categories; the candidate's power in the chamber; the firm's physical presence in the district; and a personal connection between the firm's boardroom and the candidate.

- *Committee.* At least one of the candidate's sitting committees matters to the donor, in one of three ways recorded separately:
  - *Industry jurisdiction.* The committee reaches the donor's own industry through a *sectoral instrument*—a statute, program or regulatory regime whose scope is defined by what that industry makes, sells or operates.
  - *Economy-wide jurisdiction.* The committee reaches the donor's industry with identifiable force, but through a legal function that applies to firms in every sector: antitrust, bankruptcy, ordinary employment law.
  - *Tax and spending.* The candidate sits on Ways and Means or Appropriations, whose remit is every firm's taxes and the government's money rather than any industry's business.

- *Powerful politician.* The candidate holds a senior post in the sitting Congress: chair, ranking minority member, or vice-chair of a committee, or a party post—Speaker, majority or minority leader, or whip.
- *Geography.* The firm's headquarters, or an establishment employing 250 or more people, sits in the district being contested.
- *Social tie.* An executive or director of the firm and the candidate attended the same institution within five years of one another.
- *Other.* None of the six indicators holds. The label is a statement about the measure rather than the donor: some reason moved the gift, but none of the reasons recorded here.

Nothing forces exactly one of the six to hold, and the design would be worse if it did. A candidate who represents the district containing a firm's largest plant *and* chairs the committee that regulates its product is a different case from one who does only the first, and shows up as different only if both can be ticked. Earlier versions of this taxonomy instead imposed a priority ordering—each donation assigned to the single most firm-specific reason that applied—and the convention failed on three counts. The size of every category below the top of the order becomes an artifact of the tie-breaking rule rather than a fact about the data. The overlaps, which carry evidence of their own, are erased rather than recorded. And the destruction is asymmetric: any ordering a reader prefers can be recovered from unranked indicators, while the indicators cannot be recovered from an ordered assignment. The categories are therefore recorded jointly, and where a single ordering is needed for a summary display it is labeled as a reporting convention.

The line between the first two committee categories is the measure's substantive content, and it is a distinction no committee dummy can draw, because both are committee seats. The operational test is whether a firm in an unrelated industry would describe the same stake in the same words. Clean Air Act Title II certifies an engine as a product before it may be sold and

reaches only firms building engine-powered equipment, so Machinery × Energy and Commerce is industry jurisdiction. Clean Air Act facility permitting reaches every manufacturing plant in the economy, so where that is all a committee has, its reach is economy-wide. The seam runs through the statute rather than around the committee.

Nor is the category a property of the committee alone: it is a property of the industry–committee pair. Judiciary is industry jurisdiction for Pharmaceuticals, where Hatch-Waxman and the Controlled Substances Act are written for that industry alone, and economy-wide for Electric Utilities, where antitrust and bankruptcy are all there is. Even Agriculture, about as sectoral a committee as exists, reaches eight industries only through commodity-derivatives law, which touches every hedger. Appendix A3 gives a worked example at each code boundary.

The three committee categories are recorded separately precisely so that any later aggregate is a projection of published columns rather than a rebuild: a single committee indicator is the maximum over the three, and a two-way split—jurisdiction over the donor's own business against reach every firm shares—costs one line. Whether the categories should be kept apart is an empirical question, and Section 6 answers it.

Incumbency is not among the reasons, and its exclusion is a substantive choice. Nearly every candidate in the data is either an incumbent or a contestant for a seat, so a reason that fires on incumbency would explain every donation equally and therefore none of them. An earlier version of this taxonomy offered incumbency as a category; it absorbed 29.2% of a 1,000-donation trial sample and carried no internal gradation whatever, which is what a category assigned by elimination looks like. Incumbency is retained as a candidate characteristic and used as such.

3.2 How the Committee Values Are Assigned

The six values are produced two ways, and the split is the design's central discipline. Wherever a mechanical construction exists, the value is a lookup or a string match on public records, because

an inference the model does not need to make is an inference that cannot be irreproducible. The model judges only where judgment cannot be avoided: the two jurisdiction categories, which require reading statutes against industries, and the social tie, which requires recognising that two differently written biographies name the same institution. Neither judgment is made about a donation, and Section 3.4 sets out what that confinement buys.

The two jurisdiction categories are judged once, as a grid: for each of 76 industries at the GICS six-digit level and each of 19 House committees, a code recording whether that committee reaches that industry through a sectoral instrument (400 cells), reaches it only as it reaches every industry (305 cells), or does not reach it beyond what every firm in the economy faces (739 cells). Every credited cell names the instrument. The line between the second code and the third is precisely the requirement to name one and show it bites this industry particularly, because every committee touches every industry in some remote sense and that is not a reason to give anybody money. The nineteen committees are the House standing committees less Ways and Means and Appropriations, plus Permanent Select Intelligence. The two money committees are outside the grid because their remit—every firm's taxes and the government's money—gives an industry-by-industry judgment nothing to vary over: the model would return the same answer seventy-six times, so a string match on the committee list supplies the indicator instead. Both are also "exclusive" committees under House rules, whose members rarely sit elsewhere—56.7% of their candidate-cycles hold no other committee, against 17.6% of other seat-holders—so for most of their members the tax-and-spending indicator is nearly the whole committee story. Appendix A3 records why each remaining inclusion and exclusion was made.

Each donation then inherits its committee values by lookup, under one assignment rule: every committee the candidate holds is classified into exactly one of the three codes for the donor's industry, because the code is a property of the industry–committee pair. A committee holding a sectoral instrument for the industry is coded sectoral even though it also touches the

industry through the legal functions every committee shares; the economy-wide code is reserved for committees that reach the industry *only* that way, so no committee is counted twice. The row-level file stores three counts—how many of the candidate's sitting committees are sectoral for this firm's industry, how many are economy-wide, how many are neither—which sum to the number of gradeable committees the candidate holds. The binary indicators the tables report are thresholds of the counts: industry jurisdiction is a sectoral count above zero, economy-wide jurisdiction likewise. Everything else derives from the counts, so nothing can drift out of step when the grid is revised.

Panel A of Table 1 works six cases, one per row, each committee graded against the donor's own industry; together they span every value the rule can produce.

Table 1: How a candidate's committee values are assigned

Panel A. The assignment rule, case by case

	Counts			Indicators	
Committees held	sectoral	econ.-wide	no reach	*Industry jur.*	*Econ.-wide jur.*
one sectoral, one economy-wide	1	1	0	1	1
two sectoral	2	0	0	1	0
three sectoral	3	0	0	1	0
one economy-wide, two reaching nothing	0	1	2	0	1
three reaching nothing	0	0	3	0	0
no committee at all	0	0	0	0	0

Panel B. A real portfolio—Agriculture, Energy and Commerce, Judiciary—graded against four industries

	The member's committees					
Donor's industry	Agriculture	Energy & Comm.	Judiciary	Counts	*Ind. jur.*	*Econ. jur.*
Pharmaceuticals	sectoral	sectoral	sectoral	(3, 0, 0)	1	0
Machinery	sectoral	sectoral	econ.-wide	(2, 1, 0)	1	1
Banks	sectoral	econ.-wide	econ.-wide	(1, 2, 0)	1	1
Transp. Infrastructure	—	econ.-wide	econ.-wide	(0, 2, 1)	0	1

The first row is the overlap a priority ordering would have erased: both committee motives hold on the same donation. The second and third rows are the intensity the indicator cannot see: industry jurisdiction saturates at one, so candidates with two and with three sectoral committees carry the same indicator, and only the count distinguishes them—the distinction the count column of Section 6.3 identifies within a candidate-cycle. The fourth row is the wedge the paper's measurement argument turns on: a candidate holding three committees whose industry-jurisdiction indicator is zero, because none of the three is sectoral for this donor—exactly the candidate a "holds any committee" dummy misreads as relevant. And the last two rows separate opportunity from its absence: a candidate with no gradeable committee could not have

had jurisdiction, while one holding three that reach nothing had the opportunity and lacked it; the third count is what keeps those apart. Throughout, the indicator asks whether a reason exists and the count asks how much of it there is.

Because the unit of the lookup is the industry–committee cell, a candidate-cycle carries not one committee value but a vector of them—one triple per industry. A real portfolio shows how far the vector moves. Panel B of Table 1 grades a member who sits on Agriculture, Energy and Commerce and Judiciary against four donor industries, cell by cell from the grid.

The same three seats produce four different values. For a pharmaceutical donor every seat is sectoral—Agriculture licenses veterinary biologics, Energy and Commerce writes drug approval, Judiciary writes the Controlled Substances Act—and the sectoral count is three. For a bank only Agriculture is sectoral (the Farm Credit Act); Energy and Commerce and Judiciary reach banking through data-security law and the Bankruptcy Code, functions every firm faces, so the count is one. For a transportation-infrastructure donor nothing is sectoral, and the industry-jurisdiction indicator is zero although the member holds three committees. Every firm in an industry faces identical committee values for a given candidate; the committee side of the measure varies across industries within a candidate and across candidates within a firm—exactly the variation the fixed effects of Section 6 retain—while geography and the social tie vary firm by firm even inside an industry. No candidate-by-industry table is stored; the grid and the committee lists reproduce the whole crossing, and the master sample carries it implicitly.

3.3 How Geography, Power, and the Social Tie Are Measured

Three of the remaining indicators involve no model at all. Tax and spending is a string match against the candidate's sitting committee list (Stewart and Woon, 2024), and the powerful-politician indicator reads the senior-party-member codes of the same file. Geography is a lookup in a firm–cycle–district panel built for the purpose: the headquarters district comes from SEC

filing headers through a cycle-keyed ZIP crosswalk, establishments of 250 or more employees are placed point-in-polygon against the congressional map on the ballot, and the firm is tied to every district where either sits. The employment floor is a materiality rule—without it a firm's establishments span a median of 57 districts, which is not a geographic tie to anybody; with it the median is 2 (Appendix A2).

The social tie is the one value judged pair by pair, because no lookup can do it. The firm's executives and directors on the BoardEx roster in the cycle are matched to the candidate's education record, assembled from the public congress-legislators identity files and Wikidata's educated-at entries, whose date qualifiers supply the graduation years; institution names on both sides are normalised by rule (sub-schools collapse to their parent, distinguishing words are never stripped). The model's judgment is confined to verifying that two differently written entries name the same institution; the strength of the tie is then graded by arithmetic on the graduation gap, with model judgment surviving only where a corroborating fact beyond the shared campus is claimed, each such claim read by the authors. A firm without a board roster in the cycle or a candidate without an education record—only candidates who served in Congress have one, so losing challengers are missing—counts as untied, so the measured rate is a floor.

3.4 What the Language Model Is Used For, and What It Is Not

The model is used to build mappings, and it is kept away from inference wherever a mechanical construction exists. The aim is to keep dependence on the model small and open to inspection, not to deny it: a value produced by a lookup cannot vary with a model that never touched it, and the judgments the model does make are confined to two small reference objects, judged once each and never about a donation—the committee grid, and institution identity for the social tie. Every other value in the sample—geography, the money committees, the powerful-politician indicator, every count and threshold, every collapse and every table—is deterministic code over

public records, and the row-level committee values are lookups into the judged grid. A different model, a different day or a different session can therefore move the paper's numbers only by changing one of the two published objects; given both, a rerun reproduces every number exactly.

The FEC record contains a firm, a candidate, an amount and a date; the reason is missing from it and always will be. In Mullainathan (2025)'s terms, supplying it is an *estimation* problem rather than a prediction problem: the researcher has a measurement procedure that would be satisfactory if it could be scaled—read each committee's legislative remit against each industry, naming the statute each time—and the model's job is to execute it 1,444 times at a standard a referee can check. Three features make the setting favourable, each worth one sentence. The missing variable is documented in the Rules of the House and the statutes rather than latent, so the task is retrieval and structuring, not inference. The object is small and closed—nineteen committees by seventy-six industries—so the model's entire output can be printed and audited rather than trusted. And the judgment is time-invariant: whether Energy and Commerce's remit reaches pharmaceuticals is not a fact about 2012, so a model that has read about 2012 knows nothing about the answer that it should not.

The committee grid. Each of the 76 industries is dispatched to the model separately, under a prompt that is byte-identical across industries except for the industry's name: it contains the coding standard of Appendix A3, four worked contrasts that fix the sectoral–horizontal line (Clean Air Act Title II against Clean Air Act facility permitting, Hatch-Waxman against patent law in general), the list of nineteen committees, and an instruction to read nothing else—no other industry, no other agent's output, no earlier version of the grid. The model is not handed the statutes. It must name, from its knowledge of public law, the specific instrument that gives a committee its reach—"FDA drug approval and exclusivity," not "health"—and a cell is credited only when an instrument is named. Four properties follow:

- *Determinism.* No cell is judged twice and no cell sees another, so identical inputs cannot receive different labels; batch order, context length and session state have nothing to act on.
- *No look-ahead.* The prompt contains no firm, no candidate, no amount, no date and no election. Whether Energy and Commerce's remit reaches pharmaceuticals is the same fact whether or not any pharmaceutical firm ever gave anybody money, so the model's knowledge of the period has nothing to leak into.
- *Auditability.* The full grid is published. A reader who doubts the committee share can read the cell that produced it and the statute named there, and disagree with that rather than with a number.
- *Testability.* Re-judging the mapping—the same model on another day, or a different model entirely—yields a second 1,444-cell table whose disagreements can be counted and read, with the paper's numbers recomputed under both codings. Per-row classification of 285,072 donations admits no such test: its output is as large as the dataset, its labels depend on how the batches were cut, and a rerun is a second dataset to trust rather than a small table to diff.

The social tie. The second judged object is narrowed before the model sees it: the tie is same-institution attendance with graduation years within five of one another—an alumni-affiliation criterion with no judgment of closeness in it—and the model's task is confined to verifying that two differently written entries name the same institution, with the evidence enclosed in the prompt and searches disabled. The evidence side is model-free: both halves of every packet are structured records—BoardEx on the firm side, the congress-legislators files and Wikidata on the candidate side—assembled and matched by ordinary code, so any model judging a pair is shown the same evidence. The verdict side is where models can differ, and there the design confines the dependence rather than eliminates it. When two models grading identical pairs

were found to disagree, the component that varied with the judge—the confidence grade—was replaced by arithmetic (Section 3.5); the 2.6% of verdicts that rested on the model's own recall rather than the enclosed evidence is measured and reported. What remains model-dependent is the same-institution verdict itself. It is published pair by pair in a single verdict file, so a reader can inspect, re-judge or discard any pair and weigh the residual dependence directly, rather than take our word for its size.

3.5 Decisions on the Record

Measurement decisions determine what this paper's numbers mean, so the consequential ones are stated here with the problem each answers. Each was made before the estimation it affects, and the superseded alternatives are retained in the replication files rather than overwritten.

Committee information is lagged because the natural merge is contaminated. Committee assignments for the Congress elected in cycle t are made after cycle t's election, so a file that attaches cycle-2000 donations to the 107th Congress hands the donor knowledge of an outcome the donation preceded. The first build of the trial sample did exactly this, the contamination was caught by checking dates rather than assumptions, and every committee variable in the paper now describes the Congress *sitting* when the money moved. Election outcomes are excluded on the same grounds.

The information cutoff is the cycle's election date, and the exposure this admits is stated rather than hidden. The unit of analysis is a cycle aggregate—the average donating pair gives in 1.8 quarters of the cycle's eight—so no single donation date exists to cut on. An election-date cutoff admits information arriving between a donation and the election, up to twenty-two months for the earliest donors. The sample records each pair's earliest donation quarter, so a robustness cut at the donation quarter is available without rebuilding anything.

What the model knows cannot be instructed away, so the design routes around it rather than legislating

against it. A model asked about a 2012 donation has read about what followed, and a prompt ordering it into ignorance is unverifiable; this is training leakage in the sense of Ludwig et al. (2026), and a design has to defeat it rather than instruct it away. The grid confines model judgment to a question—does this statute's scope cover this industry—whose answer does not depend on any donation, cycle or candidate, which is why the row-level variable can inherit it without inheriting the model's hindsight. The one field judged per pair, the social tie, was run with searches disabled and its inputs fully enclosed in the prompt; the fraction of verdicts that nonetheless rested on the model's own recall rather than the packet—institutional renames, university mergers—was measured at 2.6%, concentrated in rejections, and is reported as the reproducibility bound rather than assumed to be zero.

The social-tie confidence grade was mechanized after it was caught varying with the judge. Two models grading identical pairs against the same rule placed 13.2% and 1.2% of them at the lowest confidence—the composition of the pairs pushed the opposite way, so the gap was the judge, not the data. The grade is now arithmetic wherever arithmetic suffices: graduation gaps of four years or more, where enrollment windows cannot overlap, are graded down by rule, and model judgment survives only where a corroborating fact outside the shared campus is claimed, each such claim read by the authors. A judgment the model does not need to make is a judgment that cannot be irreproducible, and the same principle is why the grid exists at all.

Ambiguity in the raw data is carried, not resolved by fiat. A headquarters ZIP straddling district lines maps 39% of firm–cycles to more than one district; all are kept and geography fires on a match to any of them, because choosing one would be an undocumented coin flip. Refunds and zero-dollar aggregates are retained and flagged. Missing R&D is left missing rather than set to zero, a departure from common practice that costs sample and buys honesty about what the data record.

3.6 What the Measure Can and Cannot Claim

Which committee holds jurisdiction over which industry is recorded in no official register, so the grid cannot be scored against a key—and Ludwig et al. (2026) make plain what is at stake in that absence: without a validation sample the errors in a model's output cannot be sized, and the choice of model or of prompt can move the estimates that follow. The standard the grid is held to instead is consistency: one rule applied uniformly, an instrument named wherever a cell is credited, an output small enough to inspect whole, and sensitivity that is measured rather than asserted—the grid was built three times under successively tightened standards, the diffs are retained, and Appendix A3 reports the protocol with the prediction written before the run and what the run returned. The measure is also not a relabelling of candidate quality: committee portfolios receive different values depending on who is donating, and 54.2% of candidate–cycles with more than one donor differ across their donors in the jurisdiction indicator.

Four limitations remain. The measure records whether a reason was *available*, not whether it was *operative*: a firm may employ people in a district and fund its member for another reason entirely, and the grid cannot adjudicate. External validation is planned but not yet run: lobbying disclosures name the bills a firm works and therefore the committees it believes govern it (Kim et al., 2025; Tripathi et al., 2002), and lobbying data is kept out of the grid's construction so that the test stays meaningful. A model asked about a period it has read about cannot be instructed into ignorance; confining it to a question whose answer does not depend on the period bounds the problem without eliminating it. And the grid's re-judgment (Section 3.4) is specified but has not been run, so the reproducibility documented today is the determinism downstream of the grid and the 2.6% recall bound on the per-pair field, not yet an agreement rate for the grid itself.

4 Data

4.1 Sources and Sample Construction

The sample is every donation from a Compustat firm's corporate PAC to a U.S. House candidate over the twelve election cycles from 2000 to 2022, one observation per firm–candidate–cycle: 285,072 donations from 1,322 firms to 2,869 candidates, totalling $895 million. Contribution records come from the Federal Election Commission's itemised committee filings and are aggregated to the cycle. Corporate PACs are mapped to Compustat firms in two steps: PAC sponsor names and historical Compustat firm names are standardised under a single string-cleaning algorithm and matched exactly, and every candidate match is then verified by hand, so that a PAC is never attached to a firm that merely resembles its sponsor. Candidate identity, party, district and incumbency status come from the FEC Candidate Master files and the Database on Ideology, Money in Politics, and Elections (Bonica, 2014, 2024), from which only the pre-election fields are taken. Committee assignments come from the Stewart–Woon congressional committee series (Stewart and Woon, 2024), lagged to the sitting Congress as Section 2.3 describes. Firms are restricted to the Compustat universe because the second half of this research program requires accounting data.

Geography is built rather than read off an address, because a firm's headquarters is one location and its operations are many. A firm–cycle–district panel assigns each firm to every congressional district containing its headquarters or an establishment employing 250 or more people, with establishments placed by point-in-polygon against the congressional map the cycle elected. The employment floor is a materiality rule and it does real work: without it a firm's establishments span a median of 57 districts, which is not a geographic tie to anybody, and at 250 employees the median is 2. Appendix A2 gives the construction, including the vintage rule for the boundary files and why headquarters are taken from filing headers rather than from the

establishment source.

Firm financials come from the CCM-linked Compustat annual file and enter at the firm–cycle level: for donation cycle t, the fiscal year ending in calendar year t, so each firm contributes one fiscal year per cycle. From these the sample carries a standard set of controls—size, profitability, leverage, market-to-book, cash, tangibility, investment and R&D intensity, employment, dividend status—with the underlying Compustat items retained alongside each ratio. Two properties of this construction are worth a reader's attention. A December fiscal year-end, the most common, closes seven weeks after the election, so as regressors in donation equations these are slow-moving firm controls rather than strictly pre-decision values; they are absorbed by firm × cycle fixed effects wherever those are present, and a lagged variant costs one line because the panel keeps every cycle. And missing R&D is left missing rather than zero-filled, so specifications including it run on the firms that report it.

Donations at or below zero are retained rather than cleaned away—1,582 net refunds and 2,888 exact zeros—and are flagged and dropped only where a logarithm requires it. Appendix A1 defines every variable the paper uses, with its source, under the name it carries in the replication files.

The sample so far records only the gifts that happened, and can therefore say how large a gift was but never why that candidate rather than another. Recovering the second requires the alternatives. For every firm–cycle, the choice set lays out every candidate–cycle in the same cycle, with the motive variables filled in for the candidates the firm passed over as well as those it funded: 4,880,936 firm-cycle × candidate-cycle cells, on 5.84% of which a donation occurred.

The candidate universe is the corporate PAC market rather than the ballot. A candidate enters a cycle's choice set if at least one sample firm funded them that cycle, which gives a mean of 658 candidates per cycle. Candidates no corporate PAC funded at all are excluded, on the ground that they are not alternatives any of these firms plausibly weighed; including the

several hundred such candidates per cycle would inflate every coefficient by adding cells nobody considered. This is the one modeling choice in the construction and it is stated in every table that uses the sample.

The motive variables for the passed-over cells are rebuilt from primitives—the grid, the firm–cycle–district panel and the candidate's committee list—using the code that produced them for the realized cells, and the build halts unless the reconstruction reproduces all 285,072 donated rows exactly on all four. Anything short of exact agreement would mean the two samples measure different things, and the counterfactual cells would not be comparable to the realized ones. Appendix A2 sets out the step.

4.2 Variables and Summary Statistics

Three features of the donation panel shape everything that follows, and all three are visible in Table 2. The typical gift is $2,000 against a mean of $3,140, and the distribution is concentrated on round numbers as Section 2.1 describes. Relationships are persistent: half of all donations go to a candidate the firm funded in the previous cycle, and 52.4% are followed by another gift to the same candidate two years later. And the money goes overwhelmingly to sitting members—91.9% of donations, against 5.2% to open-seat candidates and 2.9% to challengers—which is why the analysis is largely an analysis of incumbents whatever else it controls for.

An executive or director of the firm and the candidate attended the same institution within five years of one another on 4.1% of donations; the 6,622 shortlisted pairs were judged as Section 3.3 describes. A donation whose firm has no board roster in the cycle (2.4% of rows) or whose candidate has no education record (3.5%) counts as untied, so the rate is a floor. The tie is counted as the sixth motive throughout Section 5; it enters no regression, for a reason the composition itself supplies: where a tie exists it overwhelmingly accompanies industry jurisdiction rather than substituting for it.

5 What Corporate PAC Money Is For

Most corporate PAC money has a reason attached to it, and the reason is usually jurisdiction over the donor's own business. This section establishes the composition before Section 6 asks whether the reasons actually move the choice of candidate.

5.1 What Explains a Donation

Jurisdiction over the donor's own industry is the modal reason for a corporate PAC donation: it holds on 53.6% of donations and 54.5% of dollars, roughly twice any other motive. Figure 1 and Panels B and C of Table 3 report the full composition, each motive counted independently on every donation. The two committee reasons that are identical for every firm follow—a seat on Ways and Means or Appropriations on 24.7% of donations, jurisdiction common to every industry on 23.5%—then a powerful recipient on 14.2%, geography on 12.8%, and a social tie on 4.1%. Dollars tilt modestly toward powerful recipients and geography, each about two and a half points heavier in dollars than in donations, because the gifts that carry them are larger.

The motives overlap, and the overlap is structure rather than double counting: the six shares sum to 133% of donations. Panel C gives the distribution: 52.7% of donations carry exactly one motive, 30.7% carry two, 6.2% carry three or more, and the mean donation carries 1.33 of the six. These overlaps are what the retired priority ordering of Section 3.1 would have erased, and one of them—jurisdiction together with geography—is where Section 6.4 later asks whether the reasons compound.

None of the six fires on 10.5% of donations and 8.5% of dollars: 29,861 gifts, $77 million, the *Other motive* category. The name is a statement about the measure rather than the donor—some reason moved each gift, but none of the reasons measured here. The six-way accounting is doing real work in keeping that residue small: the two firm-specific reasons alone, industry jurisdiction

and geography, would leave 39.8% of donations unexplained. The reasons that close the gap are common to every donor, uninformative about *which* firm gives to a candidate and highly informative about *whether* anybody does.

The residue is concentrated where jurisdiction cannot exist. Of Other-motive donations, 71.4% go to candidates holding no committee seat at all: challengers and open-seat candidates, for whom a bet on a future seat is the only thing on offer. Among the 258,195 donations to committee-holding incumbents, only 3.3% fall in the Other-motive category. The unexplained share of corporate PAC giving is small, and it is small in a way that makes sense: it sits almost entirely on people who are not yet in Congress.

Other-motive donations also look different in the one dimension that does not enter the definition. They are far less likely to be part of a continuing relationship—19.9% follow a gift to the same candidate in the previous cycle, against 50.3% in the sample at large. That is what a speculative gift to a newcomer looks like, and it is evidence against reading the residue as a set of established relationships the measure has failed to explain.

The social tie behaves as a companion to jurisdiction rather than a rival to it. Of tied donations, 57.8% already carry industry jurisdiction and 15.5% geography; only 6.0% carry no other reason, so dropping the tie from the six would move the residue from 10.5% to 10.7%. Where a boardroom connection exists, it overwhelmingly runs to the members whose committees govern the firm anyway—evidence about what alumni ties are, and the reason the tie is counted in the composition and kept out of the regressions.

5.2 The Standard Proxies Miss in Opposite Directions

Table 4 sets the proxies used in the literature against the measures used here, and the two panels fail in opposite directions. An indicator for holding any committee seat fires on 90.9% of donations against 53.6% for jurisdiction over the donor's industry, overstating the committee

motive by a factor of 1.70. The error runs one way, since jurisdiction implies a seat, so every disagreement is a false positive: of donations to a candidate holding any committee seat, 41.0% reach one with no jurisdiction over the donor's business.

The geographic proxy understates by a similar factor and is more dangerous, because its aggregate is close to right. A headquarters-district indicator fires on 2.3% of donations against 12.8% for a measure counting operations, recovering 18% of it. A home-*state* indicator fires on 14.5%—within two percentage points of the operations measure—and agrees with it on only 80.1% of donations. The reason is visible in the disagreements: 70.9% of the donations with a qualifying presence in the district come from establishments outside the firm's headquarters state, and 74.4% of same-state donations carry no qualifying presence in the contested district at all. A researcher who checked the state proxy against an operations benchmark in the aggregate would conclude it was adequate, and would be misclassifying one donation in five.

The two errors do not cancel. A study using both proxies overstates the committee motive by 1.70 and understates the geographic motive by 5.6, so the ratio between them—which is the quantity a reader takes away from a decomposition of this kind—is wrong by roughly an order of magnitude. Text-based measures tell how much politics weighs on a firm (Hassan et al., 2019), and firms facing more political risk buy more political capital (Akey and Lewellen, 2017); which committee governs the donor is a different object, and it is the one measured here.

5.3 Where the Money Sits, by Committee and by Sector

Appendix Figure A5.1 reports, for each of the nineteen graded committees, where the corporate money its members receive comes from. The grid never observes a donation, so the alignment is a consistency check rather than a construction, and it is a demanding one. Energy and Commerce draws 95.8% of its $153 million from industries it reaches through a sectoral instrument. Armed Services draws 78.3% of $100 million, Transportation and Infrastructure 69.4% of $105 million,

Financial Services 65.1% of $131 million.

Three committees anchor the other end, and they were named in advance. Budget, Rules and Ethics carry no sectoral cell for any industry in the grid, because none of the three has an industry-specific remit to have one. The prediction on record before the grid was built was that they would return all zeros, and they do. They also receive $65 million, $23 million and $19 million respectively—money whose reason jurisdiction cannot supply, and which the composition reaches only through the tax-and-spending, leadership or Other-motive categories, depending on what else the member holds.

Sectoral composition follows the same logic without being told to. Appendix Table A4.1 orders the eleven GICS sectors by the share of their donations reaching a committee with jurisdiction over their own industry, and the ordering is recognisable: Energy at 62.5% and Communication Services at 59.0% at the top, Consumer Staples at 48.3% and Consumer Discretionary at 48.6% at the bottom. Geography runs almost exactly the other way—30.4% for Consumer Discretionary and 25.4% for Consumer Staples against 5.7% for Communication Services—which is what retail footprints and district-level employment should produce.

Firms give past the odds on both margins. A high jurisdiction share is not by itself evidence of targeting, since a firm in a heavily regulated industry would post one by giving at random; the benchmark is the share of the cycle's own choice set that carried jurisdiction over that firm. Appendix Figure A5.2 plots the two. The average firm-cycle realises a jurisdiction share 17.7 percentage points above what the choice set offered and a geography share 12.7 points above, and the gap is positive in every sector for both reasons.

5.4 Who Receives the Other-Motive Money

The same money reads differently from the recipient's side. The residue is a candidate-level fact once aggregated, and it is systematic rather than noise. Table 10 collapses the sample to the

candidate–cycle and asks what predicts corporate money and its composition. A committee portfolio reaching the whole corporate economy is worth 1.98 log points of corporate receipts and 1.21 log points of donor count; a seat on Ways and Means or Appropriations is worth 1.74 and 1.00. A committee portfolio that reaches broadly and a seat on the money committees command comparable sums.

Columns 3 to 5 are partly definitional and should be read as magnitudes rather than as tests. Reach, the money committees and the powerful-politician indicator are three of the six motives whose joint absence defines the dependent variable, so each must push the unexplained share down; what the columns add is how far. Reach and the money committees do comparable work, at −0.42 and −0.35 on a share, and the powerful-politician indicator about a third as much at −0.12. The restriction to incumbents in column 5, where the question has content, leaves the pattern intact.

Column 6 carries no such circularity and returns the least expected result in the table. Holding the number of donors fixed, a candidate whose committees reach more of the corporate economy draws a donor base that is *narrower* by sector, not wider: the coefficient is −0.48 sectors on a mean of 6.7. Broad jurisdiction does not assemble a broad coalition of donors. It assembles a large one drawn from the industries the portfolio actually governs, which is the same selection Figure A5.1 shows committee by committee, seen from the candidate's side.

6 Which Candidate a Firm Funds

6.1 Specification

The paper has no experiment and does not claim one. What the data have is a cross-classified panel: the same candidate receives from firms in many industries, and the same firm gives to

many candidates, so two sets of fixed effects can be imposed at once. Estimates take the form

$$Y_{fct} = \beta_1 J_{fct} + \beta_2 G_{fct} + \alpha_{ft} + \gamma_{ct} + \varepsilon_{fct}, \tag{1}$$

where Y_{fct} is an outcome for firm f and candidate c in cycle t, J_{fct} indicates that a sitting committee of c reaches f's industry through a sectoral instrument, G_{fct} that f has a qualifying presence in c's district, α_{ft} is a firm × cycle effect and γ_{ct} a candidate × cycle effect. Standard errors are clustered two ways, on firm and on candidate; both dimensions repeat, and clustering on either alone understates the other by roughly a factor of three.

The two fixed-effect sets do different jobs and the paper reports the full sequence rather than the final column alone. A firm × cycle effect absorbs everything about the donor in that cycle—its size, its PAC budget, its politics, its taste for giving. A candidate × cycle effect absorbs everything about the recipient—seniority, leadership, party, the safety of the seat, whether the race is contested, and membership of Ways and Means. Imposed together they leave the interaction: two firms giving to the same candidate in the same cycle differ in J because their industries differ, and one firm giving to two candidates differs in J because their committees differ. That is variation the grid supplies and no proxy can produce.

Two outcomes are estimated on two samples. On the choice set, Y indicates whether the firm funded the candidate, and Equation 1 is a linear probability model whose coefficients are read against a base rate of 5.84%. On the donations, Y is log dollars, and the sample loses the 4,470 observations at or below zero that cannot be logged. The first asks whether a reason moves the choice of candidate; the second asks whether it moves the size of the gift conditional on that choice.

What the design does not settle is that committee assignment is not random. A member seeks the committee that matters to the industries in the district and to the donors the member

already has, and no fixed effect in Equation 1 removes that. Section 7 bounds how much of the association could run backwards, by holding the firm–candidate pair fixed and using the fact that the assignment is dated before the donation. It bounds the problem; it does not eliminate it.

6.2 Motive Lives on Selection, Not on Size

Table 5 reports the two margins on the same sequence of fixed effects, and the contrast between them is the paper's central quantitative result. On the choice of candidate, jurisdiction over the donor's industry raises the probability of a donation by 3.68 percentage points against a base rate of 5.84%—an increase of roughly two-thirds—and a qualifying presence in the district raises it by 14.28 points, or roughly two and a half times the base rate. Both are estimated with firm × cycle and candidate × cycle effects and both exceed fourteen standard errors.

On the size of the gift the same two reasons are worth 14.6% and 36.5%. Those are not small numbers, but they are an order of magnitude smaller than the selection effects relative to their bases, and the institutional setting predicted as much: the amount is bounded by statute and sits on a round number three times in five, while the choice of whom to fund is unconstrained. A firm expresses its reasons by picking a candidate, and having picked, gives what it gives.

The movement across columns is itself a result and is the reason the table reports every column. Pooled with only cycle effects, jurisdiction is associated with 3.2% more money, significant at the ten percent level and economically slight. Adding firm × cycle effects leaves 2.4%, indistinguishable from zero. Adding candidate × cycle effects raises the coefficient to 14.6% and its t-statistic above ten. Raw means say the same thing about the pooled comparison: donations to candidates with jurisdiction average \$3,194 against \$3,077 for those without, a gap of 3.8%, which is the pooled estimate and not the within-candidate one.

The reason the pooled comparison hides the effect is that candidates whose committees reach many industries are systematically different candidates. Broad reach concentrates on

committees like Energy and Commerce, whose members are senior, safe and heavily funded from every direction; the pooled coefficient mixes the jurisdiction premium with whatever else makes such a member attractive. Only after the candidate is held fixed, and the comparison runs across donors from different industries funding the *same* person, does jurisdiction separate from candidate quality. That the sign of the finding depends on this is a caution for any study using a committee proxy without the cross-classified structure to condition on the recipient.

6.3 Only Own-Industry Jurisdiction Draws Money

The measure's central distinction predicts that the second committee code should carry no weight once the first is controlled, and Table 6 tests it. A committee reaching the donor's industry only as it reaches every industry is associated with a -0.22 percentage point change in the probability of a donation (standard error 0.13), a -1.2% change in the amount (0.87), and a -0.2% change in dollars under Poisson estimation over the whole choice set (2.3). Sectoral jurisdiction in the same specifications is worth +3.60 points, +14.1% and a factor of 1.88.

The contrast is not a mechanical consequence of one variable being rarer. Economy-wide reach fires on 23.5% of donations against 53.6% for sectoral jurisdiction, so the estimates are comparably precise; the economy-wide coefficient is not imprecise, it is close to zero and negative. Nor is it an artefact of comparing committee-holders with non-holders: column 4 restricts to candidates holding at least one seat, so the contrast becomes a seat with jurisdiction against a seat without, and the coefficients barely move.

This is the strongest available evidence that the grid is measuring jurisdiction rather than relabelling committee membership. Both codes describe committee seats; both are assigned by the same model under the same standard in the same isolated judgments; they differ only in whether the statute the model named is written about the donor's industry or about all industries. Firms pay for one and not the other. A committee dummy of the kind used in the

literature pools the two and returns their average, which is how a proxy overstating incidence by 1.70 can nonetheless appear to work.

Compounding the two margins, jurisdiction nearly doubles the dollars a firm sends a candidate and district presence more than triples them. Column 6 estimates this by Poisson pseudo-maximum-likelihood on dollars over the whole choice set, which admits the zeros and so combines the decision to give with the decision of how much, and puts the two factors at 1.88 and 3.30. These are the magnitudes to quote for total dollars, and they sit between the two margins as they should.

6.4 Do the Reasons Compound?

The additive specifications assume a firm with a plant in the district gains as much from jurisdiction as a distant firm, and Table 7 tests that assumption with the same variation that identifies everything else: within a candidate–cycle, donors differ in industry, in geography, and in the combination. In percentage points the reasons reinforce each other. Jurisdiction alone raises the probability of funding by 3.4 points and geography alone by 11.6; holding both adds a further 7.7 points, taking the joint effect to 22.7 points on a 5.8% base—the likeliest recipient of a firm's money is the representative of a district where it operates who also governs its industry, at roughly a 28% probability of being funded. The count version says the same thing at the margin: an additional committee with jurisdiction is worth 2.4 points to a distant firm and 8.5 to a local one.

The proportional reading tempers the multiplicative extreme. In the Poisson column the two reasons alone multiply the probability of funding by 1.8 and 3.3; if they compounded fully, holding both would multiply it by 5.8, and the estimated interaction pulls the joint ratio back to 4.5. The joint effect therefore sits between the additive and the multiplicative benchmarks: the reasons are complements in levels and partial substitutes in proportions, which is what two

channels to the same member's attention should produce.

The dollars follow the probabilities, and almost entirely through selection. Over the whole choice set, jurisdiction alone multiplies the expected dollars a firm sends a candidate by 1.9, geography alone by 3.7, and both together by 5.8 against a multiplicative benchmark of 7.2 (column 4)—the same between-benchmarks structure as the probability of giving. Once a donation is made, by contrast, the compound buys little extra size: the mean gift rises only from $3,047 with neither reason to $3,900 with both, the intensive-margin interaction is small and negative (column 5), and the cap and focal amounts of Section 2.1 leave the size margin little room to move. The compounding of total money is therefore a compounding of *whom the firm funds*, not of how much it hands over. The level-complementarity also closes a loop with Section 3.1: multi-reason donations are not ties to be broken but the likeliest donations in the data, and a priority ordering would have discarded exactly the cells where the motives do their strongest joint work.

6.5 The Premium for Power within the Committee

Power within the committee commands a premium on top of membership of it. Table 8 splits the jurisdiction seat by the candidate's role: a rank-and-file seat on a committee with jurisdiction over the donor's industry raises the probability of funding by 3.4 percentage points, chairing such a committee adds a further 5.6 points—a chaired jurisdiction seat is worth 2.7 times a rank-and-file one—and the ranking minority member commands a premium of 4.1 points. The same ordering holds on the amount: given a donation, jurisdiction is worth 13% more dollars, a chair 18% on top of that, the ranking member 15%. Geography is unmoved at 14.3 points throughout, so the roles are not absorbing some other channel.

Both terms vary across donors within a candidate–cycle exactly as the jurisdiction indicator does—chairing Energy and Commerce is a chaired jurisdiction seat for a pharmaceutical donor

and not for a bank—so the two-way fixed effects identify the premium from the same industry-committee match as everything else in this section. Two readings follow. The chair premium says firms pay most for the person who controls what the committee does to their industry, which is what buying jurisdiction should look like at a finer grain. And the near-parity of the ranking member's premium says the purchase spans the aisle: the minority's committee leader is worth almost what the chair is, consistent with firms positioning for the committee's agenda under either majority rather than for the current one alone.

6.6 More Jurisdiction, More Money

The relation is monotone in the number of committees and concave in it (Appendix Figure A5.3). One committee with jurisdiction over the donor's industry raises the probability of a donation by 3.4 percentage points, two by 4.7, three or more by 6.1; in log dollars the same steps are 13.8%, 17.8% and 20.8%. The first committee does most of the work, which is what an access story implies—a firm needs a hearing somewhere in the process, and a second seat adds less than the first.

A dose response is a weak test on its own and a useful one in combination. It would arise mechanically if the count were proxying for how many committees a candidate holds in total, but the specification also carries the count of committees reaching the donor's industry only economy-wide, and that count is worth 0.29 points against sectoral jurisdiction's 2.58. The count of committees reaching the industry not at all cannot be identified separately: within a candidate $\times$ cycle cell the total number of seats is fixed, so the three counts carry two degrees of freedom.

6.7 Small PACs Give on Geography, Large PACs on Jurisdiction

The estimates so far report an average effect, and it pools firms whose PAC programs differ by a factor of thirty in size: and Appendix Table A4.2 separates them. Because base rates range from

0.47% in the smallest quartile of PAC programs to 17.0% in the largest, the comparable quantity across rows is the coefficient divided by the base, and the table reports both.

The geographic motive belongs to the small PAC. In the smallest quartile—firms funding a median of three candidates—a qualifying presence in the district raises the probability of a donation by more than eighteen times the base rate, while jurisdiction raises it by 0.74 times. In the largest quartile, funding a median of 88 candidates, geography is worth 0.87 times the base and jurisdiction 0.59. Both reasons matter everywhere and geography's coefficient is never the smaller one; what collapses with scale is its dominance, from roughly twenty-five times jurisdiction's pull in the smallest quartile to one and a half times in the largest—the convergence a fixed cost of learning committee rosters implies.

The candidate's status splits the sample differently. Jurisdiction is worth 0.45 times the base rate for incumbents and is indistinguishable from zero for open-seat candidates, which is mechanical: a candidate who holds no seat has no jurisdiction. The challenger row is worth reading carefully. Its jurisdiction coefficient is 2.97 times the base rate and highly significant, and it rests on 653 donation rows involving eighteen candidates coded as challengers who nonetheless appear with committee assignments—former members seeking to return. The estimate is real and its subject is narrow.

7 When Jurisdiction Moves

Section 6 establishes that jurisdiction draws money; this section asks what that relationship does afterwards—when the jurisdiction that formed it moves, and across the twenty-two years the sample covers. The first question gives the sharpest answer: money arrives when a candidate gains jurisdiction over a donor's industry and does not leave when the jurisdiction goes, so corporate donation relationships are formed on jurisdiction and maintained on something else.

7.1 Money Arrives with Jurisdiction and Does Not Leave with It

Holding the firm–candidate pair fixed and letting the candidate's committee assignment change underneath it gives the sharpest result in the paper. Table 9 reports first differences between consecutive cycles for pairs observed in both,

$$\Delta Y_{fct} \;=\; \delta^{+}\, Gain_{fct} \;+\; \delta^{-}\, Lose_{fct} \;+\; \Delta\varepsilon_{fct}, \tag{2}$$

where $Gain_{fct}$ indicates that candidate c held no committee reaching firm f's industry in the previous cycle and holds one now and $Lose_{fct}$ the reverse. Differencing removes any level specific to the pair—everything fixed about the match between this donor and this candidate, including whatever drew them together in the first place—so δ^{+} and δ^{-} compare the same relationship with and without jurisdiction rather than comparing relationships to one another. When a candidate gains jurisdiction over a donor's industry—held no committee reaching it last cycle, holds one now—the probability that the firm gives rises by 4.59 percentage points and the amount by 21.9%. When the same candidate loses jurisdiction but remains on committees, the probability changes by 0.24 points (standard error 0.22) and the amount by 1.0% (1.7). Neither is distinguishable from zero.

The asymmetry is not an artefact of pooling two kinds of loss. A member can shed jurisdiction by being reassigned within the House or by leaving it, and only the first holds the relationship fixed. Separating them shows why the pooled loss coefficient is misleading: leaving all committees is associated with a 8.95 point fall in the probability of a donation and a 62.2% fall in the amount, while reassignment within the House is associated with nothing. Money leaves when the member leaves, not when the jurisdiction does.

Two facts make the comparison readable in this direction rather than the other. The committee assignment is dated to the Congress sitting *before* the donation, so the money moves after the

assignment rather than before it. And a firm's own industry almost never moves—GICS6 changes in 146 of 7,410 firm–cycles—so a within-pair switch is the candidate's committee change and not a reclassification of the donor. This bounds how much of the cross-sectional association in Section 6 could run backwards from money to assignment. It does not make the assignment random, and the paper does not claim it does.

Figure 2 traces the gain cycle by cycle. The probability of giving is flat before the change—−0.5 and −0.4 percentage points at three and two cycles prior, neither significant—jumps 4.8 points in the cycle the assignment takes effect, and stays there: 4.9, 4.9 and 5.0 points at one, two and three cycles after. On a base rate of 4.6% in the pre-period this is a doubling, and it is a level shift rather than a drift. The right panel shows the loss, restricted to members who stay on committees, and it is flat throughout the post-period. Its rising pre-period is not a placebo failure: to be at risk of losing jurisdiction a pair must first have gained it, so the run-up into the omitted cycle is the tail of the left panel.

Read together, the two panels say that corporate donation relationships are formed on jurisdiction and maintained on something else. That interpretation also supplies a candidate account of the money carrying only firm-invariant reasons, and of the Other-motive residue: some of it will be relationships whose original jurisdictional reason has since moved on, and which the measure, looking only at the current Congress, cannot see. The data here cannot separate that from a taste for maintaining contacts, and the paper does not try.

The same life cycle is visible descriptively in Figure 4, which traces each motive's incidence by how many consecutive cycles the firm has funded the candidate. The Other-motive residue is a first-gift phenomenon: it sits on 18.9% of first-cycle gifts, against 4–5% once the relationship survives a cycle, so the speculative bets on newcomers happen at formation and what survives is explained. Jurisdiction accounts for half of first gifts and peaks in the relationship's second cycle; from there the mix tilts steadily toward Ways and Means and Appropriations, from 16.4% of first

gifts to 25.4% at the fourth cycle or later. Those are the seats members reach with seniority, so a maintained relationship ages with the member's career rather than with the industry-committee match that started it—which is what the within-pair estimates imply, seen from the composition side.

7.2 The Composition Has Shifted, and the Two Motives Have Moved Apart

Composition is stable in levels and the pull of the reasons is not, which is why Figure 3 and Figure 5 answer different questions. Figure 3 reports the shares. Industry jurisdiction moves from 48.7% of donations in 2000 to 55.4% in 2022, tax and spending from 25.1% to 27.1%, geography from 9.3% to 13.4%, and the Other-motive share falls from 15.3% to 8.9%. The mean gift roughly doubles in nominal terms, which the unindexed FECA cap makes a fall in real terms.

Estimating Equation 1 cycle by cycle tells a different story about the same period. Because the unconditional probability of funding any given candidate rises from 5.4% to 6.9% over the window, a constant percentage-point effect would be a shrinking one, so Figure 5 estimates by Poisson and reports a ratio of probabilities. Jurisdiction rises from 1.5 to 1.7 times; district presence falls from 3.4 to 2.6. Corporate PAC giving has become more responsive to what a committee governs and less responsive to where a firm employs people.

The lines do not cross, and the finding is the two trends rather than a reversal. Geography remains the larger effect in every cycle: a firm is still more likely to fund a candidate because it employs people in the district than because a committee reaches its industry. What has changed is the gap between them, and the direction of the change is what a professionalising PAC operation would produce—one that reads committee rosters rather than a map of its own plants.

8 Do the Motives Price? Evidence from the 2016 Election Surprise

On November 9, 2016, the market repriced donor firms by the motive composition of their political connections. Firms whose Republican connections carry a measured motive gained; Republican connections without one were worth nothing that morning; and the same pattern holds in donations completed before Trump declared his candidacy. This section uses the one night in the sample when the value of a party's connections moved discontinuously to ask whether the taxonomy of Section 3 draws a line that prices.

8.1 Design

The event is the arrival of unified Republican government against the odds. Forecasts and prediction markets put Clinton's probability at 70 to 90 percent through election day; Trump won with a Republican House and Senate, and the repricing that followed was broad and immediate—Wagner et al. (2018) document large cross-sectional moves on taxes and trade, and Child et al. (2021) show that firms with ties to Trump gained. The design follows the event-study logic of Acemoglu et al. (2016): when political power shifts unexpectedly, the cross-section of returns reveals which firm characteristics the market prices as political.

The unit is the firm, and the regressor is the motive composition of its connections. A connection is a donation in the 2016 cycle to a House candidate who won the general election, counted by the winner's party; each donation carries its most firm-specific motive (industry jurisdiction, then geography, a social tie, tax and spending, economy-wide reach, leadership), so the counts partition into connections with a *measured* motive and connections in the *Other* category, on which none of the six fires. The specification is

$$CAR_i(-1,+1) \;=\; \beta_m\, R_i^{meas} \;+\; \beta_o\, R_i^{other} \;+\; \beta_d\, D_i \;+\; \gamma' X_i \;+\; \alpha_{g(i)} \;+\; \varepsilon_i, \tag{3}$$

where R_i^{meas} and R_i^{other} count the firm's Republican winners by motive, D_i its Democratic winners, X_i holds log market value, log assets, ROA, leverage and market-to-book, and $\alpha_{g(i)}$ is a GICS6 industry effect. The outcome is the market-model cumulative abnormal return from the Monday before the election to the Wednesday after. Counts enter raw, so coefficients are per winner funded; the Republican-winner count has a cross-sectional standard deviation of 33, almost all of it in the measured part.

8.2 The Repricing Sits on Measured-Motive Connections

An additional Republican winner is worth three basis points, and only if the firm had a measurable reason to fund him. Table 11 column 1 prices the connection count itself: 3 basis points per Republican winner ($t = 3.1$) within GICS6 industry, with Democratic winners at zero. Column 2 splits the count by motive: the measured part carries the effect (3.4 basis points, $t = 3.2$) and the Other part carries none of it (0.6 basis points, $t = 0.1$).

The magnitudes are economically meaningful without being extravagant. The average sample firm holds 23.4 measured-motive Republican connections, so the estimate implies an election-week move of 0.79 percent of market value, and the spread between a ninetieth- and a tenth-percentile firm is 2.1 percentage points. Adding the connection counts raises the cross-sectional R^2 from 0.285 to 0.301: political connections are a real component of what moved firm values that week, and a modest one beside industry, size and the rest of the cross-section.

The gain is dated to the morning after the result and is absent when the outcome is expected. Estimated one trading day at a time (Table 13), the measured-motive coefficient is zero on every day from November 3 through election day, loads on November 9—the first trading day after the result—and is gone by November 10. The same specifications in November 2012, when Obama's re-election was expected and the House stayed Republican, return nothing (Table 11, column 6). In an untabulated placebo that re-estimates column 2 on eighty pseudo-event dates through

2016–2017, the November 9 coefficient sits in the top 2.5 percent.

Donations that predate the candidacy show the same structure, more sharply. Columns 4 and 5 measure connections from the firm's 2014-cycle donations—completed before Trump declared in June 2015—counted against the November 2016 winners, with motives and controls at the 2014 cycle. The measured-motive premium survives (5 basis points, $t = 2.8$) and the Other-motive count turns negative (−14 basis points, $t = -2.4$). No donation in these counts can be a response to the campaign, so the split cannot be manufactured by election-year giving.

8.3 What the Pattern Rules Out, and What It Cannot

The first alternative is that donations reveal partisanship rather than motive, and the Other category is its placebo. Firms that fund Republicans are disproportionately firms positioned to gain from Republican policy, so any count of Republican connections could price alignment rather than access. But alignment makes a prediction about the residual: Other-motive Republican giving—largely speculative gifts to challengers holding no seat (Section 5.4)—is the most partisan-flavored giving in the data and should be repriced at least as strongly. It is repriced at zero in 2016-cycle connections and negatively in pre-announcement ones. Columns 3 and 5 add the firm's Republican share of PAC money, the alignment measure itself: it enters insignificantly and leaves the measured-motive premium at 3.1 basis points ($t = 2.8$).

The second alternative is that the regulated were repriced rather than the connected. A firm whose industry is governed by congressional committees is exactly the firm whose value swings with the policy regime, so a count of jurisdiction connections may be counting exposure to that regime. Table 12 separates the two by estimating

$$CAR_i(-1,+1) \;=\; \pi\, s_i^R \;+\; \lambda\, N_i \;+\; \gamma' X_i \;+\; \alpha_{g(i)} \;+\; \varepsilon_i, \tag{4}$$

where N_i counts the general-election winners the firm funded whose committees hold jurisdiction over its industry and s_i^R is the Republican share among them. Exposure enters through N_i and is held fixed; π compares two firms in the same six-digit industry, equally connected to the committees that govern their business, differing only in the party of the members who supply that jurisdiction. Exposure is constant along that margin by construction, so a policy shock common to an industry cannot generate a π different from zero. It is 2.1 percent ($t = 2.5$), and 3.8 percent ($t = 2.9$) among firms holding three or more jurisdiction winners (columns 2 and 3). The same contrast appears on pre-announcement connections (column 4).

Together the two tests locate what was repriced. It was not the firm's industry, which the fixed effects hold fixed, nor its partisan lean, which enters the regression directly and does nothing: it was the political identity of the firm's connections—which politicians it had funded, of which party, standing in what business relationship to the firm.

Within the measured motives, the event cannot rank. Appendix Table A4.3 splits the measured count into its six categories: at the sector level jurisdiction, tax-and-spending and geography each carry 11 to 15 basis points per winner relative to an Other-motive winner, and none is statistically separable from the others—the categories are collinear with the total and the small ones are noisy. The claim this section supports lives at the measured/Other margin, not between measured motives.

Two limits bound the interpretation. First, the winner margin is not identified: 89 percent of the sample's Republican donations in 2016 went to candidates who won, and across firms the number of Republican winners funded correlates 0.999 with the number of Republican candidates funded, so this event cannot say whether the losers' donors lost. Second, the premium sits on newer relationships—splitting the measured count by vintage, first-cycle connections carry 8 basis points ($t = 2.9$) while relationships already in place the cycle before carry a statistically flat 1 (Appendix Table A4.4)—so what was repriced is not long-established relationship capital;

the pattern is consistent with newer ties reaching the newer cohort of members whose standing rose with the outcome, and we offer it as description. The section therefore claims validation, not a return: the taxonomy, built from statutes and maps with no price data anywhere in its construction, predicts which firms the market repriced when political power moved.

9 Conclusion

Why does a firm fund a politician? For the 285,072 corporate PAC donations studied here, the answer is usually written in the statutes: firms fund the members whose committees govern their business. Jurisdiction over the donor's own industry accounts for half of corporate giving and the remaining recorded reasons for most of the rest, leaving a tenth unexplained—largely bets on candidates who hold no committee seat yet. A seat without that jurisdiction is not a substitute: committees that touch the donor only through economy-wide law attract nothing, which is why the standard committee dummy overstates the motive it means to measure by a factor of 1.7. And the relationship is built when jurisdiction arrives but not unwound when it departs, so donation ties outlive the reason for which they were formed.

Connections carry value, and the value follows the reason the relationship was formed. When unified Republican government arrived against 70-to-90-percent odds in November 2016, the firms that gained were those holding Republican connections they had a measurable business reason to build: 3.4 basis points in abnormal returns per such connection, nothing for Republican connections without one, nothing for Democratic connections, and nothing at all in the expected election of 2012. The gain survives holding the firm's partisan lean fixed and holding its six-digit industry fixed, and it is present in donations completed before the candidacy that produced the surprise existed. What the event establishes is what the market treats as valuable rather than what a donation causes: 89% of the sample's Republican donations that year went to candidates

who won, so it cannot separate connections to winners from candidates funded.

The findings change what can be asked of the returns literature. An estimated return to political spending has until now averaged over donations made to a regulator, to a neighbor, and to a prospect, as if one asset were being priced; with a motive attached to each donation, returns can be estimated within motive, where they have a meaning. Money given for jurisdiction should pay, if it pays, in regulatory and legislative outcomes for the industry; money given for geography, in decisions that touch the district. November 2016 shows that the distinction is one the market itself draws when the value of a party's connections moves overnight, which is a reason to expect the same distinction to matter in the slower outcomes a donation is actually aimed at.

The method's transferable part is the design, not the model. The scarce step was locating, inside a question about hundreds of thousands of transactions, a small closed mapping—1,444 cells, each answerable from public statutes—that could be judged once, in isolation, published whole, and inherited by every observation mechanically. Mappings of the same shape are common: which regulatory agencies oversee which industries, which sections of the tax code are written about which activities, which committees of state legislatures govern which markets. Wherever one exists, determinism, immunity to look-ahead bias, and audit at the level of the claim come from the design rather than from trust in the model.

The grid's external validation runs through lobbying disclosures, in which firms name the bills they work and therefore the committees they believe govern them; lobbying data has been kept out of the grid's construction so that the test stays meaningful. Beyond it lies the question this paper opens rather than closes. One night in November tells us the market prices a firm's connections by the reason they were formed; what remains is to follow each motive into the outcome it was aimed at—the rule, the statute, the appropriation—and ask what the money bought there.

Figure 1: **What explains a corporate PAC donation**

The left panel counts each of the six motives independently on the same 285,072 donations, weighted by count and by dollars; the shares sum to more than one hundred because motives overlap. The right panel is the distribution of how many of the six fire on a single donation, with the first bar the Other-motive residue. Table 3 reports the underlying counts and defines each category.

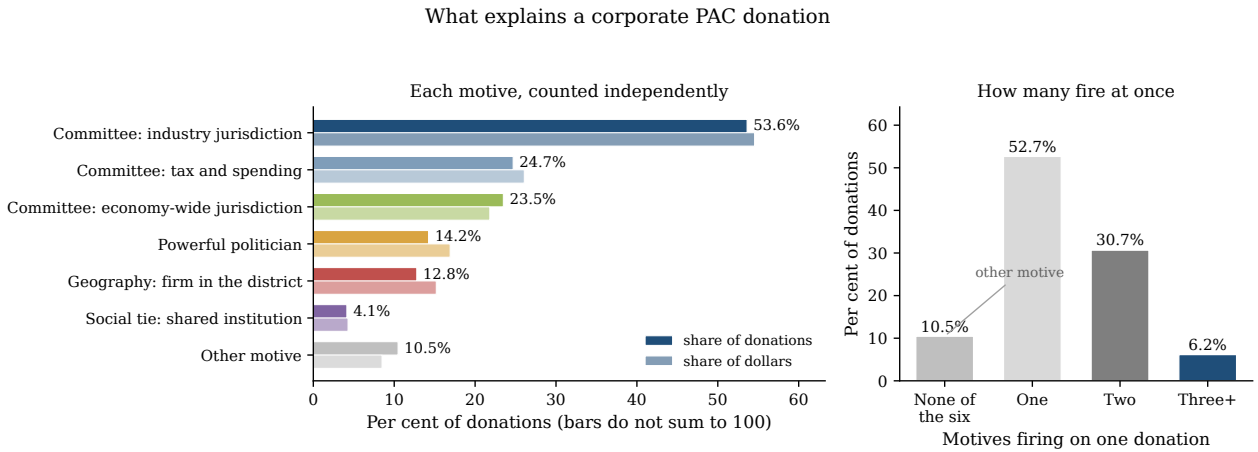

Figure 2: **The probability of giving around a change in jurisdiction**

Cycles are indexed relative to the first cycle in which the firm–candidate pair's jurisdiction status changes; the cycle before the change is omitted. The right panel keeps only members who remain on committees, which is the only version of the loss that holds the relationship fixed. Its rising pre-period is the tail of the left panel: to be at risk of losing jurisdiction a pair must first have gained it.

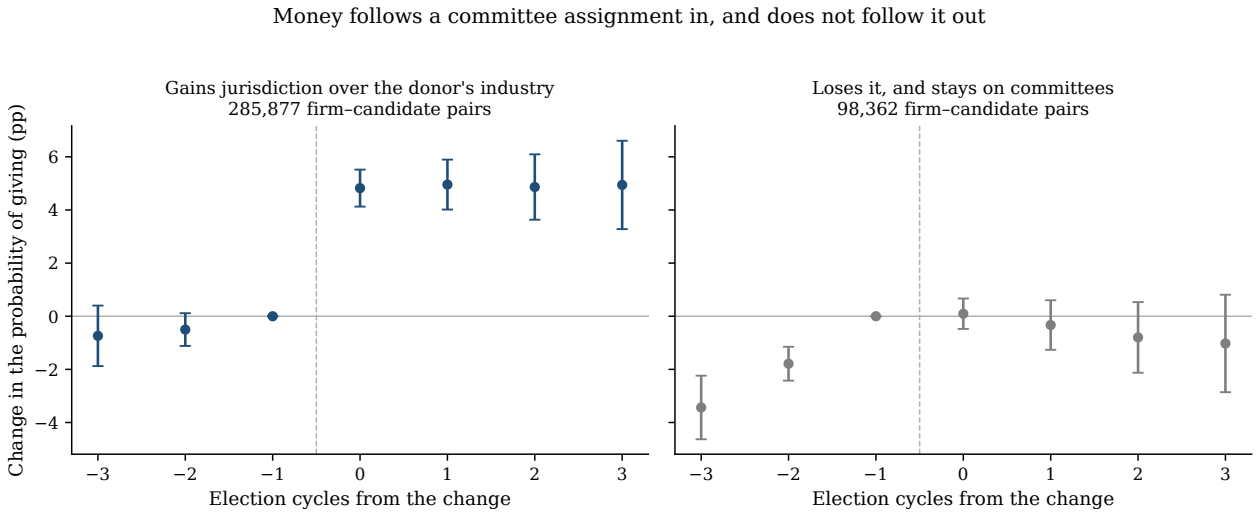

Figure 3: **Motive composition, 2000–2022**

Share of each cycle's donations on which each reason fires. The reasons are not mutually exclusive and do not sum to one hundred; Other motive is the share on which none of the six fires.

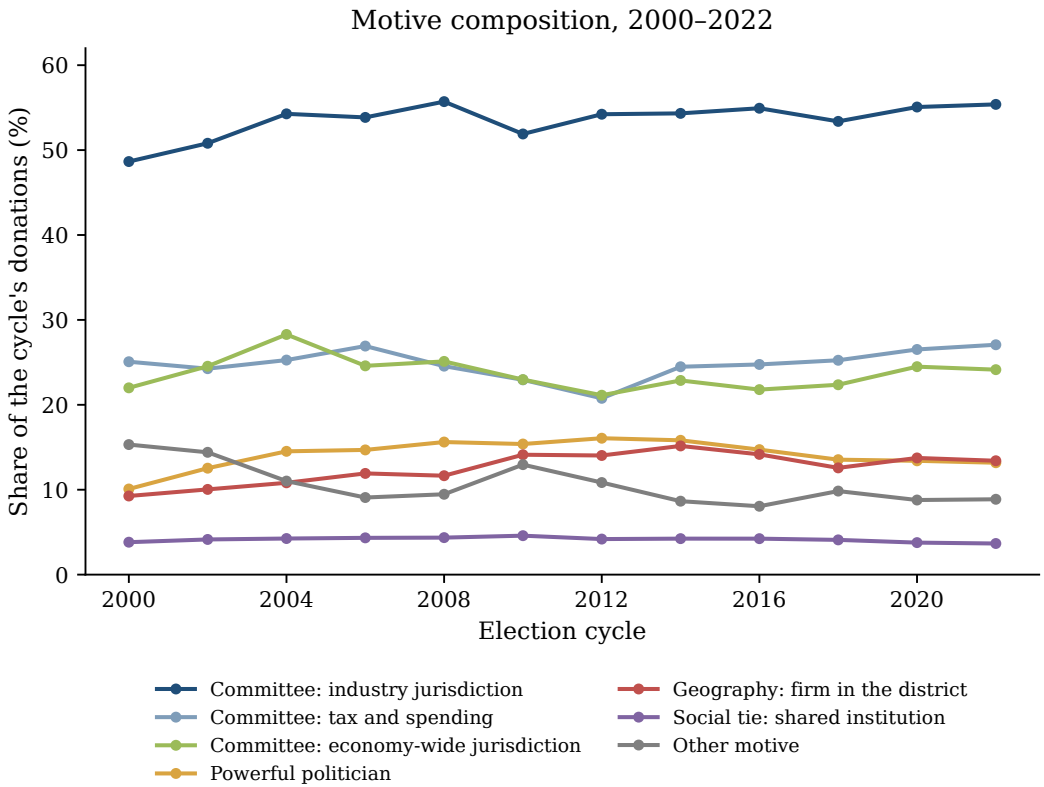

Figure 4: **What the reason is, by the age of the relationship**

Each motive's incidence among donations, split by the number of consecutive cycles the firm has funded this candidate; a lapsed and restarted relationship re-enters at one. The right panel is the Other-motive share at each relationship age, which falls steeply once a relationship survives its first cycle. The categories follow Table 3.

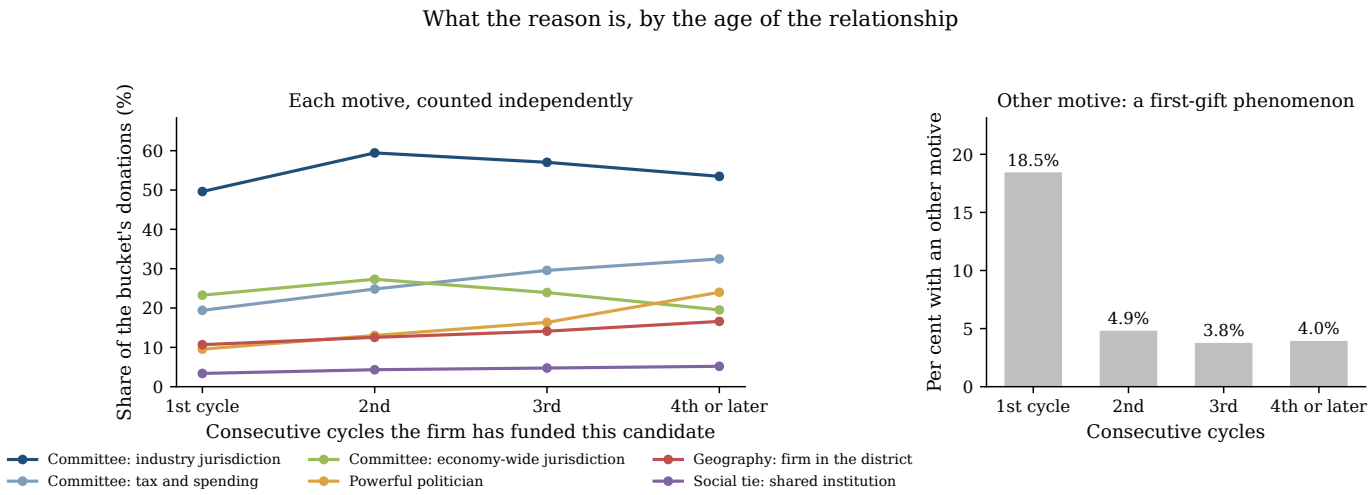

Figure 5: **The two motives over time**

Poisson estimates of the specification in Table 5 column 3, run cycle by cycle, so that each point is a ratio of probabilities rather than a difference in them. Shaded bands are 95% confidence intervals from standard errors clustered on firm and on candidate. The lines do not cross: geography remains the larger effect throughout.

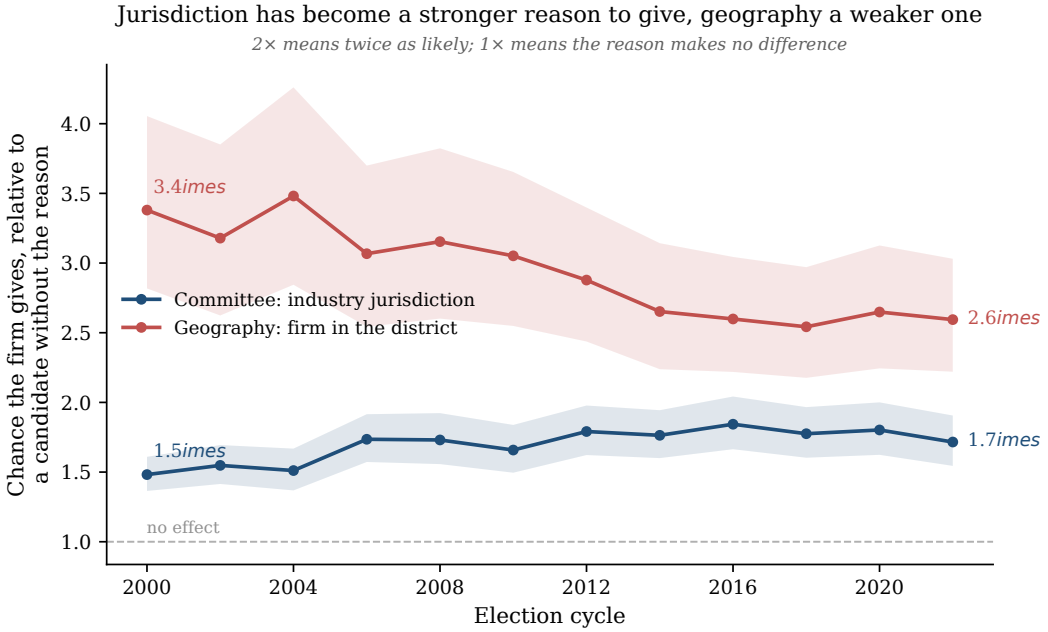

Table 2: **Summary statistics**

Panels A–D are the firm–candidate–cycle donation sample: every donation from a Compustat firm's corporate PAC to a U.S. House candidate, 2000–2022 cycles. Panel E collapses that sample to the firm–cycle and to the candidate–cycle, so a firm that funded no candidate in a cycle and a candidate who received nothing are absent by construction. Donations at or below zero are refunds and net-outs and are retained rather than dropped. Committee variables use the committees of the Congress sitting when the donation was made, not the one seated after the election. Gives to this candidate next cycle is missing for the 2022 cycle, which has no successor in the window. The shared-institution tie equals one when an executive or director on the firm's roster in that cycle and the candidate attended the same institution with graduation years within five of one another, judged per pair over the two biographies rather than looked up from a grid; a donation whose firm has no roster that cycle or whose candidate has no education record is a zero, so the rate is a floor. Firm financials are the Compustat fiscal year ending in the cycle's calendar year, at the firm–cycle level; the source items are kept alongside each ratio in the replication files, and missing R&D is left missing rather than set to zero. Dollars are nominal.

	Mean	SD	P25	Median	P75	N

Table 3: **The sample, and what explains a corporate PAC donation**

Panel A counts the sample: every donation from a Compustat firm's corporate PAC to a U.S. House candidate over the 2000–2022 election cycles, one row per firm–candidate–cycle. Panel B reports each motive independently, so a donation carrying two motives is counted in both rows and the shares sum past one hundred; Panel C reports how many of the six fire on the same donation, which is the same information organised so that it does sum to one hundred. Neither panel ranks the motives: they are unranked indicators, and a priority ordering would silently determine the size of every category below the top of the order. The three committee rows differ in whose business the committee's remit is written about. *Industry jurisdiction* means a committee reaches the donor's own GICS6 industry through a sectoral instrument – a statute, program or regulatory regime whose scope is defined by what that industry makes, sells or operates – and every credited cell of the committee × industry grid names the instrument. *Economy-wide jurisdiction* means the committee reaches the industry only through a legal function that applies to firms in every sector: antitrust, bankruptcy, ordinary employment law. *Tax and spending* is Ways and Means or Appropriations, whose remits are identical for every donor and so are supplied mechanically rather than judged. Geography means the firm's headquarters or an establishment with 250 or more employees sits in the district being contested, measured against the congressional map on the ballot. A *social tie* is an executive or director on the firm's roster and the candidate having attended the same institution within five years of one another. *Other motive* is the residue: not one of the six fires. It is not a claim that no reason exists, only that none of the reasons measured here does; 71% of it goes to candidates holding no committee seat at all. Dollars are nominal.

	Donations	% of donations	$m	% of dollars
Panel A. Sample				
Firm–candidate–cycle donations	285,072		895	
Firms (gvkey)	1,322			
Candidates	2,869			
Election cycles	12			
Firm–cycles	7,410			
Candidate–cycles	7,898			
Panel B. Each motive, counted independently				
Committee with jurisdiction over the firm's industry	152,852	53.6	488	54.5
Committee on tax or spending (Ways and Means, Appropriations)	70,413	24.7	233	26.1
Committee with jurisdiction common to every industry	66,959	23.5	195	21.8
Powerful politician (leads a committee or the party)	40,605	14.2	151	16.9
Geography: firm HQ or a 250+ job plant in the district	36,459	12.8	136	15.2
Social tie: executive and candidate share an institution	11,820	4.1	38	4.3
Other motive (none of the six measured)	29,861	10.5	76	8.5
Panel C. How many motives fire on one donation				
None of the six	29,861	10.5	76	8.5
One motive	150,190	52.7	464	51.8
Two motives	87,440	30.7	292	32.6
Three or more	17,581	6.2	63	7.1

Table 4: **The standard proxies against the measures used here**

Each row is the share of the 285,072 donations on which the indicator fires; the last column divides that share by the paper's own measure, set in bold. In Panel A the standard proxy – an indicator for sitting on a committee – overstates the committee motive by 1.70 times, and the error runs one way: jurisdiction implies a seat, so every disagreement is a false positive. Of the donations to a candidate holding any committee seat, 59% reach one with jurisdiction over the donor's own industry. In Panel B the two levels are close and the classifications are not. A home-state indicator and an operations-in-the-district measure agree on only 80% of donations, because 71% of the donations with a qualifying presence in the district come from establishments outside the firm's headquarters state, and 74% of same-state donations carry no qualifying presence in the contested district at all. A home- district indicator built from the headquarters ZIP alone recovers 0.18 of the measure.

	% of donations	Donations	Ratio
Panel A. Committee			
Sits on any committee	90.9	259,235	1.70
Sits on one of the 19 graded standing committees	72.8	207,619	1.36
Committee on tax or spending (Ways and Means, Appropriations)	24.7	70,413	0.46
Committee with jurisdiction over the firm's industry	53.6	152,852	1.00
Committee with jurisdiction common to every industry	23.5	66,959	0.44
Panel B. Geography			
Headquarters state equals the candidate's state	14.5	41,428	1.14
Geography: firm HQ or a 250+ job plant in the district	12.8	36,459	1.00
Headquarters district equals the contested district	2.3	6,569	0.18
Headquarters in the district, from the establishment panel	2.2	6,198	0.17

Table 5: **Which candidate a firm funds, and how much**

Columns 1-3 are a linear probability model on the choice set: for every firm-cycle, every U.S. House candidate who received corporate PAC money from any sample firm in that cycle, whether or not this firm gave. Columns 4-6 are the donations themselves, dropping the 4,470 rows at or below zero that cannot be logged. The candidate universe is the corporate PAC market rather than the ballot: candidates whom no corporate PAC funded are excluded, since they are not alternatives any of these firms weighed. Committee jurisdiction is an indicator that at least one of the candidate's sitting committees reaches the donor's own GICS6 industry through a sectoral instrument, looked up from a committee x industry grid; geography is an indicator that the firm's headquarters or an establishment with 250 or more employees sits in the district being contested. Both use the Congress sitting when the donation was made and the congressional map on the ballot. With firm x cycle and candidate x cycle fixed effects together, the estimate is identified only by the match between the donor's industry and the candidate's committees: two firms giving to the same candidate in the same cycle differ in jurisdiction because their industries differ. Standard errors, clustered two ways on firm and on candidate, are in parentheses. Statistical significance: * p<0.10, ** p<0.05, *** p<0.01.

Table 6: **Industry jurisdiction against jurisdiction common to every industry**

Columns 1-4 are a linear probability model on the choice set; column 5 is log dollars among the donations that occurred; column 6 is Poisson pseudo-maximum-likelihood on dollars over the whole choice set, which combines the two margins and admits the zeros, with net refunds set to zero. Economy-wide jurisdiction is a committee whose remit touches the donor's industry only through a legal function that applies to firms in every sector – antitrust, bankruptcy, ordinary employment law – as against a sectoral instrument written about what the industry makes, sells or operates. The two are recorded separately in the grid and can both be true of the same candidate. Column 3 also enters the number of the candidate's committees reaching the donor's industry not at all; it is absorbed and drops out, because the candidate's total committee count is fixed within a candidate x cycle cell, so the three counts carry two degrees of freedom rather than three. All columns carry firm x cycle and candidate x cycle fixed effects. Standard errors, clustered two ways on firm and on candidate, are in parentheses. Statistical significance: * p<0.10, ** p<0.05, *** p<0.01.

Table 7: **Do the reasons compound?**

Column 1 is a linear probability model on the choice set and column 2 is Poisson pseudo-maximum-likelihood on the same outcome. Column 3 is Poisson on dollars over the whole choice set with refunds set to zero, so it combines the two margins; cells in fixed-effect groups with no positive dollars are dropped by the estimator, which is why its observation count is lower. Column 4 is log dollars among the donations that occurred. The interaction is identified within a candidate-cycle: donors differ in industry, in geographic overlap, and in the combination. Columns 2 and 3 are the informative scale: under no interaction Poisson rate ratios multiply, so the interaction term asks whether holding both reasons multiplies to more or less than the product of holding each alone. All columns carry firm x cycle and candidate x cycle fixed effects. Standard errors, clustered two ways on firm and on candidate, are in parentheses. Statistical significance: * p<0.10, ** p<0.05, *** p<0.01.

Table 8: **The premium for power within the committee**

All columns carry firm x cycle and candidate x cycle fixed effects with standard errors clustered two ways on firm and candidate. The baseline without the role indicators is Table 5, column 3. Chairs such a committee means the candidate chairs at least one committee holding sectoral jurisdiction over the donor's own industry, so the coefficient is the premium over holding such a seat as a rank-and-file member; the ranking-minority row is the analogous premium for leading the committee's minority side. Both vary across donors within a candidate-cycle exactly as the jurisdiction indicator does: chairing Energy and Commerce is a chaired jurisdiction seat for a pharmaceutical donor and not for a bank. Committee roles come from the same sitting-Congress assignment file as the committee lists. Statistical significance: * p<0.10, ** p<0.05, *** p<0.01.

Table 9: **Money arrives with industry jurisdiction and does not leave with it**

Columns 1 and 4 hold the firm-candidate pair fixed and estimate in levels; the rest are first differences between consecutive election cycles for pairs observed in both. Gains industry jurisdiction means the candidate held no committee reaching the donor's own industry in the previous cycle and holds one now; loses it is the reverse. The loss is split by whether the member still holds any committee seat afterwards: reassignment inside the House against leaving it. Committee assignments are those of the Congress sitting before the donation, so the money moves after the assignment. This bounds reverse causation; it does not make the assignment random. Standard errors, clustered two ways on firm and on candidate, are in parentheses. Statistical significance: * p<0.10, ** p<0.05, *** p<0.01.

Table 10: **Who receives the money in the Other-motive category**

The unit is the candidate-cycle, restricted to the 7,898 House candidate-cycles that received corporate PAC money from at least one sample firm. Other motive means none of the six measured motives fires: no committee with sectoral jurisdiction over the donor's industry, no seat on Ways and Means or Appropriations, no committee whose jurisdiction is common to every industry, no senior post leading a committee or the party, no headquarters or 250-plus-job establishment in the district, and no documented alumni tie. It is not a claim that no reason exists, only that none of the reasons measured here fires. Columns 3 and 5 weight donations equally; column 4 weights them by dollars. Reach is the share of the grid's 76 GICS6 industries over which the candidate's sitting committees hold sectoral jurisdiction. Standard errors, clustered on candidate, are in parentheses. Statistical significance: * p<0.10, ** p<0.05, *** p<0.01.

Table 11: **The November 2016 surprise: the motive composition of a firm's connections predicts its repricing**

One observation per firm with House PAC donations in the connection cycle and an election-week abnormal return. The dependent variable in every column is the firm's market-model CAR(−1, +1) around the named election; November 2016 delivered unified Republican government against 70–90 percent odds, and November 2012 was the expected outcome (the placebo). Connections are the firm's donations in the named cycle to candidates who won the general election, counted by the winner's party; 2014-cycle connections were completed before Trump declared his candidacy in June 2015 and are counted against the November 2016 winners. Each donation carries its most firm-specific motive (industry jurisdiction, geography, social tie, tax and spending, economy-wide reach, leadership, in that order); *measured motive* means any of the six fires and *Other motive* means none does. Counts are raw, so coefficients are per winner funded; the R-winner count has a cross-sectional standard deviation of 33, its measured-motive part 31 and its Other-motive part 4. The Republican share of PAC money is the firm's dollar share to Republican candidates in the cycle. Controls: log market value, log assets, ROA, leverage and market-to-book at the connection cycle's fiscal year. Heteroskedasticity-robust standard errors in parentheses. * p<0.10, ** p<0.05, *** p<0.01.

Table 12: **The party of the jurisdiction connection**

As Table 11; the dependent variable is the market-model CAR(−1, +1) around November 8, 2016. A firm's jurisdiction connections are the general-election winners it funded whose committees hold jurisdiction over its industry, split by the winner's party; the R share among them holds the firm's exposure to committee jurisdiction fixed and varies only the party of the connection. If the repricing reflected the exposure of governed industries to the incoming policy regime, R and D jurisdiction connections would load alike; they do not. Columns 2–3 restrict to firms with at least one (three) jurisdiction winner(s), where the R share is defined. Heteroskedasticity-robust standard errors in parentheses. * p<0.10, ** p<0.05, *** p<0.01.

	2016-cycle connections			2014-cycle connections

Appendix

A1 Variable Definitions

Variable names below are the column names in the four analysis files, so a table in the paper, a coefficient in a regression and a column in the replication data carry the same label. Cycle t runs from the January after the previous general election to the general election in November of year t. *Sitting Congress* means the Congress in session when the donation was made, which is the Congress elected at $t-2$; *incoming map* means the district boundaries contested at t. Section 2.3 explains why the two conventions differ.

Variable	Definition and source
Panel A. Identifiers and units	
`gvkey`	Compustat firm identifier.
`cand_id`	FEC candidate identifier, as carried by DIME (Bonica, 2024).
`cycle`	Election cycle, even years 2000–2022.
`firm_cycle`	Group identifier for `gvkey` × `cycle`; 7,410 groups. Absorbed as a fixed effect.
`cand_cycle`	Group identifier for `cand_id` × `cycle`; 7,898 groups. Absorbed as a fixed effect.
`pair`	Group identifier for `gvkey` × `cand_id`; 130,171 groups in the donation sample.
`hist_gics2`, `hist_gics4`, `hist_gics6`	Historical GICS sector, industry group and sub-industry codes for the firm in the donation year. The grid is defined at GICS6, of which 76 appear in the sample.
Panel B. Donation variables	
`amt`	Total corporate PAC dollars given by the firm to the candidate in the cycle, summed over itemised FEC contributions. Nominal. Negative values are net refunds and are retained.
`ln_don`	log(max(`amt`, 1)). Defined on the 280,602 donations above zero.
`refund`	= 1 if `amt` < 0.
`gave`	Choice set only. = 1 if the firm gave to this candidate in this cycle; 0 for a candidate in the same cycle's choice set that the firm passed over.
`ln_don_0`	Choice set only. log(max(`amt`, 1)) with `amt` = 0 on the passed-over cells.
`gvkey_cand_don_qtr_count`	Number of calendar quarters of the cycle in which the firm gave to this candidate.
`earliest_gvkey_cand_d_cycle_qtr`	The first of the cycle's eight quarters in which the firm gave to this candidate.
`gvkey_cand_don_nth_cycle`	The number of consecutive cycles, ending at t, in which the firm has given to this candidate.
`repeat_donor`	= 1 if the firm gave to this candidate in cycle $t-2$.
`gave_next`	= 1 if the firm gives to this candidate in cycle $t+2$. Missing for 2022, which has no successor in the window.

continued on the next page

Variable	Definition and source
Panel C. Motive variables	
cmte_sector_juris	= 1 if n_cmte_sectoral > 0: at least one committee of the sitting Congress on which the candidate serves reaches the firm's GICS6 industry through a sectoral instrument. From the committee × industry grid, Appendix A3.
cmte_horiz_reach	= 1 if n_cmte_horizontal > 0: at least one such committee reaches the industry only through a legal function applying to firms in every sector.
n_cmte_sectoral	Count of the candidate's sitting committees with grid code reach = 2 for the firm's industry.
n_cmte_horizontal	Count with reach = 1.
n_cmte_noreach	Count with reach = 0. Not separately identified within a candidate × cycle cell, where the total number of seats is fixed.
cmte_wm_approp	= 1 if the candidate sits on Ways and Means or Appropriations in the sitting Congress. String match on cmte_l1; equals max(cmte_wm, cmte_approp).
geography	= 1 if the firm's headquarters, or an establishment employing 250 or more people, lies in the district contested by the candidate at t. Equals max(in_hq, in_estab_250) from the firm–cycle–district panel, Appendix A2.
in_hq	= 1 if the firm's headquarters district, from the SEC filing header through a cycle-keyed ZIP crosswalk, is the contested district.
in_estab_250, in_estab_500	= 1 if the firm operates an establishment of at least 250 (500) employees in the contested district, placed by point-in-polygon against the incoming map. The 500-employee variant is retained for sensitivity and is not used in the reported results.
n_motives	Count of the six motive indicators firing on the donation: cmte_sector_juris, cmte_wm_approp, cmte_horiz_reach, cand_power_l1, geography, social_tie.
no_motive	= 1 if n_motives = 0. Displayed throughout as *Other motive*.
ladder, no_reason	The retired priority ordering and its residual, kept as audit columns only: the most firm-specific reason that applies, coded 1 industry jurisdiction through 5 powerful politician, 6 residual. Used in no reported exhibit; Table 3 counts the six motives independently instead.
sect_chair, sect_ranking	= 1 if the candidate chairs (is ranking minority member of) at least one sitting committee with sectoral jurisdiction over the firm's industry; n_sect_chair and n_sect_ranking are the counts. Roles are parsed from the same sitting-Congress committee list as the assignments.
firm_specific	= 1 if cmte_sector_juris = 1 or geography = 1.
social_tie	= 1 if an executive or director on the firm's BoardEx roster in the cycle and the candidate attended the same institution with graduation years within five of one another, judged per pair rather than looked up from a grid. Candidate education comes from the congress-legislators identity files and Wikidata's educated-at entries with their year qualifiers; executive education from BoardEx; both sides normalised by rule before matching. A donation whose firm has no roster in the cycle or whose candidate has no education record is a zero. Counted in n_motives and the composition exhibits; not used in the regressions.

continued on the next page

Variable	Definition and source
Panel D. Candidate characteristics	
`cmte_l1`	The candidate's committee assignments in the sitting Congress, as a delimited string with the role in parentheses (Stewart and Woon, 2024).
`n_cmte_l1`	Number of committees held in the sitting Congress.
`cmte_any`	= 1 if `n_cmte_l1` > 0. This is the standard committee proxy of Table 4.
`cmte_gradeable`	= 1 if the candidate holds at least one of the 19 committees the grid covers.
`cand_power_l1`	= 1 if the candidate holds a senior post in the sitting Congress—chair, acting chair, ranking minority member, vice-chair or co-chair of a committee, or Speaker, floor leader or whip: any nonzero `seniorpartymember` code in Stewart and Woon (2024). Displayed as *Powerful politician*.
`cand_ever_power_l1`	= 1 if the candidate has held such a post in any prior Congress.
`cand_ici`	Incumbency status at t from DIME: `I` incumbent, `C` challenger, `O` open seat.
`is_incumbent`, `is_challenger`, `is_openseat`	Indicators from `cand_ici`.
`cand_pty`, `rep_cand`	Party from DIME; `rep_cand` = 1 for Republicans.
`cand_office_st`, `cand_office_district`	State and district number of the seat contested at t.
`reach_breadth`	Candidate–cycle only. Share of the grid's 76 industries over which the candidate's sitting committees hold sectoral jurisdiction: 0 for a candidate with no seat, 0.92 for a member of Energy and Commerce alone.
Panel E. Firm and collapsed variables	
`hq_st`, `hq_st_match_cand`	Headquarters state, and an indicator that it equals the candidate's state. The home-state proxy of Table 4.
`hq_cd_match_cand`	= 1 if any district the headquarters ZIP maps to equals the contested district. The home-district proxy.
`n_cands`	Number of candidates the firm funded in the cycle.
`pac_q`	Quartile of `n_cands` formed across firm–cycles, not across choice cells; medians of 3, 11, 28 and 88 candidates.
`ttl`, `ln_ttl`	Dollars given by the firm, or received by the candidate, in the cycle, and its log.
`n_donors`, `ln_donors`	Number of sample firms funding the candidate in the cycle, and its log.
`n_industries`	Number of distinct GICS sectors among the candidate's donors in the cycle.
`share_sectoral`, `share_geography`, `share_no_motive`	Share of the firm's (or candidate's) donations in the cycle on which the reason fires; `share_no_motive` is the Other-motive share.
`dollar_share_no_motive`	Share of the candidate's cycle receipts contributed by Other-motive donations.
`avail_sectoral`, `avail_geography`	Share of the cycle's own choice set, for that firm, that carried the reason. The benchmark for targeting.
`excess_sectoral`, `excess_geography`	Realised share less available share: targeting above what giving at random within the cycle would produce.

continued on the next page

Variable	Definition and source
Panel F. Firm financials	
From the CCM-linked Compustat annual file, at the firm–cycle level: the fiscal year ending in the cycle's calendar year, one fiscal year per firm–cycle (where a fiscal-year change produces two, the later is kept). Ratios are built only where `at` > 0*; a missing input leaves the ratio missing, and nothing is winsorized in the stored files. The underlying Compustat items (*`at`, `sale`, `oibdp`, `ni`, `dltt`, `dlc`, `ceq`, `che`, `ppent`, `capx`, `xrd`, `dvc`, `emp`, `prcc_f`, `csho`*) are retained alongside each ratio, with* `fyear`, `datadate`, `lpermno` *and the reporting currency* `curcd`*.*	
`ln_at`	log(`at`).
`roa`	`oibdp`/`at`.
`lev`	(`dltt` + `dlc`)/`at`.
`mtb`	(`at` − `ceq` + `prcc_f` × `csho`)/`at`: market-to-book of assets.
`cash_at`	`che`/`at`.
`tang`	`ppent`/`at`.
`capx_at`	`capx`/`at`.
`xrd_at`	`xrd`/`at`, defined only where R&D is reported; missing R&D is never set to zero.
`ln_emp`	log(1 + `emp`).
`ln_mkt`	log(`prcc_f` × `csho`).
`div_payer`	= 1 if `dvc` > 0; missing where `dvc` is missing.

A2 Sample Construction

A2.1 The donation sample

Contributions are itemised FEC records of corporate PAC gifts to federal candidates, aggregated to the firm–candidate–cycle. A cycle runs from the January after the previous general election to the general election in November of the even year, so a gift made in March 2011 belongs to the 2012 cycle. The sample is restricted to House candidates and to donor PACs sponsored by firms with a Compustat identifier, because the second half of this research program requires accounting data. Neither restriction is imposed after a draw: every merge runs before the sample is fixed, so nothing is selected and then discarded.

Candidate attributes come from DIME (Bonica, 2024), joined on the FEC candidate identifier and cycle. Only fields realized before the election are taken: incumbency status, party, district and gender. Vote shares, winner indicators and general-election status are dropped at the point of the merge rather than filtered later, so no downstream step can reintroduce them. DIME's contributor-ideology scores are also excluded: the static CFscore is fitted over the full 1979–2024 history and the dynamic score at cycle t is fitted partly on cycle-t contributions, including the donation being classified.

Committee assignments come from Stewart and Woon (2024) and are lagged one Congress, so a donation in cycle t carries the committees of the Congress elected at $t-2$ and sitting when the gift was made. Party leadership is taken from the same source's senior party member coding: Speaker, floor leaders and whips.

Three features of the raw data are retained rather than cleaned away. Donations at or below zero occur—1,582 net refunds and 2,888 exact zeros—and are kept and flagged, entering every specification except those requiring a logarithm. A firm's headquarters ZIP straddles more than one congressional district in a substantial share of firm–cycles, so headquarters districts are listed rather than chosen among. And a small number of firm–cycles map to two headquarters states, which is a source defect; it is flagged and not corrected.

A2.2 The firm–cycle–district panel

Geography is built rather than read off an address, because a firm's headquarters is one location and its operations are many. The panel records, for each firm and cycle, every congressional

district in which the firm has a qualifying presence.

Establishments come from the Infogroup establishment file, matched to Compustat on ticker and restricted to the cycle's own even year, so a mid-cycle relocation cannot move a firm between districts within a cycle. Each establishment is placed in exactly one district by point-in-polygon against Census TIGER/Line boundary files for the Congress the cycle elected. The vintage rule is the trap in this step and is worth stating: the TIGER release for year Y contains the Congress *sitting* in Y, not the one elected in Y, so the file for cycle Y is the release for $Y + 1$. Getting this wrong in 2012 or 2022 would place firms in boundaries that were never contested.

Headquarters come from SEC filing headers rather than from Infogroup, and the choice is deliberate. Infogroup's coverage of listed firms rises steadily across the window, from under a third in the late 1990s to around three-fifths by 2024, so a geography measure built on it alone would carry a mechanical time trend. The filing-header file has no such gradient. The two sources place a firm in the same district set on 91.3% of firm–years where both are available, and where they differ the median distance is 9.4 kilometres, so the substitution costs little and removes a trend.

The employment floor does real work rather than trimming a tail. Without it, a firm's establishments span a median of 57 congressional districts, which is not a geographic tie to anybody; at 250 employees the median falls to 2. A materiality rule does not fix ubiquity on its own—a national restaurant chain clears any threshold in every district—and no ubiquity screen is applied, on the ground that a chain with a material presence everywhere genuinely has one.

A2.3 The choice set

The choice set pairs every firm–cycle with every candidate–cycle in the same cycle. A candidate enters a cycle's set if at least one sample firm funded them in that cycle, giving a mean of 658 candidates per cycle and 4,880,936 cells in total, of which 285,072 are realized donations.

Motive variables for the passed-over cells are rebuilt from primitives rather than imputed. The committee counts are recomputed by parsing each candidate's committee string and looking each committee up against the donor's industry in the grid; geography is recomputed by joining the firm–cycle–district panel on the contested district. Both use the code that produced the same variables for the realized cells. The build then verifies that the reconstruction reproduces all 285,072 donated rows exactly on `geography`, `n_cmte_sectoral`, `n_cmte_horizontal` and

`n_cmte_noreach`, and halts otherwise. Anything short of exact agreement would mean the counterfactual cells and the realized ones measure different things.

Parsing the committee string requires one piece of care that is easy to miss. Assignments are delimited by commas, and several committee names contain commas—"science, space, and technology"—so a naive split silently drops committees and understates jurisdiction. The split runs on the closing parenthesis of the role suffix instead, and leadership prefixes are stripped before matching.

A2.4 The two collapsed samples

The candidate–cycle sample aggregates donations to the recipient: 7,898 observations recording receipts, donor count, the sectoral spread of the donor base, and the share of donations in each motive category. The firm–cycle sample aggregates to the donor: 7,410 observations recording dollars given, candidates funded, and the share of the firm's donations carrying each reason.

The firm–cycle sample also records what the cycle made available. For each firm–cycle, `avail_sectoral` is the share of that cycle's own choice set carrying jurisdiction over that firm, and `avail_geography` the share carrying a qualifying presence. These are the benchmarks in Figure A5.2: a high realized share is not evidence of targeting for a firm in a heavily regulated industry, and the difference between realized and available is.

Both collapses are conditional on participation. A candidate no sample firm funded is absent from the first, and a firm that funded nobody from the second, so neither speaks to the decision to participate at all. That question is the choice set's.

A3 The Committee × Industry Grid

A3.1 The coding standard

Every cell of the grid answers one question about one (industry, committee) pair:

> Credit a committee only where its remit reaches this industry through a *sectoral instrument*—a statute, programme or regulatory regime whose scope is defined by what this industry makes, sells or operates. Where the instrument is *horizontal*—defined by a legal function and applying to firms in every sector, with only the intensity varying—it is not sectoral jurisdiction, however large the stake. Regulation and government purchase both count, provided the programme doing the buying is specific to what this industry makes.

The operational test is whether a firm in an unrelated industry would describe the same stake in the same words. If it would, the instrument is horizontal. Cells are coded on a three-way scale:

`reach`	Definition	Instrument named?
2	The committee reaches this industry through a sectoral instrument.	required
1	The committee reaches this industry with identifiable force, but the instrument is horizontal.	required
0	No exposure beyond what every firm in the economy faces.	none

The line between 1 and 0 is the requirement to name an instrument and show that it bites this industry particularly. Every committee touches every industry in some remote sense, and that is not a reason to give anybody money; requiring the instrument on the record is what makes the distinction auditable rather than a matter of taste. Each credited cell stores the instrument (`strand`), the part of the industry it reaches where that is not all of it (`segment`), and a note of at most fifteen words.

A3.2 Committee scope

The grid covers nineteen committees: the twenty House standing committees less Ways and Means and Appropriations, plus the Permanent Select Committee on Intelligence.

Ways and Means and Appropriations are excluded because neither has an industry-specific remit to test a firm against, and both are supplied to the analysis mechanically as `cmte_wm_approp`.

Intelligence is included because it holds genuine legislative jurisdiction and is not redundant with the money committees: on the trial sample, 21 of its 23 donation rows are invisible to `cmte_wm_approp`. Joint Taxation is excluded for the opposite reason, its rows being a subset of Ways and Means. Leadership posts are excluded from the grid entirely and recorded as `cand_power_l1`; crediting them would put a firm-invariant fact into the one field whose purpose is firm-specificity.

Industries are the GICS six-digit sub-industries appearing in the sample: 69 in the original build and a further seven added when the sample was extended to the full House population, for 76 in total and $76 \times 19 = 1{,}444$ cells. The increment was judged under the same standard and by the same protocol as the original.

A3.3 Isolation, and why it is the design

Each cell is judged in a context containing no other cell. One agent receives one industry, the standard, and the list of nineteen committees, and returns nineteen rows. The dispatch prompt is byte-identical across the 76 industries except for the industry's code and name, and it is preserved verbatim in the replication files. It contains the coding standard of A3.1, four worked contrasts fixing the sectoral–horizontal line, the three-way code with its field requirements, and two tie-breaking rules: a committee holding both a sectoral and a horizontal instrument for the industry is coded 2 with the sectoral instrument named, and an instrument reaching a substantial named segment of an industry that spans different businesses is credited with the segment recorded. The model is not handed the statutes: it must name the instrument from its knowledge of public law, as specifically as "FDA drug approval and exclusivity" rather than "health," and the named instrument—not the model's authority—is what a reader checks. It receives nothing about any other industry, nothing about any other agent's output, and nothing about how any earlier version of the grid coded its cells. Three rules enforce this: no agent's answers enter another agent's prompt; no earlier grid version is read before a cell is dispatched; and no industry is re-dispatched because its answer is unwelcome.

The last rule is the one that costs something and it is the one that matters. Re-running a cell until it matches an expected number is tuning, and it would destroy the reproducibility the design exists to produce. A file that parses is final.

Isolation buys determinism by construction rather than by measurement. Identical inputs

cannot receive different labels because no cell is judged twice, and no cell's label can depend on the order in which cells were processed, on the length of a context window, or on the labels of neighbouring cells. It also makes the grid re-runnable one cell at a time, so a reader who disputes a single cell can re-judge that cell alone and compare.

A3.4 The ex-ante prediction, and what the run returned

A prediction was written and recorded before the grid was built, so the run would be a test rather than another pass. Four of its components are worth reporting because two were met and two were not.

Budget, Rules, Ethics and House Administration were predicted to return no sectoral cell for any industry, on the ground that none has an industry-specific remit to have one. All four did. That is the prediction that carries information about whether the standard was applied as written, and Figure A5.1 shows what it implies: the three of them that attract material money attract it entirely from industries their jurisdiction does not reach.

Overall density and Energy and Commerce were predicted to fall further than they did. The prediction was 190–240 sectoral cells of 1,311 against a realized 367, and 35–48 cells for Energy and Commerce against a realized 64. The grid was retained as built. It is judged on whether it applies one standard to every cell and names an instrument wherever it credits one, not on the size of its movement from a previous version coded under a different standard, and adjusting it to hit a recorded range would have been the tuning the isolation rule forbids. The prediction is reported here as a recorded prior rather than as a gate that was applied.

Two earlier grid versions are retained in full, together with the cell-level differences between them. The first applied a loose standard to every committee; the second applied a strict standard to Energy and Commerce and the loose one elsewhere, an asymmetry that could not be defended in print. Retaining the diffs is what makes convention-sensitivity measurable: since no register of correct answers exists, the honest statistic is how far the motive distribution moves under a defensible alternative coding, and that requires the alternative to have been kept.

A3.5 Worked examples at each boundary

Sectoral against horizontal, same statute. Clean Air Act Title II certifies an engine as a product before it may be sold and reaches only firms building engine-powered equipment, so Machinery

× Energy and Commerce is a 2. Clean Air Act facility permitting reaches every manufacturing plant in the economy, so where that is all a committee has, the cell is a 1. The seam runs through the statute, not around the committee.

Sectoral against horizontal, same committee. Judiciary is a 2 for Pharmaceuticals, where Hatch-Waxman and the Controlled Substances Act are written for that industry alone, and a 1 for Electric Utilities, where antitrust and bankruptcy are all there is. Education and the Workforce is a 2 for coal-bearing Metals and Mining under the Mine Act, which covers mines and nothing else, and a 1 for a bank under ordinary employment law.

Horizontal against no reach. Chemicals × Education and the Workforce is a 1: OSHA's process safety management standard is written about chemical processes, so an instrument can be named and shown to bite. Software × Education and the Workforce is a 0: ordinary employment law is all there is, and every firm faces it.

A sectoral committee with horizontal cells. Agriculture, about as sectoral a committee as exists, carries eight cells at `reach` = 1: industries it reaches only through commodity-derivatives law, which touches every hedger. Sectoral and horizontal are properties of the pair, not of the committee.

A3.6 What the grid does not establish

No register of correct answers exists for which committee has jurisdiction over which industry, so the grid cannot be scored against ground truth and is not claimed to be. What a reader is entitled to is a single standard applied uniformly, an instrument named wherever a cell is credited, an output small enough to inspect whole, and a measured statement of how much the results move under an alternative coding.

External validation remains outstanding and its design is fixed. A firm's lobbying disclosures name the bills it worked and therefore the committees it treats as having jurisdiction over it, which is revealed preference over exactly the object the grid encodes. The test is whether the grid predicts that contact net of industry and committee fixed effects. Lobbying data must stay out of the grid's construction for the test to mean anything, which is why the grid is built from statutes alone.

A4 Additional Tables

This appendix collects the tables that support the main text without carrying its argument: the sector-level composition behind Section 5.3, the subsample estimates behind Section 6.7, and the motive decomposition and relationship-vintage splits behind Section 8. The supporting figures are Appendix A5.

Table A4.1: **Motive composition by GICS sector**

Sectors are the eleven GICS level-2 sectors, assigned from the firm's historical GICS code in the donation year and ordered by the share of the sector's donations reaching a committee with jurisdiction over the donor's own industry. Shares are of the sector's donations and the reasons are not mutually exclusive. Industry jurisdiction is judged at GICS6 rather than at the sector level shown here, so two firms in the same sector can face different committees. Real estate holds 222 donations from a handful of firms and is reported for completeness. Dollars are nominal.

	Firms	Donations	$m	Mean $	Industry	Tax/spending	Geography	Other motive
Energy	94	18,698	57	3,060	62.5	20.8	9.1	13.3
Communication svcs	56	16,693	60	3,617	59.0	18.8	5.7	14.0
Information tech.	113	16,947	45	2,664	57.0	25.9	5.8	8.2
Industrials	224	61,364	232	3,788	56.4	26.5	10.9	8.8
Real estate	4	222	0	1,466	55.4	17.1	4.5	15.8
Financials	255	43,226	131	3,036	54.8	22.5	9.6	10.0
Utilities	98	25,410	72	2,833	50.6	24.0	7.2	11.7
Health care	182	36,240	111	3,061	49.9	29.5	8.4	11.1
Materials	102	12,970	33	2,565	49.8	25.9	14.7	11.0
Cons. discretionary	175	33,557	99	2,936	48.6	23.3	30.4	8.7
Cons. staples	63	19,745	54	2,718	48.3	25.5	25.4	12.9

Table A4.2: **Where the two motives bite hardest**

Each column is a separate linear probability model on that subsample of the choice set, with firm x cycle and candidate x cycle fixed effects. Quartiles are formed on the number of candidates the firm funded in the cycle: medians of 3, 11, 28 and 88. The base rate of giving ranges from 0.005 in the smallest quartile to 0.170 in the largest, so the coefficients are comparable across columns only after dividing by the mean reported at the foot. Challengers and open-seat candidates hold no committee seat while they run, so the jurisdiction estimate in the last column rests on the small number of former members seeking to return. Standard errors, clustered two ways on firm and on candidate, are in parentheses. Statistical significance: * p<0.10, ** p<0.05, *** p<0.01.

	PAC programme, by quartile				Candidate status	
	(1) Smallest	(2) Second	(3) Third	(4) Largest	(5) Incumbent	(6) Not incumbent
Committee with jurisdiction over the firm's industry	0.0035***	0.0131***	0.0319***	0.0999***	0.0371***	0.0172***
	(0.0004)	(0.0011)	(0.0030)	(0.0069)	(0.0028)	(0.0056)
Geography: firm HQ or a 250+ job plant in the district	0.0866***	0.1430***	0.1660***	0.1480***	0.1898***	0.0552***
	(0.0094)	(0.0139)	(0.0142)	(0.0116)	(0.0114)	(0.0041)
Constant	0.0023***	0.0099***	0.0266***	0.1244***	0.0553***	0.0115***
	(0.0002)	(0.0005)	(0.0013)	(0.0025)	(0.0015)	(0.0002)

Observations	1,306,566	1,164,843	1,209,783	1,199,744	3,199,684	1,678,042
R-squared (within)	0.019	0.020	0.018	0.016	0.017	0.005

Table A4.3: **The six motives separately**

As Table 11, with the measured-motive count split into its six categories. The motive counts partition the R-winner total and the Other-motive count is omitted, so the coefficient on *R winners funded* is the per-winner value of an Other-motive winner and each motive coefficient is the premium of that motive relative to an Other-motive winner. The categories are collinear with the total and the small ones are noisy (cross-sectional standard deviations: jurisdiction 19, tax and spending 7, geography 5, economy-wide 3, leadership 0.8, social tie 0.5), so the measured motives are not statistically separable from one another. Heteroskedasticity-robust standard errors in parentheses. * p<0.10, ** p<0.05, *** p<0.01.

	2016-cycle connections		2014-cycle connections	
	(1) GICS2	(2) GICS6	(3) GICS2	(4) GICS6

R-squared	0.305	0.293
N	616	594

A5 Additional Figures

This appendix collects the figures that support the main text without carrying its argument: where each committee's corporate money comes from and how far a sector's realized giving departs from what its choice set offered, both behind Section 5.3, and the dose-response display behind Section 6.6.

Figure A5.1: **Where each committee's corporate money comes from**

For each of the nineteen graded committees, the share of the corporate PAC dollars received by its members that comes from industries the committee reaches through a sectoral instrument, from industries it reaches only as it reaches every industry, and from industries it does not reach. Dollar totals are at the right. The grid never observes a donation, so the alignment is a consistency check on the grid rather than a construction of it.

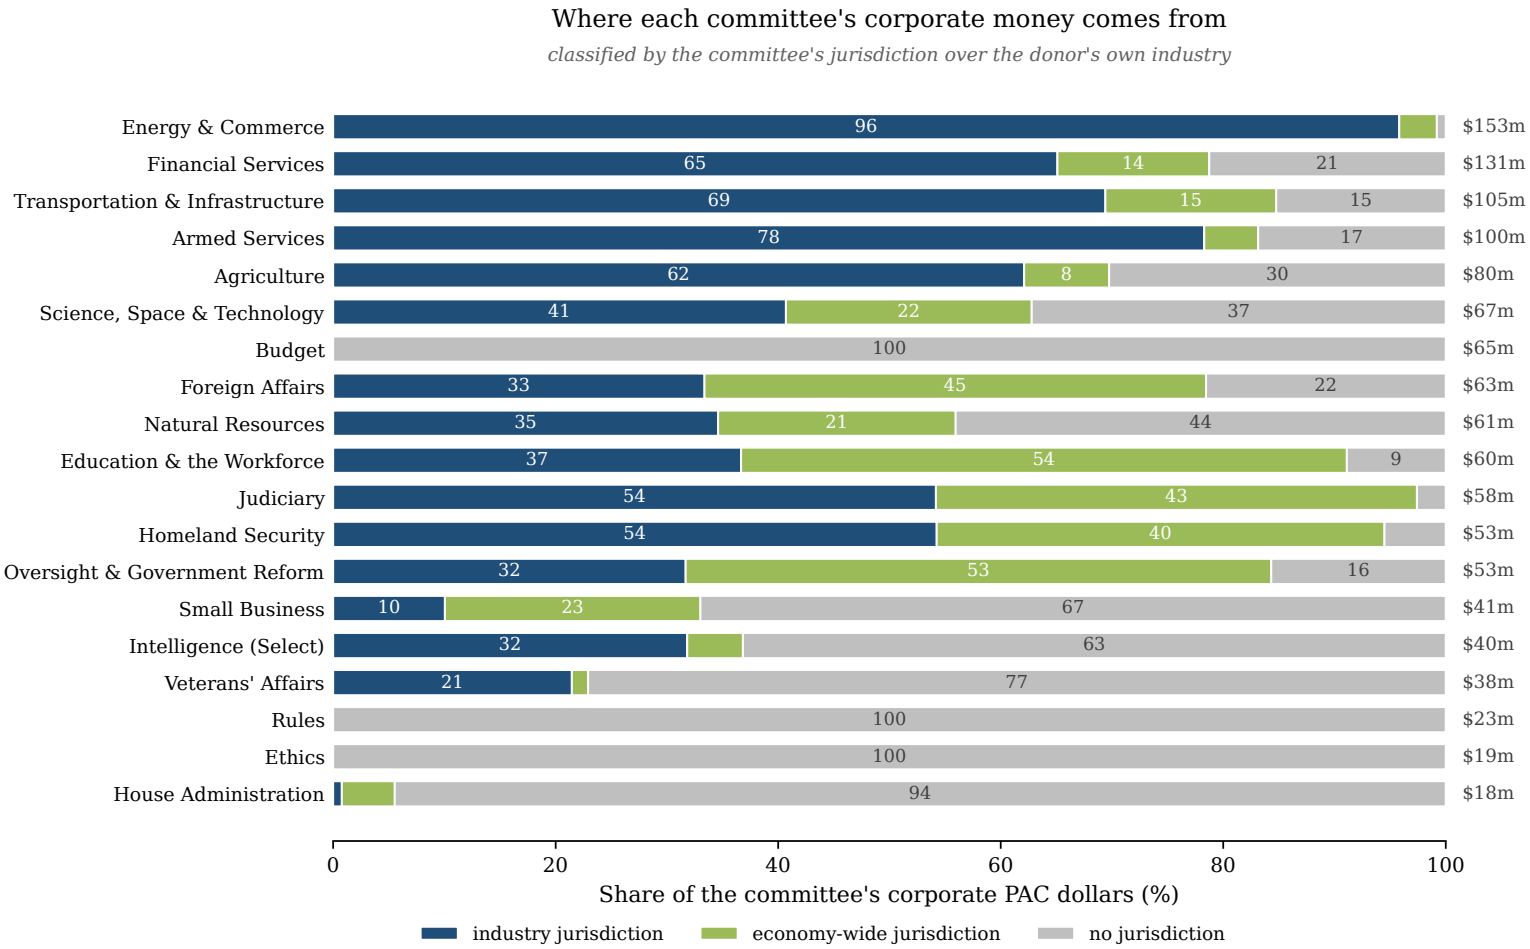

Figure A5.2: **Targeting against what the choice set made available**

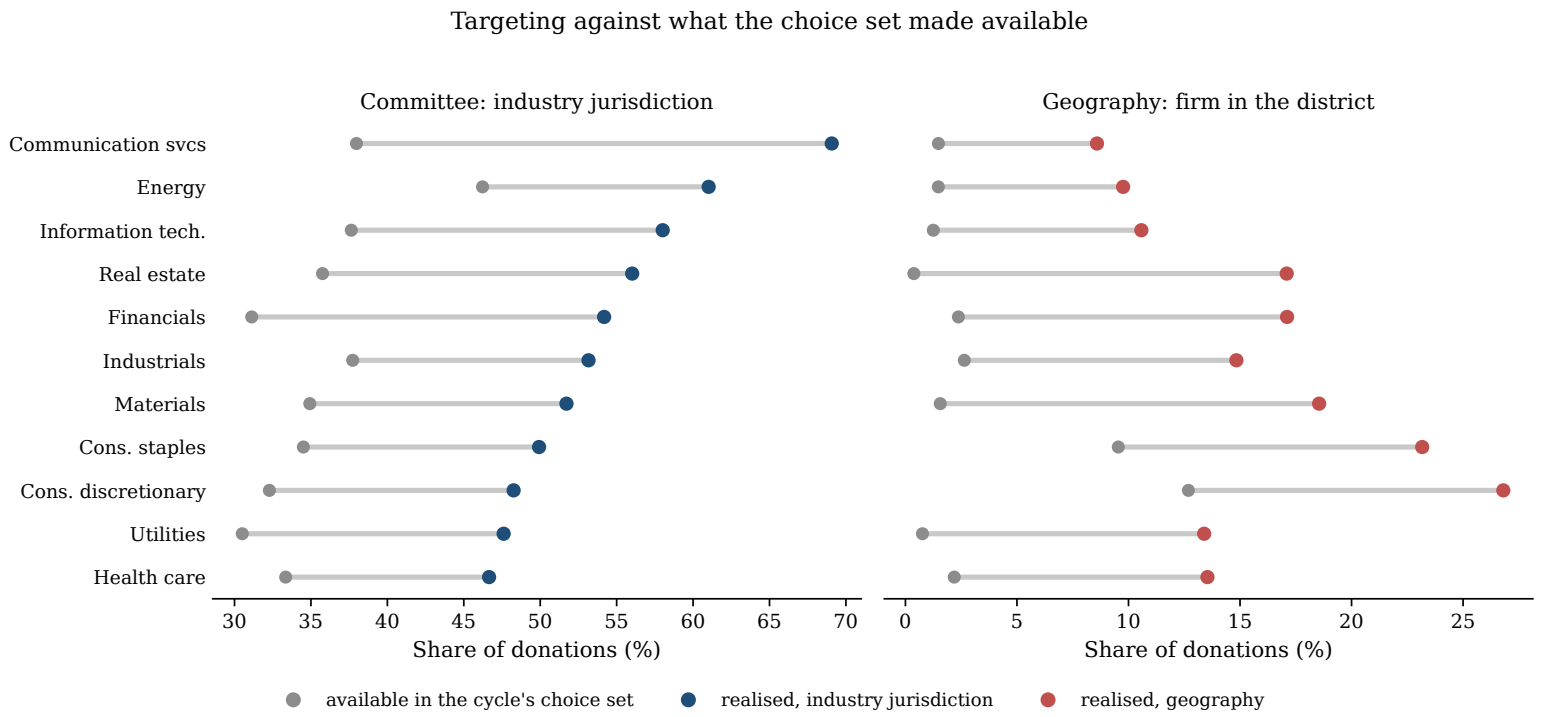
Grey marks the share of the cycle's own choice set that carried the reason for the average firm in the sector; the colored mark is the share of that firm's realized donations that did. The gap is targeting above what giving at random within the cycle would produce.



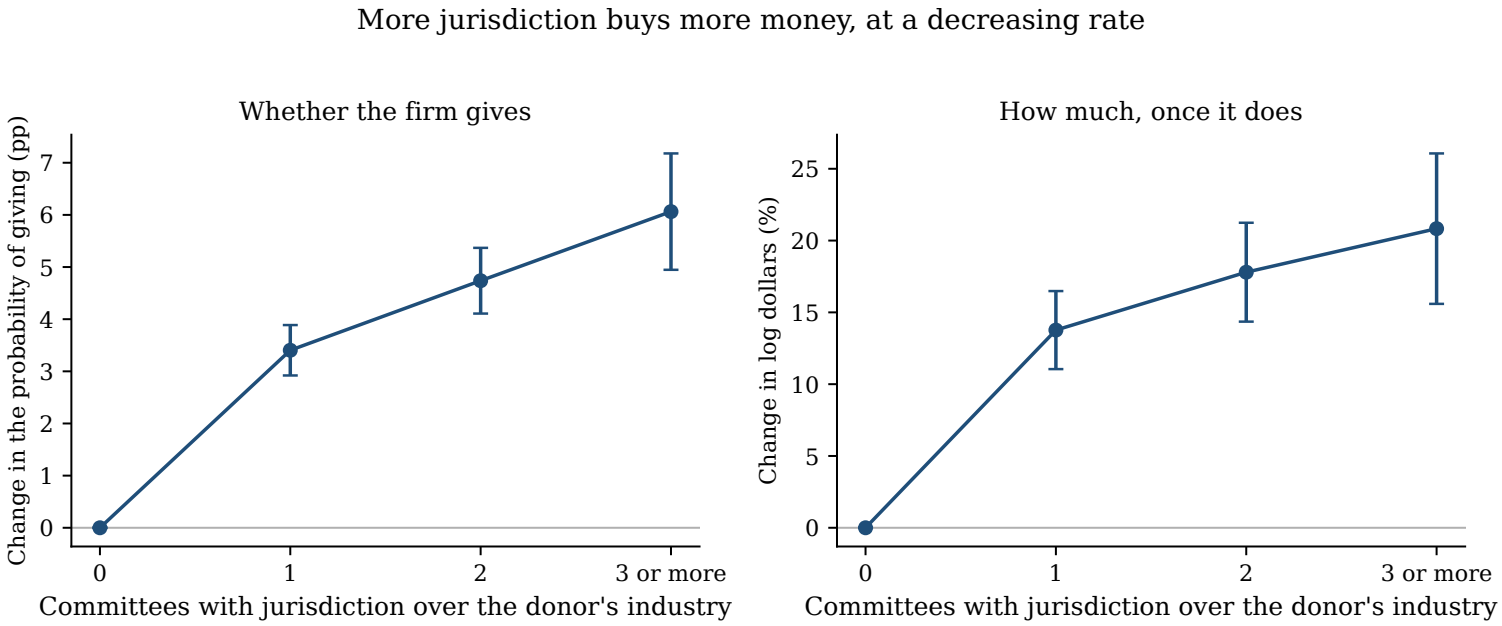


Figure A5.3: **More jurisdiction, more money**

Coefficients on indicators for the number of the candidate's sitting committees that reach the donor's own industry, with zero omitted, from the specifications of Table 5 column 3 (left) and column 6 (right). Bars are 95% confidence intervals from standard errors clustered on firm and on candidate.

Conversations with the AI Agent

Why Firms Fund Politicians: Recovering Motives with Large Language Models

AFA 2027 Special Session on Papers Written with Generative-AI Workflows
Documentation (1): a text of all conversations with AI

Conversations with the AI

Every exchange with the agent was recorded. This appendix reproduces the initial prompt, indexes the sessions, and states what the complete transcript contains and where it sits.

A6.0 Eligibility

The call requires that the investigation begin on or after 1 June 2026 with an initial prompt to an LLM or AI agent, and that the paper be submitted by 31 August 2026. Both conditions are met, and the record is datable to the day.

The initial prompt reproduced below was given on **22 July 2026**, seven weeks after the eligibility date. Nothing in this paper predates it: there was no prior draft, no prior sample, and no prior code. The first artifact of any kind is the sample-construction do-file the author wrote on 22 July, the same day, in response to the design the prompt set out. The first recorded agent session opened on **27 July 2026** and the last closed on **31 August 2026**, the submission date. The eleven session transcripts indexed in Section A6.2 span exactly that window, and their timestamps are machine-generated rather than reconstructed.

Two components of the project draw on material that predates the window, and neither is a research input the call would exclude. The donation and candidate data are third-party datasets — the FEC contribution records as compiled by DIME, Compustat, CRSP, and the congressional committee assignments of Stewart and Woon (2024) — assembled during the window from sources that of course existed before it. The close-election template of Section 8 of the paper is a do-file from an earlier paper of the author's, supplied to the agent as a specification to follow and identified as human-authored in Section 3 below.

A6.1 The initial prompt

The project began on 22 July 2026 with the prompt below, given before any code or data existed. It is reproduced verbatim from the author's contemporaneous record (`Prompt Record.docx`), which also holds the first taxonomy exchange with the coauthor.

> Now let's create the Claude.md file for this project.
>
> Firms give money to political candidates, and we can see the money, but not the reason. The research question is to leverage an LLM to read firm-politician-cycle triad observations and use all available information to infer and classify the primary motive behind them. We may later link the LLM-generated motives to financial outcome variables to examine whether and how much firms benefit from their political donations. The specific motive category will be provided later as the project proceeds, because we may try different sets of categorical values.

> The sample is a firm-politician-cycle panel — one row per firm, per politician, per election cycle. We may try to create the sample from firm donation samples used for other projects and saved in my drive. I restrict the analysis to Compustat firms because the financial side of the paper needs accounting data. Donations here mean corporate PAC donations to candidates unless we change the analysis target later for this project. We will either use the data on political candidates saved on my drive or the ones you find for the exercise.
>
> One thing about this design we should avoid is look-ahead bias. If the model classifies motive using whatever it knows or can look up, it knows how things turned out — including the outcomes I plan to use as dependent variables. That makes the second half of the paper partly circular. We need to avoid this and make classification prompts and exercises restrict the model to information available before the election date of that cycle, and I want you to tell me whenever something in the code or the prompt design quietly relaxes this. Ideally, the LLMs recover the primary motives based on data in other datasets and information as of the corresponding election dates, so we know the analysis does not rely on ex-post or look-ahead information.
>
> We will first use a trial sample of 1000 observations to test and fine-tune the prompt before applying it to a full sample analysis. The ultimate target of this project is that the output lands in a top 3 finance or top 5 economics journal, so accuracy and economic rigor are crucial for our analysis.
>
> A few habits I want you to keep. Don't impute a missing financial variable or drop rows on your own. If you need to pull Compustat or any more data, we should confirm it. When an identifying assumption is thin, say plainly instead of writing around it — I'd rather hear the weak link named. And when a result looks good, the useful response isn't that it's interesting; it's what would have to be true for it to be wrong.

Three commitments in that prompt shaped the paper and can be checked against it: the ban on look-ahead information, which the grid design satisfies by construction (Section 3.4 of the paper); the instruction to name a thin identifying assumption rather than write around it, which Section 8.3 of the paper and the limits paragraph of Section 1 of the paper discharge; and the instruction never to impute or drop data unilaterally.

A6.2 Index of recorded sessions

Eleven sessions were recorded between 27 July and 31 August 2026. The counts below are computed from the transcripts themselves by `scripts/archive_sessions.py`. A "human turn" is a message the author typed; a "tool call" is an action the agent took (reading a file, running Stata, writing code).

Session	Span (UTC)	Records	Human turns	Tool calls
`be55af56`	2026-07-27 to 07-30	2,569	79	456
`e46c5e60`	2026-08-11 to 08-12	2,734	93	445
`807e833a`	2026-08-12	74	4	12
`aa231988`	2026-08-12 to 08-13	2,035	88	338
`7720c9c6`	2026-08-13	467	3	93
`05bea4a3`	2026-08-13	494	8	147
`3403fa82`	2026-08-13	128	8	13
`2323b62d`	2026-08-13	1,696	40	296
`d2afb1a2`	2026-08-13 to 08-24	7,527	166	1,481
`92be0468`	2026-08-14 to 08-26	6,710	460	854
`a888bf8f`	2026-08-28 to 09-01	5,112	99	510
Total		29,546	1,048	4,645

A6.3 The complete transcript

The complete record is the eleven `.jsonl` files in `sessions/`, 76 MB and 29,546 records, copied verbatim from the agent's own logs and versioned with the project. Each record carries a timestamp, the role that produced it, the message text, and, for agent records, the tool called and its full input and output.

Rendered as readable prose, the conversation proper — the author's turns and the agent's replies, excluding the machine-generated payloads of the 4,645 tool calls — runs to roughly 430,000 words. Including the tool payloads, which contain every file the agent read and every table it produced, the record runs past four million words. The conversation proper is supplied with this submission as a companion PDF; the raw `.jsonl` archive accompanies it, since it is the only form in which the record is complete and machine-checkable.

Two features of the record are worth stating because they bear on reproducibility. First, the classification work itself is not in these transcripts: the committee-by-industry grid was produced by dispatching each of the seventy-six industries to a separate agent under a byte-identical prompt, and those prompts and outputs are preserved in `Guidance/` and `Data/20260812/` rather than in the conversation. Second, the transcripts include the agent's errors and the author's corrections — a mislabeled sample, a fixed-effect specification that absorbed the treatment, a citation whose details had to be pulled from the author's reference manager rather than from the model's memory. They are left in.

The complete conversation

What follows is every message the author typed and every reply the agent wrote, in order, across the eleven sessions indexed above. It is generated mechanically from the agent's own session logs and reproduced verbatim. Actions the agent took appear as single labelled lines naming the tool and its target; their full inputs and outputs, several million words of file contents and program output, are preserved in the `.jsonl` archive. Non-ASCII characters are transliterated for typesetting; the archive preserves them exactly. Nothing has been edited or removed, including the agent's errors and the author's corrections of them.

```
================================================================================================================
COMPLETE RECORD OF CONVERSATIONS WITH THE AI AGENT
Why Firms Fund Politicians -- AFA 2027 special session, documentation (1)
================================================================================================================

This is the conversation proper: every message the author typed and every reply the agent wrote, in order,
across eleven sessions between 27 July and 31 August 2026. Actions the agent took are recorded as single
labelled lines naming the tool and its target; their full inputs and outputs, which run to several million
words of file contents and program output, are in the .jsonl archive that accompanies this submission.
Nothing has been edited or removed, including the agent's errors and the author's corrections of them.

--- AGENT   [2026-07-27 05:54:15] ----------------------------------------
I've read the do-file, the log, and both output files. Here's what they are.

## The pipeline (`sample_1000_firm_candidate_obs_max100_per_firm.do`)

Five chunks, all `joinby ... unm(both)` merges off a donation master:

1. **Sample.** Start from `gvkey_cand_don_cycle_data_cycle_2000_22.dta` (520k firm-candidate-cycle rows),
```

keep House candidates (386,503), cap each firm at 100 randomly-ordered rows (96,212), then draw **500 PA-seat + 500 non-PA** observations = 1,000.
2. **Candidate details** from the DIME ICPSR crosswalk (house seats only) -- all 1,000 match.
3. **House committee assignments** (Stewart-Woon style file) by `cand_id`x`cycle` -- 1,554 matched rows + 199 unmatched kept, flagged by `has_committee_info`.
4. **Firm HQ** (`hq_st`, `hq_cd`, `hq_district`) by `gvkey`x`cycle`.
5. **Historical GICS** (2/4/6-digit) + `conm` by `gvkey`x`year`, with `year = cycle`.

Then `drop if hq_st == ""` (-532 rows) -> 1,928 rows saved to `.dta` and `.csv` (identical, 33 columns).

What the CSV actually contains

The unit of observation is not firm-candidate. It's firm x candidate x cycle x **committee assignment** x **HQ congressional district**. Both of the last two multiply rows:

- 1,928 rows = **700 unique firm-candidate-cycle triples** (464 firms, 327 candidates, 12 cycles 2000-2022).
- Committee expansion: one row per candidate committee seat that Congress.
- HQ expansion: the HQ file is firm-cycle-**district** level, not firm-cycle. 282 of 633 firm-cycles carry 2-6 distinct `hq_cd` values (Navistar 2002 appears in IL-7, -9, -13, -14). This looks like a ZIP->CD crosswalk where the HQ ZIP straddles districts, so "the firm's district" is genuinely ambiguous in the data.

Anyone (or any model) reading this row-by-row will see the same firm-candidate donation repeated up to 16 times.

Variables, by block:

Block	Variables	Notes
Firm	`gvkey`, `conm`, `hq_st`, `hq_cd`, `hq_district`, `hist_gics2/4/6`	70 rows missing GICS; `hq_district` has 6 zeros and 3 `98`s
Candidate	`cand_id`, `cand_nm`, `district_in_dime`, `cand_pty`, `cand_office_st/district`, `cand_ici`, `gwinner`	91% incumbents (`I`), 6% open, 3% challengers; 90% general-election winners; 99 blank `gwinner`
Donation	`gvkey_cand_ttl_don_cycle`, `gvkey_cand_don_qtr_count`, `earliest_gvkey_cand_d_cycle_qtr`, `earliest_polcon_cycle_qtr`, `gvkey_cand_don_nth_cycle`, `l_gvkey_cand_ttl_don_cycle`	median $2,000/cycle at the triple level; 25 rows <= 0 (refunds, min -$2,400); lagged donation non-missing for only 737 rows
Committee	`congress`, `committeecode`, `committeename`, `seniority`, `seniorpartymember`, `committeestatusatendofthis`, `rankwithinpartystatus`	226 rows (139 triples) have none

Six things to settle before this feeds an AI motive assay

1. **It's 700 triples, not 1,000.** The `count == 1000` assertion runs *before* the merges; the HQ drop then removes 300 triples' worth of rows, and that attrition (firms absent from the HQ file) is not random.
2. **PA is 50% of the sample by design** (base rate is 4,961/96,212 ~= 5%). Deliberate, but any rate computed on this file -- "share of donations to home-state candidates," etc. -- is not a population quantity.
3. **The seed is in the log but not in the do-file.** The executed version had `set more off` / `set seed 20260722` after `clear all`; the file on disk doesn't. As it stands the script won't reproduce the CSV.
4. **Geography, the most obvious "constituent motive" signal, is weak here.** HQ state matches candidate state in 28.8% of rows; HQ *district* matches in 3.5% -- and that number is contaminated by the multi-district HQ issue above.
5. **Three committee variables need their codebook before they can be described to a model.** `seniority` is 0/1 (mean 0.117) where the source variable is usually a continuous rank; `seniorpartymember` takes values {0, 11, 12, 13, 21, ..., 64}; `committeestatusatendofthis` takes {1,2,3,6,7,8}. I won't guess at these.
6. **What's absent for motive classification:** candidate ideology (CFscore/DW-NOMINATE -- `bonicarid` and `icpsr2` are dropped in Chunk 2), race competitiveness or vote share, committee-jurisdiction<->industry mapping, firm financials or regulatory exposure, and PAC identity.

The header comment also points at `2026.07 Motives for Pol Donation`; the live folder is `2026.07 AI - Political Donation Motive`.

Tell me what the assay is meant to do with each row -- classify a single donation's motive, or rank motives within a firm -- and I'll say whether this row structure and variable set can support it, or what the collapse/augmentation should be.

--- AUTHOR [2026-07-27 05:59:21] --
The first change I want to make is we don't need to have 500 PA observations in the csv, so you can update the code and reproduce the extracted sample to it a random one.

--- AGENT   [2026-07-27 06:02:21] ----------------------------------------
Done -- the PA quota is removed and the sample is regenerated.

## Code changes (`sample_1000_firm_candidate_obs_max100_per_firm.do`)

- **Chunk 1** now draws 1,000 observations in one unstratified pass (`sort overall_draw` -> `keep in
1/1000`). The `preserve`/PA-split/`append` block and the `pa_sample`/`non_pa_sample` tempfiles are gone; the
per-firm cap of 100 and the House restriction are unchanged.
- **Restored `set more off` and `set seed 20260722`** -- these were in the executed log but missing from the
file on disk, so the previous version wasn't reproducible.
- **Fixed `output_dir`**, which pointed at `2026.07 Motives for Pol Donation` (renamed since); it would have
failed to save.
- Added `tab cand_office_st, sort` to the end diagnostics.

Ran it in batch (Stata 17 MP, `D:\Stata17`); the log is clean and the `.dta` and `.csv` are overwritten.

## New sample vs. old

| | old (PA-forced) | new (random) |
|---|---|---|
| Rows | 1,928 | **1,792** |
| Unique firm-cand-cycle | 700 | **690** |
| Firms / candidates | 464 / 327 | **479 / 455** |
| PA share of rows | 51.7% | **4.7%** |

PA now sits at 4.1% of triples against a 5.2% eligible-pool benchmark -- a normal draw at this n. The
candidate count jumping from 327 to 455 is the real gain: the old file kept re-drawing the same small set of
```

PA House members.

Everything else holds steady, including the two structural points from before:

- **1,000 sampled observations still deliver 690 triples.** The `count == 1000` assertion runs before the merges; `drop if hq_st == ""` then removes 556 rows at the expanded level. Firms missing from the HQ file drop out systematically, not at random.
- **Rows still multiply by committee x HQ-district** -- 1,792 rows over 690 triples, up to 16 rows for one firm-candidate-cycle. Unchanged by this edit, but it's the thing to fix before any per-row AI assay runs.

Geographic overlap is essentially the same as before (27.3% same state, 4.0% same district), so removing the PA concentration didn't cost the home-district signal.

--- AUTHOR [2026-07-27 06:11:19] ----------
Ok the deliverables for this project is for this call for paper (https://afajof.org/news/call-for-papers-afa-2027-special-session-of-paper-written-with-generative-ai-workflows/). A brief presentation will be based on a trail exercise with the sample we just creeated in one week. Two questions for the AFA call for paper: 1. I feel the most chanllenging requirement for the AFA call for paper is "All conversations with AI, including the initial prompt, must be documented and submitted (as appendices) along with the final paper.". What's the best practice to meet the requirement? Is it better to use Claude Desktop rather than Claude code for this task? 2. Is it a best practice for this call of paper to fine tune the prompt to the best possible one so that we only have fewer promopt interaction times so that documentation file won't be extremely lengthy?

--- AGENT [2026-07-27 06:11:24] ----------
Let me read the actual call first -- the answer turns on its exact wording.

--- AGENT [2026-07-27 06:13:25] ----------
Let me check whether the sample-construction work has a transcript, since that bears directly on your answer.
[action] Bash: cd "$HOME/.claude/projects" && for d in */; do n=$(ls "$d"*.jsonl 2>/dev/null | wc -l); if
↪ ["$n" -gt 0]; then latest=$(ls -t "$d"*.jsonl 2>/dev/null

--- AGENT [2026-07-27 06:14:13] ----------
Two things from the call that reframe both questions, then the answers.

The metric is human effort, not AI autonomy. The call says: *"The ideal paper is not one with no human involvement, but with maximal quality per unit of human effort."* Selection is on *"both the research contribution and the design and effectiveness of AI use in the workflow."* The three-part documentation ideal is *"(1) a text of all conversations with AI, (2) a time log of human activity, and (3) a report on the fraction of project lines (code, writing, and documentation) that were contributed by humans as opposed to AI."*

The submission deadline is August 31, 2026 -- five weeks out. (These are the quotes the fetch returned; confirm the page directly for page limits and format, which I couldn't extract.)

There's already a hole in your record. The investigation must *"begin on or after June 1, 2026 with an initial prompt provided to an LLM or AI agent."* Your do-file is dated 2026-07-22, and there is no transcript anywhere on this machine covering it -- the only session for this project is today's, and the supply-chain-politics project's last session was July 8. So the sample construction is currently undocumented work. Settle this before anything else: either it was hand-written (declare it as pre-existing data infrastructure, and start the documented investigation from a clean initial prompt), or it came from a session elsewhere that you need to recover.

1. Claude Code, and it isn't close

Claude Code already writes the artifact the call is asking for. This session is on disk at `~/.claude/projects/G--OneDrive---...-Political-Donation-Motive/be55af56-....jsonl` -- 156 records, every user and assistant message timestamped to the millisecond, every tool call with its arguments and result,

plus `cwd` and `version` on each record. Requirement (1) is satisfied automatically, and requirement (2) -- the time log -- falls out of the timestamps rather than being reconstructed from memory.

The deciding argument is requirement (3), the human-vs-AI line fraction. Desktop can't run Stata, can't reach WRDS through `psql`, can't open your `.dta` files. Working there means copy-pasting code out of chat into Stata and pasting results back -- and **every one of those round trips is human labor that leaves no trace in the transcript**. It inflates your human fraction while making it unmeasurable. Desktop maximizes exactly the quantity the call penalizes.

Best practice on top of that:

- **Put the project under git today** and commit the current state as a baseline. This is the only mechanical way to answer (3): agent commits carry `Co-Authored-By: Claude`, your commits don't, and `git log --numstat` turns the fraction into a query instead of an estimate. Without version control from the start, you will be guessing in the appendix.
- **Copy the JSONL into the project folder after every session.** This is the highest-risk failure mode in the whole plan -- those files live outside your OneDrive, and a reinstall or cleanup loses the one artifact you cannot reconstruct. Automate it with a Stop hook.
- **Capture subagent transcripts too.** They're flagged `isSidechain` in the same tree and they are unambiguously "conversations with AI." If you delegate WRDS pulls to the specialist agents, those conversations are part of the record.
- **Keep a human-activity log.** The call explicitly permits direct human contributions but requires documenting them. When you edit a do-file yourself or run something interactively in Stata, it needs a line in a file. Nothing else will catch it.
- **Decide the redaction policy now, not in August.** Tool results in that JSONL contain data dumps and absolute paths with your name. Truncate tool *outputs* to a stated character limit; never truncate prompts.

2. No -- do not compress the transcript by engineering fewer prompts

It fails on both halves of the criterion.

On human effort: hours spent hand-crafting one perfect mega-prompt are human effort, and they land in your time log as a large block with no output attached. Twenty cheap turns where the agent does the work cost less human effort than one prompt you spent three hours polishing. You'd be shortening the appendix by inflating the exact denominator you're judged on.

On workflow evidence: the transcript is the primary exhibit for "the design and effectiveness of AI use." A short transcript with one monolithic prompt and a finished paper demonstrates nothing about workflow -- worse, it reads as though the human did the thinking offline and the AI typed it up. A long transcript showing the agent proposing constructions, running its own diagnostics, catching an error, and being redirected at genuine forks is the demonstration. Length here is evidence, not cost.

There's also a trap to avoid deliberately: iterating prompts in a scratch session and submitting only the polished one. Under *"all conversations with AI... must be documented,"* those scratch sessions are conversations. Don't build a two-tier record.

What to optimize instead:

- **Front-load durable context into `CLAUDE.md` and skills.** This is the strongest move available to you. It cuts per-turn human effort, it's amortized across the whole project, and it reads to a discussant as workflow engineering rather than prompt-polishing -- the standing conventions in your global `CLAUDE.md` are already this, and they're documentable as designed infrastructure.
- **Let the agent run long autonomously** rather than micro-steering each step.
- **Treat length as a formatting problem.** Organize the appendix by session with a one-page index and a summary table (session, date, duration, purpose, files touched); put full transcripts in a machine-readable supplement. Discussants will grep it, not read it linearly.

Your instinct that documentation is the binding constraint is right, but it binds on *fidelity and completeness*, not volume. The cheap insurance is mechanical: git plus an automated transcript export, set up before the trial exercise rather than after.

Want me to set up the git repo and write the export script that turns the JSONL into the appendix format? Both are small, and having them running during next week's trial is what makes the trial informative about the real submission.

--- AUTHOR [2026-07-27 06:22:18] ----------
I also feel AFA cares about paper quality since it doesn't have so many spots for presentation, so documentation of interactions is important but I feel priproty is quality of the findings. In terms of documentation, I doubt someone will painstakingly check each log and documentation files, so as long as the documentation largely looks like we primarily use AI for this project, it would be fine to meet their

requiremnt. What do you thinl? Given this, what's the best practice for my works on this project.

--- AGENT [2026-07-27 06:23:19] ----------

You're right on the prioritization, and mostly right on the second point -- but one part of it is worth separating out.

Where I agree

Quality first. Four presentation slots means selection is dominated by the research contribution; the AI-workflow criterion is a filter and a tiebreaker, not the thing that gets you in. And documentation should not consume your five weeks. That's precisely why I'd make it *automatic* -- a Stop hook copying the JSONL and a git repo cost about two hours once and then zero, versus reconstructing a time log in late August from memory. The goal is for documentation to cost you nothing, not for it to be impressive.

Where I'd push back, on practical grounds

Two things make "as long as it looks like AI did it" a bad bet specifically here.

Scrutiny is inverted from your model. Unselected papers get skimmed. But the four selected ones get a human discussant whose explicit assignment is to evaluate the *nature of the human labor embodied in the paper*. Characterizing your human input is literally that person's job, in front of the audience, at the session. If you're optimizing to be selected, you're optimizing into the scrutiny -- and the artifacts are machine-readable, so a mismatch between the time log, the git history, and the transcripts is far more visible than an inconsistency buried in prose.

More to the point: you have nothing to gain. The call says the ideal paper *"is not one with no human involvement, but with maximal quality per unit of human effort,"* and that humans *"are allowed to make direct contributions... but these contributions should also be documented."* Your research judgment -- choosing the question, killing a bad design, deciding what the measure should be -- is permitted, expected, and not disqualifying. So shading the record buys you a benefit you already have for free, at a cost that lands exactly where you'd care about it. The honest version of your record is also the more impressive one: "here is a 5-week project where the human contributed 12 hours of research direction and the agent did the rest" is a stronger claim than an unfalsifiable "the AI did everything."

The workable rule: **do the work in the agent so the record is true by construction, rather than curating a record after the fact.** That's cheaper than either alternative.

Best practice for this project

Documentation (do once, this week, then forget). Git repo initialized and the current state committed as baseline; Stop hook copying session JSONL into the project folder; a human-log text file you append a line to whenever you touch Stata or a file directly. Export script written now, run in August.

Quality -- and here's the thing I'd worry about most.

Your trial has a specific vulnerability that a week of work could waste. In the CSV as it stands, an LLM classifying the motive behind a donation sees `hq_st`, `cand_office_st`, `committeename`, `cand_pty`, `cand_ici`, `hist_gics`, and the amount. **A regression sees the same variables.** If the AI's motive assignment is just a nonlinear function of covariates you already have, the measure has no information content, and the referee-equivalent question -- "what does this buy over a logit on home-district match and committee assignment?" -- kills the paper. This is a `gate-measure` problem, and it fires before any design work.

So the week-one trial should not aim to show the pipeline runs. It should aim to answer: **does the AI motive assignment contain anything beyond the observables?** That's cheap and decisive:

1. Collapse to the 690 firm-candidate-cycle triples (the committee x HQ-district duplication has to go, or you'll pay for it in tokens and corrupt every aggregate).
2. Classify a few hundred with the LLM.
3. Regress the motive label on the structured covariates. If R? is near 1, the measure is redundant and you redesign now rather than in week four.

If it is redundant, the fix is to give the model information the covariates don't carry -- the candidate's actual legislative activity, the firm's regulatory exposure, bill or hearing text, contemporaneous news. That's where an AI measure can beat a dummy variable, and it's the version of this project that could plausibly be an AFA paper rather than a demonstration.

The framing precedent is the consumption-versus-investment motive literature -- Ansolabehere, de Figueiredo and Snyder's "Why Is There So Little Money in U.S. Politics?" is the canonical statement of the puzzle your measure would speak to. I'd want to verify that citation and survey what's been done since before it goes

```
near a draft, but positioning against that puzzle is what makes the question important rather than merely
feasible.

Want me to start with the collapse-and-validate trial, or set up the git repo and hook first? The hook takes
twenty minutes and everything after it is documented automatically, which argues for doing it first.

--- AUTHOR  [2026-07-27 06:30:06] ----------------------------------------
1. Yes, let's set up the git repo. 2. WHat will be my best practice to interact with you for this project,
e.g., order of prompts, working habits, etc?

--- AGENT   [2026-07-27 06:30:45] ----------------------------------------
Setting up the repo now. I'll make the history honest from the first commit -- the do-file as it existed
before this session goes in as a human-authored baseline, then my edits on top.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && git --version && echo "--- identi

--- AGENT   [2026-07-27 06:42:26] ----------------------------------------
Repo is live -- `bc3076c`, 8 files. One thing needs your hand:

**`scripts/archive_sessions.py` was blocked** by the permission classifier, because it reads Claude Code's
own transcript directory (`~/.claude/projects/...`). That's a reasonable thing to guard, and I'd rather you
approve it than route around it. Run it yourself:

```
! python scripts/archive_sessions.py
```

It copies each session `.jsonl` into `sessions/` and writes an index table. If you'd like it to run
automatically at the end of every session, say so and I'll wire it as a Stop hook in project-level settings.

Also: `HUMAN_LOG.md` has two rows with `?` in the minutes column -- your July 22 sample-building time and
today's. Only you know those.
```

How to work with me on this project

Front-load a project `CLAUDE.md`. This is the highest-return hour you will spend. There isn't one yet. Every hour of context you put there is amortized across all five weeks *and* reads to a discussant as deliberate workflow engineering rather than prompt-polishing. It should hold the research question and its RAP spine, the data dictionary for the sample, decisions already made and why, and a tombstone list of what's been killed. When I start cold in session six, that file is the difference between me re-deriving your project and me working on it.

One session, one question. Session boundaries are now appendix chapters -- a session that wanders across five topics is unreadable as evidence and produces worse work anyway. Open each one by stating the question and the decision it will resolve, close it with `wrap-up`. Don't `/clear` mid-question; it fragments the transcript file.

Give me the objective and the constraint, not the procedure. "First collapse to triples, then run a logit on X, then tabulate" converts your research judgment into typing -- and the transcript reads as dictation, which is the worst possible look for this venue. "I need to know whether the AI motive label carries information beyond the observables; you design the test" produces better work and better evidence. Spend your specification budget on the things only you can decide.

Make the forks visible, in the transcript, with a one-line reason. Which measure, which sample, whether a design is dead -- those are yours. But decide them *here*, not silently offline followed by an instruction. The one-line reason is what makes your human-effort story legible; without it, a discussant sees an agent producing output and can't tell whether you were steering or watching.

Before accepting any result, ask me what would kill it. Cheap, and a transcript containing that exchange is precisely what the workflow criterion rewards. Keep the standing rule that every regression gets an ex-ante prediction in the same sentence as its result.

Commit per unit of work. My commits carry the `Co-Authored-By` trailer, yours don't, and requirement (3) becomes a `git log` query instead of an August guess.

Order for the next week

The trial presentation should report a *verdict*, not a demo. That dictates the sequence:

1. **Question first.** Write the project `CLAUDE.md` with me: what does this paper claim, and what does the AI measure buy that a logit on `hq_st`-match, `committeename`, and `cand_ici` doesn't? Everything downstream depends on this answer, and it is not a technical question.
2. **Gate the measure before building it.** `gate-measure` on the motive construct -- definition screen and the redundancy threat -- *before* any classification runs. If the measure can't beat the covariates in principle, no amount of pipeline work saves it.
3. **Then build:** collapse to the 690 triples, classify a few hundred, run the redundancy diagnostic.
4. **Verdict session:** what the trial shows, and whether the design survives to the real submission.

One thing worth deciding now: **this project's documented investigation currently opens with "I've extracted a csv..."**, which is a thin initial prompt for something the call singles out. You can't rewrite history, and `PROVENANCE.md` records it accurately -- but you *can* open the next session with a proper framing prompt stating the question, the constraint, and the deliverable, and that becomes the substantive opening of the research record.

Want to start there? Writing the project `CLAUDE.md` and pinning down what the AI measure is supposed to buy is the right first session, and it's the one that determines whether the other four weeks are worth spending.

--- AUTHOR [2026-07-27 06:44:42] --
Where should I run "! python scripts/archive_sessions.py"?

--- AGENT   [2026-07-27 06:44:56] --
Right here -- type it into this Claude Code input box, at the start of a line. The `!` prefix runs the command in this session, so the output lands in the conversation (and therefore in the transcript, which is a small bonus: the archiving step documents itself).

The session's working directory is already the project root:

```
G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation Motive
```

so the relative path `scripts/archive_sessions.py` resolves correctly with no `cd` needed.

If you'd rather use a normal terminal, this works too:

```
cd "G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation
Motive"
python scripts/archive_sessions.py
```

Either way it prints one line per transcript found and writes `sessions/INDEX.md`.

One thing to expect: run now, it copies this session's `.jsonl` as it currently stands -- mid-session, so it won't include anything after this point. That's harmless, since re-running later overwrites with the fuller file. It's the reason a Stop hook is the better long-run answer: it fires at the end of each session and always captures the complete file.

<bash-input> python scripts/archive_sessions.py</bash-input>

--- AUTHOR [2026-07-27 06:45:13] ----------
<bash-stdout>copied be55af56-340f-45e1-9bb6-2e2b82770d63.jsonl (257 records)
wrote G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation
Motive\sessions\INDEX.md</bash-stdout><bash-stderr></bash-stderr>

--- AGENT [2026-07-27 06:45:18] ----------
Worked -- 257 records now (it was 156 when I profiled it earlier; the session has grown). Let me check the index and commit it.
[action] Read: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
↪ Political Donation Motive/sessions/INDEX.md
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
↪ Political Donation Motive" && git add -A && git commit -q -F -

--- AGENT [2026-07-27 06:45:39] ----------
One correctness issue worth fixing immediately: git wants to rewrite line endings in the `.jsonl` on checkout, which would make the archived transcript no longer byte-identical to the original. For an evidentiary artifact that matters.
[action] Write: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
↪ Political Donation Motive/.gitattributes
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
↪ Political Donation Motive" && git add -A && git commit -q -F -

--- AGENT [2026-07-27 06:46:04] ----------
Archived and committed. `text: unset` confirms git will now leave the transcript bytes alone.

Repo state -- three commits:

`bc3076c`	Baseline: sample code, data, provenance scaffolding
`8c631c4`	Session `be55af56` transcript
`948cdbb`	`.gitattributes` -- byte-exact transcript preservation

The index reads: 257 records, 6 human turns, 46 tool calls, 05:50-06:44 UTC. That ratio is the kind of thing the AFA appendix is asking you to be able to state, and it now falls out of the record instead of being reconstructed.

Two loose ends before the research work starts:

1. **`HUMAN_LOG.md` still has `?` in both minutes columns** -- your July 22 sample-building time and today's reading/thinking time. Worth filling in while you still remember; that column is requirement (2) and it's the one thing no artifact can reconstruct for you.
2. **Re-run the archive script at the end of each session**, or let me wire the Stop hook so it's automatic. Right now the committed transcript stops at 06:44 and everything since is uncaptured until the next run.

When you're ready, the first real session is the project `CLAUDE.md` and the question it has to answer: what does an AI motive label buy over a logit on home-district match, committee assignment, and incumbency status? That answer determines whether the remaining weeks are worth spending, so it's worth spending a session on before any classification code exists.

--- AUTHOR  [2026-07-27 21:46:35] ----------------------------------------
Now let's create the Claude.md file for this project.
Firms give money to political candidates, and we can see the money, but not the reason. The research question
is to leverage an LLM to read firm-politician-cycle triad observations and use all available information to
infer and classify the primary motive behind them. We may later link the LLM-generated motives to financial
outcome variables to examine whether and how much firms benefit from their political donations. The specific
motive category will be provided later as the project proceeds, because we may try different sets of
categorical values.
The sample is a firm-politician-cycle panel -- one row per firm, per politician, per election cycle. We may
try to create the sample from firm donation samples used for other projects and saved in my drive. I restrict
the analysis to Compustat firms because the financial side of the paper needs accounting data. Donations here
mean corporate PAC donations to candidates unless we change the analysis target later for this project. We
will either use the data on political candidates saved on my drive or the ones you find for the exercise.
One thing about this design we should avoid is look-ahead bias. If the model classifies motive using whatever
it knows or can look up, it knows how things turned out -- including the outcomes I plan to use as dependent
variables. That makes the second half of the paper partly circular. We need to avoid this and make
classification prompts and exercises restrict the model to information available before the election date of
that cycle, and I want you to tell me whenever something in the code or the prompt design quietly relaxes
this. Ideally, the LLMs recover the primary motives based on data in other datasets and information as of the
corresponding election dates, so we know the analysis does not rely on ex-post or look-ahead information.
We will first use a trial sample of 1000 observations to test and fine-tune the prompt before applying it to
a full sample analysis. The ultimate target of this project is that the output lands in a top 3 finance or
top 5 economics journal, so accuracy and economic rigor are crucial for our analysis.
A few habits I want you to keep. Don't impute a missing financial variable or drop rows on your own. If you
need to pull Compustat or any more data, we should confirm it. When an identifying assumption is thin, say
plainly instead of writing around it -- I'd rather hear the weak link named. And when a result looks good,
the useful response isn't that it's interesting, it's what would have to be true for it to be wrong.

--- AGENT   [2026-07-27 21:47:21] ----------------------------------------
Before I write this, let me verify one thing in the data that bears directly on your look-ahead constraint.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk" && python -c " import pandas

--- AGENT   [2026-07-27 21:47:48] ----------------------------------------
Confirmed, and it matters: **cycle 2000 maps to Congress 107, which is seated in January 2001 -- after the
November 2000 election.** Every committee variable in the current sample, plus `gwinner`, describes the
Congress the election *produced*. Feeding those to the classifier would be exactly the leakage you want
flagged, and it's already sitting in the trial file.

--- AGENT   [2026-07-27 21:49:18] ----------------------------------------
`CLAUDE.md` is written and committed (`d6bad1c`).

**A `Prompt.docx` appeared in the folder and git couldn't read it -- Word has it locked.** Two things: it's
untracked, so tell me if you want it in the repo. More importantly, if you're drafting classification prompts
in Word, that's the undocumented-human-effort pattern worth avoiding -- prompt development done outside the
agent produces no transcript, and it's the one form of human labor the AFA appendix most wants to see. Better
to draft prompts as a versioned `.md` in the repo, or in-session.

## What I put in the file, and what I decided

Most of it transcribes your brief. Three places where I did something you should check:
```

The look-ahead contamination is already in your trial sample, and I verified it rather than assuming. Cycle 2000 maps to Congress 107, seated January 2001. So `committeename`, `seniority`, `rankwithinpartystatus`, `seniorpartymember`, `committeestatusatendofthis`, `congress`, and `gwinner` all describe the Congress the election *produced*. A donor giving in March 2000 saw the 106th. The fix is to lag committee data one Congress and drop `gwinner` from anything the model reads -- but that means rebuilding the sample, so it's a real task, not a filter.

I named parametric leakage as unsolved rather than handled. Restricting the prompt controls the input, not the weights. A model asked about a 2012 donation knows who won. Instructing it to ignore what it knows is unverifiable, and I'd rather not let the paper rest on that instruction -- so the file lists three diagnostics (name/year masking, counterfactual records, models with straddling cutoffs) and marks them as not yet run. This is the deepest threat to the design and I don't want it recorded as solved.

I recommended a stricter cutoff than you specified, flagged as an open decision. You said "before the election date of that cycle." Donation date is stricter and more faithful -- the motive forms when the check is written, and an election-date cutoff admits up to two years of information the donor didn't have. It matters here: first donations spread across all eight quarters (89 triples in Q1, 81 in Q8), and Q8 straddles the election itself. I've written donation-date as the recommendation, not the decision.

The provisional RAP has `A` marked TBD deliberately -- the answer is what the LLM recovers, and writing it before we have it is how these projects go wrong.

Your call on the cutoff is the next thing that blocks work, since it determines what the record can contain. After that, the first gate: does the LLM label carry information beyond home-district match, committee, party, and incumbency?

--- AUTHOR [2026-07-27 21:57:12] ----------

1. The Prompt.docx no need to be tracked. 2. I will tell you my thoughts on classificaiton later and we will decide it togther. 3. We will adjust the sample you will use for this analysis, which will not include the following committee information. 4. Understood " Restricting the prompt controls the input, not the weights." and I will try to advoid it in my prompt. 5. Since we want to focus on the firm-candidate-cycle level analysis, I didn't use donation date as the cutoff as the data has been aggregated to this level. We may layer use raw donation data for this analysis, but for now let's stick to the firm-candidate-cycle level sample and the cycle election date as the cutoff to make the analysis work easier.

--- AGENT [2026-07-27 21:57:32] ----------

Noted on all five. Two file updates, then one substantive flag on point 3.

[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/.gitignore

[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/CLAUDE.md

[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/CLAUDE.md

[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && git add .gitignore CLAUDE.md && g

--- AGENT [2026-07-27 21:58:30] ----------

Both recorded and committed (`78c1ddb`). A new untracked **`Prompt Record.docx`** has appeared -- the ignore rule only names `Prompt.docx`. Say the word and I'll broaden it to `*.docx`.

One flag on point 3, then I'll drop it

Excluding committee data doesn't make the model unaware of committees. It makes the model fall back on *its own memory* of who sat on what -- which is uncontrolled, unverifiable, and almost certainly of post-election vintage. That's the parametric leakage you just agreed is the harder problem, and dropping the column feeds it rather than starving it.

Supplying **t-1 Congress** committee data explicitly is the tighter control on both fronts: it's genuinely pre-election (the donor observes the sitting member's current seat), and it anchors the model to a record instead of a recollection. Dropping the column solves the contamination I found -- the t-Congress assignments -- but the fix for that was the lag, not the deletion.

The cost of deleting is concrete: a classifier with no committee input cannot distinguish "access to a committee with jurisdiction over this firm's industry" from "same-state incumbent," which is the distinction the paper's positioning rests on.

It's your call and I've recorded it as decided. But it's cheap to reverse later, and I'd rather you make it knowing the mechanism runs the opposite way from how it looks.

Where things stand

Committed, four decisions locked: election-date cutoff, no committee data, categories open, sample to be rebuilt.

Blocked on you: the motive categories, and the sample adjustment. Once I know the category set, the first thing worth running is the gate question -- whether the LLM label carries information beyond home-district match, party, and incumbency. With committee data out, that test gets *more* important, since the covariate set the label has to beat is now small enough that redundancy is a live risk.

I have not touched the sample yet, and won't until you tell me what the adjusted version should contain.

--- AUTHOR [2026-07-27 22:08:29] ----------
1. I renamed Prompt.docx to Prompt Record.docx. It's the same file. 2. Yes, I agree that we will use t-1 Congress committee data and other data as of the election date for the analysis. Actually the first thing we're going to do is to update the current do file to create an updated sample that doesn't not include election result and House committe information in the sample. The new sample will be purely firm-candidate-cycle donation information and firm related information (We will use a separate committe and election result data to provide such information). My idea is we can remove Chunk 3 code in the do file and regenrate the sample. Will this give the clean sample that doesn't include election result and committee information? You can keep the current do and dta file as a copy.

--- AGENT [2026-07-27 22:08:44] ----------
Good question to ask before running it. Let me verify where each variable actually originates rather than infer from the file order.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -c "
↪ import pandas as pd for lbl, p in [('DONATION MASTER','202
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -c "
↪ import pandas as pd for lbl, p in [('DONATION MASTER','202

--- AGENT [2026-07-27 22:09:51] ----------
No -- removing Chunk 3 alone won't do it. I checked the source files rather than inferring from position:

`gwinner` comes from the **DIME crosswalk in Chunk 2**, not the committee file. Chunk 2's `drop` list omits it, so it survives. The election result would stay in your "clean" sample.

The donation master itself is clean -- its 14 variables are all pre-election (`cand_ici`, `cand_pty`, office/district, and the donation aggregates).

So the minimal edit is three things, not one:

1. **Delete Chunk 3** (as you propose).
2. **Add `gwinner` to Chunk 2's `drop` list.**
3. **Fix line 180**, `sort cycle gvkey cand_id committeecode committeename` -- those variables no longer exist and Stata will error out. It becomes `sort cycle gvkey cand_id`.

But that still won't be a firm-candidate-cycle sample

Two structural things survive Chunk 3's removal, and both need your call before I run anything.

The HQ merge duplicates rows, not the committee merge. Chunk 4 joins a firm-cycle-*district* file: 282 of 633 firm-cycles carry 2-6 HQ congressional districts (Navistar 2002 sits in IL-7, -9, -13, -14 -- a ZIP straddling district lines). Removing Chunk 3 drops you from 1,792 rows to roughly 1,000-ish, but still with the same donation repeated across HQ districts. Not one row per triad.

The sample lands near 700, not 1,000. `drop if hq_st == ""` runs *after* the `count == 1000` assertion, so firms missing from the HQ file are drawn and then discarded.
[action] AskUserQuestion:

--- AGENT [2026-07-27 22:13:03] ----------
What would you like me to clarify?

If it helps aim it, the parts most likely to need unpacking:

- **Why a firm has multiple HQ congressional districts at all** -- whether that's a data defect I should investigate and fix upstream, versus a genuine ambiguity we have to live with. I've assumed the latter from the pattern (a ZIP straddling district lines), but I haven't opened the HQ source file to confirm how `hq_cd` was built. That's worth doing before you choose, and it might make the question moot.
- **What the district variable is actually for** -- I'm treating it as the input to a home-district/constituent motive, which is why I care about preserving it. If your motive categories won't lean on district-level geography, the simple `hq_st`-only option gets much more attractive.

```
- **What "exactly 1,000" is worth** -- the restructure changes *which* observations get drawn, so the trial
sample would no longer overlap much with what you have now. If you'd rather keep continuity with the current
sample, that's a real reason to accept ~700.

Or something else entirely -- tell me what's unclear and I'll reframe.

--- AUTHOR  [2026-07-27 22:14:56] ----------------------------------------
I think we can have the information on the corresponding CDs of HQ in the sample, which is not election
result and committee assignment information. Maybe we can make the CD information in one row for my HQ so
that we will still only have 1000 rows if our trail aims to have 1000 firm-candidate-cycle observations

--- AGENT   [2026-07-27 22:15:07] ----------------------------------------
Let me open the HQ source first -- I flagged that I hadn't, and it determines how the collapse should work.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2024.12 Supply
      ↪  chain - politics/Data/20250829" && python -c " import pandas
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2024.12 Supply

      ↪  Political Donation Motive/AI Talk/sample_1000_firm_candidate_obs_ma
      [action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research
      ↪  projects\2026.07 AI - Political Donation Motive\AI Talk"; & "D:\Stata17\Sta

--- AGENT   [2026-07-27 22:18:00] ----------------------------------------
The log shows the *old* output -- 1,792 rows and the old filename. Something didn't pick up the rewrite. Let
me check what's actually on disk.
      [action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research
      ↪  projects\2026.07 AI - Political Donation Motive\AI Talk"; Get-ChildItem | S

--- AGENT   [2026-07-27 22:18:17] ----------------------------------------
False alarm -- the new files exist (`random_1000_house_firm_cand_cycle_don_firm_info.dta/.csv`, 6:18 PM).
Stata's batch process detaches from PowerShell, so my `Get-Content` read the log before it was rewritten.
Reading it now:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk" && grep -nE "^r\([0-9]+\);|n

--- AGENT   [2026-07-27 22:18:42] ----------------------------------------
Ran clean at exactly 1,000 rows -- but there's a bug I need to fix: `hq_cd_match_cand` is 0 for all 1,000
observations, which is impossible (the old sample had 4% district matches).

The cause: `hq_cd_list` holds 4-digit state+district codes (`1707`), and I compared them against a 2-digit
district string (`07`). Never matches. The `hq_cd_label` field (`IL-07`) is the right one to match on.
      [action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk/sample_1000_firm_candidate_obs_ma
      [action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research
      ↪  projects\2026.07 AI - Political Donation Motive\AI Talk"; $p = Start-Proces
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk" && python -c " import pandas

--- AGENT   [2026-07-27 22:19:32] ----------------------------------------
Fixed and verified -- `hq_cd_match_cand` is now 3.9% (39 observations), matching the 4.0% in the old sample.
Ball Corp (HQ CO-02) donating to Mark Udall in CO-02 correctly flags as 1.

Updating the orientation file, since its data section is now stale:

```

--- AGENT [2026-07-27 22:20:21] ----------
Done. `AI Talk/random_1000_house_firm_cand_cycle_don_firm_info.{dta,csv}` -- **exactly 1,000 rows, one per firm-candidate-cycle** (`isid` passes), 599 firms, 573 candidates.

Direct answer to your question: removing Chunk 3 alone would not have worked. `gwinner` comes from the DIME crosswalk in Chunk 2, so the election result would have survived. It also would have crashed at line 180, where `sort` still referenced `committeecode`. Both fixed.

HQ districts are now one row with the districts listed, as you asked:

Field	Example
`hq_cd_list`	`0629, 0632, 0638`
`hq_cd_label`	`CA-29, CA-32, CA-38`
`hq_cd_n`	`3`

39% of the sample has 2-4 districts. I kept both formats because the raw codes merge and the labels read -- and any district-level construction has to match on `hq_cd_label`. That distinction bit me: my first version compared 4-digit `hq_cd` codes against 2-digit district numbers and returned zero matches for all 1,000 rows. Caught it because 0% was impossible against the old sample's 4%. Now 3.9%, and Ball Corp (HQ CO-02) -> Mark Udall (CO-02) flags correctly.

One change beyond what you asked, easy to revert: I added `hq_st_match_cand` (21.5%) and `hq_cd_match_cand` (3.9%). Both are pure pre-election geography, and they're the covariates the LLM label will have to beat at the gate. Say the word if you'd rather build them downstream.

Two things to know about the sample:

The merges now run *before* the draw, so you get 1,000 complete observations instead of 1,000 drawn and ~700 surviving. This means the drawn observations differ from the previous sample -- it's a fresh draw, not a filtered one.

`hq_st_n > 1` for 1.5% of rows: a firm-cycle mapping to two HQ states (MoneyGram shows `MN-03, MN-05, TX-30`). I flagged it rather than fixing it, since I don't know whether it's a relocation within the cycle or a crosswalk error. Worth a look before the full sample.

Old do-file, log, and sample are in `AI Talk/_archive/` with a `_20260727` suffix. Everything committed at `1d1d0bd`.

Next is yours: the motive categories, and whether committee data comes back in lagged form.

1. The raw data on political candidate information I provide for the analysis is G:\OneDrive - The Pennsylvania State University\PhD research projects\1.Common Dataset\Politics\2.Complied Data by Others\Database on Ideology, Money in Politics, and Elections\Raw Data. You may need to use other data of information to infer primary donation motives, which you will find yourself. You can keep this in our Claude.md as well. We will next determine the categorical values we're going to use for your analysis. 2. I want you to make 1-3 latex slides on the trail sample creation and general information, such as, 39% of the sample has 2-4 districts, average donation amount etc. You can refer to to make the slide G:\OneDrive - The Pennsylvania State University\PhD research projects\2024.12 Supply chain - politics\Slide\2025.11 PSU\pol_supply_psu.tex. We don't need to put too much information on the slide or make many pages. The goal is to give the audiance a general picture of what we did to create the trail sample and how it looks like before we dig into the real analysis.

Both done.

## Slides -- `Slide/trial_sample.tex` (+ compiled PDF, 3 pages)

Matched to your PSU deck's style (maroon frametitles, `\widehrulefill`, `\bi`/`\ei`, mathpazo). Compiles
clean with zero overfull boxes.

1. **Building the Trial Sample** -- the funnel (520,011 -> 386,503 House -> 285,074 with firm data -> 76,385
after the cap -> 1,000 drawn), then what's deliberately excluded and why.
2. **What the Model Reads: One Observation** -- the MGM Resorts -> Shelley Berkley row laid out as the
classifier will see it. I added this frame because it makes the design concrete in a way summary statistics
can't: the audience sees there's no vote share, no winner, no committee seat.
3. **What the Trial Sample Looks Like** -- donations, candidates, relationships, firms and geography, with
the 39% multi-district point as the closing note.

Cut it to two frames by dropping #2 if time is tight, though I'd keep it.

## DIME source recorded -- with two traps worth your attention

The path is in `CLAUDE.md`, with the 64 columns sorted by what a donor could observe. Two things in that file
would quietly break your constraint:

**CFscores are estimated *from* contribution data.** `recipient.cfscore` is fitted over the whole 1979-2024
history -- look-ahead by construction. Worse, `recipient.cfscore.dyn` at cycle *t* is fitted partly on
cycle-*t* contributions, which include **the very donation being classified**. Using it would make
ideological alignment mechanically correlated with the donation. The t-1 dynamic score is the usable one.
Same caution for `dwdime`, `irt.cfscore`, `composite.score`.
```

```
**Fundraising totals are full-cycle**, including money raised after the election -- `total.receipts`,
`total.pac.contribs`, `num.givers`. A pre-election version needs building from the underlying contribution
records.

Also useful: `district.pres.vs` (district presidential vote share from the *prior* race) is a legitimate
pre-election measure of district partisanship -- probably the best competitiveness proxy available to you
without construction work.

One hygiene note: `cand_pty` carries `Rep` (2 obs) alongside `REP`, plus `DFL` for Minnesota. Trivial,
unfixed, recorded.

Committed at `46bcf91`. Next is the motive categories.

--- AUTHOR  [2026-07-28 00:18:04] ----------------------------------------
My coauthor and I came up with the following five primary motives:
1.    Geography: the candidate is contesting the representative of the district where a firm's HQs are located
2.    Committees: the committee the candidate sits on is related to the business areas or appropriations of
the firm
3.    Incumbent or contestant: if the candidate is an incumbent House representative or a new contestant, who
may sponsor legislation directly the firms
4.    Social ties: the candidate has social ties with the executive of the firm. We will leverage BoardEx
data on executive backgrounds (you can pull BoardEx data via WRDS) and you will need to find the data for
political candidate backgrounds.
5.    Others: Other things can be lumped into this category, but we should try to restrict the assignment of
this category because it will be less useful for me.
If you think the motive of one donation meets multiple categories above, select the higher-order one.

While I'm writing down these categories, I have two questions and would like to ask you first before going
back to my coauthor:
1. We say we don't want to use forward-looking data to infer donation motives, but should we consider the
subsequent committee membership because those members will be related to business areas or appropriations of
the firm? Or is it the case that most committee memberships are very stable, so candidates and firms can
easily predict whether a candidate will be on a specific committee in the next Congress? I know most election
results are very predictable.
2. My coauthor was on the fence about whether we should use "policy - i.e. bill sponsors of legislation
directly affecting the firm". Eventually, he thinks we should use this "incumbent or contestant" category. He
has several top finance journal publications on finance and politics, so I trust his judgement. My question
is what he wants this third category to capture and why he eventually leans to "incumbent vs. contestant"? Is
this category very different from the first two categories and why? When we were brainstorming the
categorical values we should use, we obviously wanted to balance the number and the distance between each
categorical value, so we eventually did not use more detailed categorical values.

Also, do you have any other questions about categorical values? I think after we settle this issue, we can
begin the first-round analysis.

--- AGENT   [2026-07-28 00:19:18] ----------------------------------------

A GICS4->committee jurisdiction crosswalk already exists for the other project
(`gics4_house_cmte_crosswalk_1993_2022.dta`, 25 industries x 41 committee links) -- that's your category-2
indicator, already built.

# Q1: Committee stability -- measured

From the 103rd-117th Congresses:

| | |
```

```
|---|---|
| P(member returns next Congress \| serving now) | **0.835** |
| P(same committee next Congress \| holds it now **and** returns) | **0.806** |
| P(same committee next Congress \| holds it now, unconditional) | **0.678** |

But the average conceals the thing you actually care about. Persistence conditional on returning, by
committee:

| High | | Low | |
|---|---|---|---|
| Ways and Means | 0.976 | Small Business | 0.586 |
| Energy and Commerce | 0.976 | Budget | 0.598 |
| Appropriations | 0.973 | Homeland Security | 0.646 |
| Armed Services | 0.894 | Science, Space, Technology | 0.722 |
| Financial Services | 0.876 | Veterans Affairs | 0.737 |

**The committees a firm would plausibly target are the near-deterministic ones.** Tax (Ways and Means), broad
regulatory jurisdiction (Energy and Commerce), and spending (Appropriations) sit at 97-98%. These are the
"exclusive" committees members fight to get onto and never leave. The churn is concentrated in the
low-prestige committees where a donation-access story is least plausible anyway. Churn also spikes after wave
elections -- 0.703 in the 111th, 0.709 in the 103rd -- which is worth knowing but doesn't change the
conclusion.

**So: use t-1, never t.** And the reason I'd give your coauthor is not primarily about leakage -- it's that
**t-1 is the more correct measure of motive.**

Motive is about what the donor expected. A firm that gives to a Ways and Means member in March who then gets
bumped in January still made a committee-motivated donation; coding it from the realized assignment would
call it something else. Realized assignment measures what happened; lagged assignment measures what was
intended. You want the latter.

The leakage argument is the second one, and it's decisive for the paper's back half: if committee motive is
coded from post-election assignment, and your outcome variables depend on the firm having a connected
committee member, then classification and outcome share the same realization. That's circularity you'd never
get past a referee.

The cost of using t-1 is bounded and quantifiable -- you can report the 0.806 and 0.976 figures as a
validation that the donor's information set was a good forecast. That's a footnote that strengthens the paper
rather than a limitation you concede.

# Q2: What category 3 is doing

Reconstructing his reasoning -- I can't read his mind, but four things point the same way:

**Why he moved off bill sponsorship.** (1) It's realized after the donation, so you'd need t-1 sponsorship
anyway. (2) Using it requires a firm-specific bill-relevance mapping -- matching legislative text to
individual firms is a whole separate measurement paper that would swallow this one. (3) Most importantly,
**it collapses into category 2**: bills affecting a firm move through the committee with jurisdiction over
that firm, so sponsorship is largely a within-committee refinement, not a separate axis. You said you wanted
distance between categories; sponsorship isn't distant from committees.

**What he's replacing it with.** Categories 1 and 2 are *relational* -- they define a link between this firm
and this candidate (my district, my industry's jurisdiction). Category 3 is about **the candidate's position
in the legislative process, independent of the firm**: do they hold power now, or are they seeking it? That's
the generic-access motive, and it's the first-order empirical regularity in corporate PAC giving -- PACs give
overwhelmingly to incumbents regardless of district or committee. Neither 1 nor 2 captures it, and omitting
it would push a large mass into "Others," which you want to avoid.

That's a defensible call. Three problems with it as written, though.

**It lumps two opposite motives.** Giving to an incumbent buys access to power that exists. Giving to a
challenger or open-seat candidate tries to *change* who holds power -- an electoral or ideological
investment. Those predict opposite things in your outcome analysis, and a category containing both has no
directional interpretation. Either split it, or keep one category with incumbent/contestant recorded as a
separate field so you can split it later at zero cost.

**It's defined by absence, so it becomes the residual.** 90.5% of your sample are incumbents. Under a
priority rule where 1 beats 2 beats 3, category 3 means "not my district, not my committee, but they hold a
seat." That's a real motive -- generic access -- but the label doesn't say so, and the bucket will be large
and heterogeneous. I'd name it what it is.
```

The tie-break rule is in tension with the LLM's whole contribution. This is the one I'd raise with him first. Three of your five categories are computable from structured data you already have: district match (I built `hq_cd_match_cand` -- 3.9% of the sample), incumbency (`cand_ici`), and committee jurisdiction (t-1 committee data x the GICS4 crosswalk that already exists). If the priority order is fixed, the label becomes a deterministic function of those three indicators and **the LLM is a very expensive lookup table.**

The model's distinct capability is exactly the thing the priority rule removes: adjudicating which motive dominates when several apply. Suggested fix, which costs nothing -- have the model score all five and report its own ranking with reasoning, then apply the priority rule as a separate deterministic post-step. You end up with both labels, and the disagreement between the model's judgment and the mechanical rule is a *result*, not a nuisance. It's also the natural answer to the referee who asks what the LLM bought you.

My questions before you go back to him

The priority order needs stating explicitly. "Select the higher-order one" is ambiguous -- I read it as 1 beating 2 beating 3, but it could mean the opposite. It determines the entire distribution, so it should be written as an ordering, not a phrase.

Where does party/ideology go? A firm that gives to co-partisans everywhere isn't captured by any of the five and would land in Others. The consumption-versus-investment framing (Ansolabehere-de Figueiredo-Snyder) makes exactly this the central dichotomy in the literature. Deliberate omission on the grounds that corporate PACs are pragmatic, or an oversight?

Where does leadership go? Speaker, majority/minority leader, whips. Not geography, not committee jurisdiction, and calling it merely "incumbent" understates it.

"Others" is conflating two things. A different motive versus not enough information to tell. You want Others minimized -- but forcing a guess to avoid it is worse than recording uncertainty, because you can't later distinguish the confident classifications from the coin flips. Split it, and have the model emit a confidence score.

Category 4 will be very small. BoardEx-to-politician matching on education, employer, and board overlap is a low-hit-rate exercise; expect low single digits. Congressional Bioguide is the natural source for politician backgrounds (official, free, has education and prior occupation). Worth deciding now whether social ties is a *category* or a *flag* that can coexist with another motive -- as a category competing under a priority rule, it may almost never fire.

One structural note: category 2 is mechanically unavailable for challengers and open-seat candidates, since they hold no committee. That's fine, but it means motive availability differs across the sample, which matters if you compare motive distributions by incumbency.

Once the priority order and the Others/confidence question are settled, the first-round analysis is ready to run -- and the first thing worth running is whether the model's label beats the three mechanical indicators.

--- AUTHOR [2026-07-28 01:23:06] ----------
1. I agree with your suggestions on the two opposite motives of Incumbent vs contestant. I think we can keep one category with incumbent/contestant and record as a separate field so that I can later separate these two. 2. Your summary of the priority rule is correct. 3. Regarding your comment on the tie-break rule, my idea is to ask you to infer the political donation motives with some data I provid, so I don't want you to restrict yourself to the data I provide and actually want you to look at outside to determine the motive if you're not certain about your classification of one firm-candidate-cycle donation observation. I think the rule should be if you're not certain about one classification, you can search any available information to determine the classification. 4. Yes, we can have explitict priority order after we confirm all categorical values. One key question for now is whether you think I should have other categorical values or not. My coauthor thought about the party/ideology one but eventually didn't have it in the current version. Do you think if we should have it give the project purpose? Simiarily, would it be better if I have a separate leader category? I think "others" can hold both cases of A different motive and not enough information to tell, but I want to restrict the frequency of this category because this category is not very informative won't be very helpful for my follow-up analysis. 5. Your comments on "Category 4 will be very small" and "category 2 is mechanically unavailable for challengers and open-seat candidates" is OK for me. 6. You can add the information on Committee stability you just found to the slide, which I think will be useful for my presentation. You should add a data source information as well because the presentation follows academic presentation standards. The trial_sample.tex is in \2026.07 AI - Political Donation Motive\AI Talk\Slide.

evidence, sourced to Stewart and Woon with the Dataverse DOI.

# On point 3 -- the search rule needs a date constraint

You asked me to flag anything that quietly relaxes the look-ahead rule. **This is the largest one yet**, and
it's worth settling before the first run.

If I search the open web today for a 2008 firm-candidate donation, the top results are: who won, what
committee they got in the 111th Congress, what legislation followed, and retrospective coverage of the
relationship. That isn't a subtle leak -- it's the most direct possible route to the answer, and it would
arrive precisely in the observations where I invoked search.

Which points at the real problem: **uncertainty-triggered search puts the most contaminated inputs into the
hardest cases.** The observations where the structured record is ambiguous are exactly the ones the outcome
analysis leans on, and they'd be the only ones informed by hindsight. That correlation is worse than uniform
contamination.

The fix isn't to ban search -- your instinct that the model shouldn't be boxed into the provided fields is
right, and it's what makes this more than a lookup table. It's to constrain the *vintage*:

- Search is permitted, but only sources **dated before that cycle's election date** may inform the
classification.
- Every source used gets logged with its date, in the output. This is cheap, it's verifiable, and it lands in
your AFA appendix as evidence of exactly the discipline a referee will ask about.
- Naturally admissible: Congressional Bioguide (biography, stable), the sitting Congress's committee roster,
```

pre-election news, the firm's last 10-K, DIME at t-1.

And one diagnostic worth building in from the start: **run a subsample both ways, with and without search**, and report how often the label changes. If search rarely moves the label, you've shown it isn't doing the leaking. If it moves it often, you need to know that before the outcome analysis, not after.

Unlike parametric leakage, this one is fully observable and controllable. Take the win.

On point 4 -- my recommendation differs for your two candidates

Add party/ideology. Don't add leadership. The reason is your own criterion: balance the number of categories against the distance between them.

Ideology is genuinely distant from all five. It's a different economic logic -- the firm gets utility from the candidate winning, not from access. Three arguments for including it:

It's the residual-absorber that shrinks "Others," which is what you want. Without it, every partisan donation with no district link, no committee link, and no social tie has nowhere to go but Others or category 3 -- which contaminates category 3 exactly where you want to read it as generic access.

More importantly, **it's the interpretive contrast the outcome analysis needs.** If you want to claim committee-motivated donations generate financial returns, you need a category where you predict they don't. Ideology is that category. Without it you have no internal benchmark, and the whole back half rests on cross-sectional comparisons with no null.

And it's measurable pre-election: t-1 CFscore, plus the firm's own giving pattern up to that point.

One design caution: define it as **evidence of alignment beyond mere co-partisanship** -- the firm's giving is strongly one-sided and this donation fits that pattern, with no firm-specific link to the candidate. Defined loosely as "same party," it becomes a second residual.

Leadership is not distant from committees -- it's an intensity dimension of the same access motive. A donation to the Ways and Means chair is a committee-motivated donation, only more so. Making it a sixth category would split category 2's mass and blur both. The exception is non-committee leadership (Speaker, whips), where the object is agenda control rather than jurisdiction -- but that's a small group.

So treat it the way you just decided to treat incumbent/contestant: **record it as a field, not a category.** You keep the information, you can interact it with whichever motive was assigned, and you can promote it to a category later at zero cost if it turns out to carry weight. You already have the raw material -- `house_powerful_cand_sample_1993_2022.dta` in your committee folder classifies 752 leadership and senior-party positions.

That lands you at six categories with two recorded fields:

	Category
1	Geography
2	Committee jurisdiction
3	Incumbent or contestant *(field: which)*
4	Social ties
5	Partisan/ideological alignment
6	Others *(field: different motive vs. insufficient information)*

I'd still record the Others split as a field even though you want both cases in one bucket -- it costs nothing and lets you check later whether Others is large because motives are missing from the taxonomy or because the record is too thin. Those imply different fixes.

Once you and your coauthor settle the priority order, the first run should test whether the model's labels beat the three mechanical indicators -- district match, `cand_ici`, and the GICS4-committee crosswalk. That's the gate.

--- AUTHOR [2026-07-28 01:45:34] --
1. We don't need to use "Can a Donor Forecast the Committee" as an action title because the information is based on committe membership stability. The footer position seems bit of wrong placed and should be closer to the left and right edge of the page, you can refer to G:\OneDrive - The Pennsylvania State University\PhD research projects\2024.12 Supply chain - politics\Slide\2025.11 PSU to figure out their supposed positions. You're free to choose a better title for the project and make the front page. The presenter is Stefan Lewellen and the presentation is for "Smeal COP in AI Research" (where COP stands for "COMMUNITY-OF-PRACTICE") for July 31, 2026. 2. I agree with your proposed vintage way of searching. Do we need to create a research or classification guidance for your exericse?

```
--- AGENT   [2026-07-28 01:46:36] ----------------------------------------
Both slide fixes plus a title frame. Let me match the reference deck's footer geometry:

--- AGENT   [2026-07-28 01:48:02] ----------------------------------------
Deck is now 5 pages, clean.

**Title frame** -- "Why Do Firms Give?" with "Inferring the Motives Behind Corporate Political Donations with
Large Language Models" as subtitle, Stefan Lewellen, Smeal Community-of-Practice in AI Research, July 31,
2026. Footer suppressed and the counter decremented on the title page, matching the PSU deck. The question
leads and the method follows -- though since this audience is there for the AI, the subtitle earns its place.
Tell me if the author line should list coauthors rather than just the presenter.

**Footer** -- the reference deck centers each half; I read your description as wanting the edges, so the
short title is now flush left and the counter flush right, both inset 0.80cm to line up with the text margin
`\geometry` sets. If you meant "match the reference exactly" rather than "push to the edges," say so and I'll
revert to centered halves.

**Frame 5** retitled to "Stability of House Committee Assignments" -- describes what's shown instead of
asserting the inference.

# On classification guidance: yes, and it's the gating document

Not optional. Three separate jobs make it necessary, and only one is about prompting.

**It is the instrument.** Six categories, a priority order, two recorded fields, a vintage rule, and edge
cases -- that's more than fits in a prompt written from memory each session. Written down, it's diffable:
version 3 of the guidance produced classification run 3, and when labels shift you can see which definition
moved.

**It is an AFA appendix artifact.** You need to submit the prompts anyway. A versioned `.md` in the repo
satisfies that automatically and demonstrates workflow design. This is also the concrete reason to move off
`Prompt Record.docx` -- a Word file gives you no diffs and no link between a prompt version and the run it
produced.

**It is what makes the vintage rule enforceable.** "Only sources dated before the election" has to be stated
somewhere the model reads every time, along with the explicit forbidden list: winner, vote share, subsequent
committee assignment, subsequent legislation.

What it should contain: the task and unit of observation; each category with its boundary against the
adjacent ones; the priority order; the output schema (chosen category, incumbent/contestant field, leadership
field, Others-type field, scores across all six, confidence, reasoning, and sources with dates); the vintage
rule and forbidden list; and edge cases -- refunds and negative amounts, multi-district HQs, category 2 being
unavailable for non-incumbents, missing GICS.

**One thing I'd add that isn't in your plan, and I think it matters more than the prompt itself: a hand-coded
validation set.**

If you and your coauthor each independently code the same 50 observations before any LLM run, you get two
things you cannot get later. Inter-coder agreement tells you whether the taxonomy is even well-defined -- if
two informed humans disagree on 40% of cases, the categories need work and no amount of prompt tuning will
fix it. And human-versus-LLM agreement is the only evidence that the labels are right.
```

A top-3 referee will ask how you know the classifications are correct. Absent a human benchmark, there is no answer. Fifty observations is perhaps two hours each, and it's the highest-value use of the next week -- it also gives your July 31 talk a real result rather than a pipeline description.

Want me to draft the guidance document? I'd write it as `Guidance/classification_protocol_v1.md` in the repo, and pair it with a 50-observation coding sheet drawn from the trial sample that you and Stefan can fill in independently.

--- AUTHOR [2026-07-28 02:00:10] ----------

I'm Ok to add a Add party/ideology category. My only question is whether you can sufficiently differentiate it from other categories, or you think our ordering rule can elimiate this issue? The gain will be a shurnk "Others" frequency, right? This is a good argurment " More importantly, it's the interpretive contrast the outcome analysis needs. If you want to claim
  committee-motivated donations generate financial returns, you need a category where you predict they don't. Ideology is that category. Without it you have no internal benchmark, and the whole back half rests on cross-sectional comparisons with no null.". In addition, do you think if we should have a md or record to show potential future readers our category decision process because I feel it's the key for this project. 2. Yes, I think the field for Committee jurisdiction can be "leadership" or not. 3. Does it mean there will be three columns/variables for you to fill: category, field (we can rename it with a better name), and reasoning (the reasoning part should be concise)? Maybe we can have source_x, where x is 1-5 in case you use other source or webaoge for the classification. I think we can determine the structure of the variables where you're going to fill in. After this and confirmation of categorical values, we can begin the first round exercise. 3. Yes, we plan to do one human classification assignment as well to confirm if the LLM classsifciation is correct or not. After we determine the categorical values and new fileds I will ask you to fill in, we will extract the first 200 observation with those fileds for the human assignment verification task.

--- AGENT [2026-07-28 02:01:31] ----------

1. Ideology: separable, but not by the ordering rule

Honest answer first: **the ordering rule does not solve this, and I'd be wary of relying on it.**

A priority rule works when the overlap is a minority of cases. Geography and committee genuinely conflict only occasionally -- a firm in the chairman's district -- so a rule picks a winner and little is distorted. Ideology versus category 3 is the opposite: **the overlap is most of the sample.** 90.5% of your observations are incumbents, and most corporate donations go to co-partisans. A firm giving to a co-partisan incumbent with no district or committee link fits both readings equally.

So whichever way you order 3 and 5, one category mechanically swallows the other, and the size of the ideology category gets set by convention rather than evidence. That's not differentiation -- it's a coin flip applied consistently.

What actually separates them is a variable you don't currently have. Three discriminators, all constructible pre-election:

- **The firm's own giving pattern at t-1.** An ideological giver is one-sided across many candidates. An access-motivated giver funds incumbents of both parties and tilts toward whoever holds the majority. Partisan concentration of the firm's prior-cycle dollars is the single best discriminator, and it's computable from the donation master you already have.
- **Candidate ideological extremity (t-1 CFscore).** Access money chases moderates and the powerful; ideological money tolerates extremists.
- **Giving to a challenger against a sitting incumbent.** Near-diagnostic -- you cannot buy access from someone who holds no seat.

Without at least the first of these, the model has only party label to work with, and category 5 will be weak no matter how the prompt is written. With it, the distinction becomes evidence-based and the ordering rule is relegated to genuine ties. I'd build the firm partisan-tilt variable before the first run; it's a few lines against the master.

On the gain -- I'd resist the framing. You asked whether the payoff is a smaller Others. Partly, but I can't promise that, and it may not be where the mass moves. Ideology could just as easily cannibalize category 3 rather than drain Others, since that's where the overlap lives. The benefit you quoted -- the null benchmark for the outcome analysis -- is the one I'd bank on, because it holds regardless of how the frequencies land.

Which suggests a cheap test worth building into round one: **classify the first batch twice, with and without category 5**, and watch what moves. If Others shrinks, you've confirmed your hypothesis. If category 3 shrinks instead, you've learned that generic access was absorbing ideology all along -- which is itself a finding about the taxonomy, and exactly the kind of thing that makes a measurement paper credible.

2. Yes -- and I'd argue it's more important than you're treating it

Your instinct is right, and I'd put it more strongly: for a paper whose contribution *is* a measurement, the taxonomy is the central research decision. A referee will ask why these six and not others. The difference between a taxonomy that reads as principled and one that reads as arbitrary is whether you can show the alternatives you considered and why you rejected them.

You already have real content for it: bill sponsorship considered and rejected (collapses into committee jurisdiction, and needs a firm-bill text-matching project to implement); leadership considered and demoted to a field (an intensity dimension of access, not a distinct motive); incumbent and contestant kept as one category with a field rather than split; committee data excluded, then reinstated lagged once persistence was measured. That last one is a good entry precisely because it records a reversal driven by evidence.

I'd write it as `Guidance/taxonomy_decisions.md`, append-only, one entry per decision: the question, options considered, what was chosen, why, what was rejected and why, who decided, and the date. It doubles as your AFA evidence of human research judgment -- this is exactly the artifact a discussant assessing "the nature of human labor" would want.

3. Output schema

One correction to your plan that saves effort: **don't ask the model for facts you can merge.** Incumbency is already in the sample (`cand_ici`); leadership merges from `house_powerful_cand_sample_1993_2022.dta` at t-1; committee jurisdiction merges from the t-1 assignments crossed with your GICS4 crosswalk. Asking the LLM for these wastes tokens and introduces error where you'd otherwise have certainty. Ask it only for judgments.

Proposed columns:

Column	Filled by	Notes
`gvkey`, `cand_id`, `cycle`	keys	
`motive`	LLM	the assigned category
`motive_2nd`	LLM	runner-up -- shows how close the call was, costs nothing
`confidence`	LLM	1-5
`reasoning`	LLM	<=2 sentences
`others_type`	LLM	when `motive` = Others: different motive vs. insufficient information
`search_used`	LLM	0/1 -- enables the with/without-search diagnostic
`source_1` ... `source_5`	LLM	format `description | URL | YYYY-MM-DD`, **date mandatory**
`cand_ici`, `cand_leadership_l1`, `cmte_jurisdiction_match_l1`	merged	facts, not judgments
`hq_st_match_cand`, `hq_cd_match_cand`	already built	

The mandatory date inside each source string is what makes the vintage rule auditable -- an undated source can't be checked, so it shouldn't be accepted.

The last three merged columns are also the mechanical indicators for the gate test: regress `motive` on them and see how much of the label is just a re-expression of what you already knew.

On leadership as a field of category 2 -- one refinement. Record `cand_leadership_l1` for *every* observation, not only where committee is the assigned motive. It costs nothing extra since it's merged, and it lets you ask whether leadership donations get classified as committee-motivated more often -- a question you can't answer if the field only exists conditional on the answer.

Say the word on the ideology discriminator and I'll build the firm partisan-tilt variable, then draft both documents -- `classification_protocol_v1.md` and `taxonomy_decisions.md` -- so the 200-observation extract for human coding has its final column structure.

--- AUTHOR [2026-07-28 02:47:20] ----------
1. I think I will try different sets of categorical values to find the best one, so the first attempt will not include category 5. I'll think about it after seeing the result. According, you can also write the taxonomy_decisions.md so that we have reference for our taxonomy. 2. I understand we want maximize the data I have and not waste the token. But do you think if I need to leverage LLMs to search for additonal information for this classification. Also, which BoardEx datasets do you need? Is it the Company Profile or Individual Profile? I can save the whole dataset in my drive (for future projects asw well), so you don't have to pull it. My question is whether you will need to access other data for our exercise? 2. Regarding the added column question, my question is what should be new columns added to random_1000_house_firm_cand_cycle_don_firm_info? You don't need to repeat columns that are already in the sample

--- AGENT [2026-07-28 02:48:21] ----------
Let me check one thing that bears on category 2 before answering -- whether your existing crosswalk covers the sample's industries.

```
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -c "

--- AGENT   [2026-07-28 02:51:48] ----------------------------------------
`Guidance/taxonomy_decisions.md` is written -- D1-D10 with the rejected alternatives, plus four open items.

## On Appropriations -- the data is fine, the mapping isn't

I checked both folders. The DIME Raw Data folder holds three files (the Bonica paper, an R script, and
`dime_recipients_1979_2024.csv.gz`) -- no committee data. But Appropriations membership is fully present in
Stewart & Woon: 895 member-Congress rows, 190 distinct members, every Congress.

So my gap was narrower than I made it sound. We know exactly who sat on Appropriations. What's missing is a
rule for **which firms should care** -- the GICS4 crosswalk maps industries to committees with subject-matter
jurisdiction, and appropriations exposure isn't industry-generic. Every industry could plausibly care, which
makes a universal link uninformative. Doing it properly means firm-level federal contract exposure from
USAspending/FPDS. For round 1 I'd let the model judge it and log the reasoning. Recorded as O2.

## Where search actually earns its place

| Category | Search needed? |
|---|---|
| 1 Geography | **No** -- `hq_cd_match_cand` is exact |
| 2 Committee | **Partly** -- the crosswalk is coarse: 11 committees, 1.6 per industry, no Appropriations, 2
unmapped codes |
| 3 Incumbent/contestant | **No** -- `cand_ici` is exact |
| 4 Social ties | **Yes, entirely** |
| Others | Yes, for adjudication |

Worth noticing what this implies: **categories 1 and 3 are pure lookups, so the LLM adds nothing there.** Its
value concentrates in category 2's firm-specific refinement (does this firm's actual business fall under this
committee, beyond what a GICS code implies?) and in category 4, which no structured file can answer. That's
also where the gate test will find whatever signal exists.

## BoardEx -- not either/or

You need Individual Profile *and* Company Profile, but for different jobs:

- **Individual profile** -- the biographical content. Essential.
- **Education** -- school, degree, year. This is the main tie channel and the one that actually matches.
- **Employment history / organization composition** -- tells you *who the firm's executives were in cycle t*.
Without the dated person-company link you can't say who was there at donation time.
- **Company profile + identifier mapping** -- the bridge from BoardEx company IDs to gvkey. Needed only for
merging.
- **Other activities** -- nonprofit boards, clubs. Optional, adds tie channels.

I'd want to confirm exact WRDS table names against the schema before you download, so let me do that when
you're ready rather than guess here.

Two cautions. BoardEx North America coverage begins around 1999-2000 and is thin early -- your sample starts
at cycle 2000, so the first few cycles will be sparse. And politicians have no identifier in common with
BoardEx individuals, so matching runs on name plus school plus year: low hit rate, high false-positive risk.
```

Which is why I'd not build the BoardEx pipeline for round 1. Let the model attempt category 4 by search across the trial 1,000 and measure how often it fires. If it fires on 1-2%, you've saved a week of matching work on an empty category. If it fires meaningfully, you'll know the pipeline is worth building and roughly what it has to hit. The only other source you'd need either way is the Congressional Bioguide for candidate biographies -- free, official, carries education and prior occupation.

New columns

Group A -- merged facts, built before classification (six new, plus one optional):

Column	Source
`cmte_l1`	t-1 committee list, readable
`cmte_jur_match_l1`	0/1, any t-1 committee with jurisdiction over the firm's GICS4
`cmte_jur_name_l1`	which committee(s) matched -- so a coder can see why
`cand_leadership_l1`	0/1, from `house_powerful_cand_sample_1993_2022.dta` at t-1
`cand_leadership_title_l1`	the position
`cand_tenure_l1`	Congresses served as of t-1 -- freshman vs veteran
`district_pres_vs` *(optional)*	district presidential vote share, pre-election competitiveness

Deliberately not adding t-1 CFscore in round 1. Ideology isn't in the taxonomy yet, and supplying an ideology variable would push the model toward a motive it has no category for -- contaminating exactly the round-1 result you want to read.

Group B -- blank columns for the model to fill: `motive`, `motive_2nd`, `confidence`, `reasoning`, `others_type`, `search_used`, `source_1`-`source_5` (each formatted `description | URL | YYYY-MM-DD`, date mandatory).

One methodological point about the 200-observation human task: the coding sheet must show Group A and blank Group B, with the LLM's labels held back until both are finished. If coders can see the model's answer, the benchmark measures agreement with an anchor rather than independent judgment, and it's worthless as validation.

Say the word and I'll build the Group A merges and produce both files -- the full 1,000 with blank output columns, and the blind 200-observation coding sheet.

--- AUTHOR [2026-07-28 03:11:36] ----------
1. Does taxonomy_decisions.md has too much information? I want it to be mainly for the taxonomy information so that readers can quickly understand our taxonomy, including different versions of taxonomy, with some major decisions? 2. Regarding committee assignment data, you can use any data in G:\OneDrive - The Pennsylvania State University\PhD research projects\1.Common Dataset\Politics\Committee Assignment. I think the reason my crosswalk file doesn't include Appropriations because Appropriation committee affects so many industries, which makes it difficult to merge with GICS. I checked 20171117_updated_house_cmte_assignments_103-115 and found it includes Appropriations. 3. You can look up BoardEx data on WRDS and save the pulled data in G:\OneDrive - The Pennsylvania State University\PhD research projects\1.Common Dataset\BoardEx\North America. Since I want to keep the data for future usage, can you also check the total size of Individual Profile and Company Profile data for BoardEx - North America, so that I can decide if we can pull all data once. Also tell me when does NA Individual Profile and Company Profile data starts. 4. As for the new columns, I don't think we need so many Group A columns. Our focus is the motive and all Group B variables (we can add one committee name as field variable, but considering some candidates may sit in several committee, we can have a field column that shows all committees a candidate sits in). We mentioned we want to have a separate field column for incumbent vs contestant and information for the other category. Why do your proposed Group B variables not have it? What's name of the field column, do we need more than one field column?

--- AGENT [2026-07-28 03:12:25] ----------
Let me start the WRDS lookup since that's the long pole -- a Duo prompt may hit your phone.
[action] Bash: export PGSERVICEFILE="$APPDATA/postgresql/pg_service.conf"; export

--- AGENT [2026-07-28 03:12:37] ----------
Connected. Now the North America tables with sizes:
[action] Bash: export PGSERVICEFILE="$APPDATA/postgresql/pg_service.conf"; export
↪ PGPASSFILE="$APPDATA/postgresql/pgpass.conf"; export PATH="$PATH:/c/Program Files/P

--- AGENT [2026-07-28 03:13:05] ----------
Sizes captured. Now column structure and date coverage on the tables that matter:
[action] Bash: export PGSERVICEFILE="$APPDATA/postgresql/pg_service.conf"; export
↪ PGPASSFILE="$APPDATA/postgresql/pgpass.conf"; export PATH="$PATH:/c/Program Files/P

```
      [action] Bash: export PGSERVICEFILE="$APPDATA/postgresql/pg_service.conf"; export
      ↪  PGPASSFILE="$APPDATA/postgresql/pgpass.conf"; export PATH="$PATH:/c/Program Files/P
      [action] Bash: export PGSERVICEFILE="$APPDATA/postgresql/pg_service.conf"; export
      ↪  PGPASSFILE="$APPDATA/postgresql/pgpass.conf"; export PATH="$PATH:/c/Program Files/P

--- AGENT   [2026-07-28 03:14:31] ----------------------------------------
Now the leaner decision file:
      [action] Write: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/Guidance/taxonomy_decisions.md
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && git add -A && git commit -q -F -

--- AGENT   [2026-07-28 03:15:54] ----------------------------------------
`taxonomy_decisions.md` is now 128 lines instead of 230 -- current taxonomy first, then version history, then
only the decisions that shaped the categories. Cutoff dates, search rules, and the output schema moved out to
belong in the protocol document.

## Committee data -- your read is right, and no new pull is needed

Appropriations affecting nearly every industry is exactly why a GICS mapping breaks down. Every industry has
some claim on appropriations, so a crosswalk link would fire universally and carry no information.

Worth clarifying one thing: the `.dta` I've been using (`house_standing_cmte_cand_candid_1993_2022.dta`)
already covers the 103rd-117th and **already contains Appropriations** -- 895 member-Congress rows across 190
members. The `20171117_updated` xls you checked is an older vintage of the same Stewart-Woon source, stopping
at the 115th. So membership is fully in hand; the only gap is the firm side, which the model will judge and
log.

## BoardEx North America

**Sizes** (Postgres on-disk, including indexes -- CSV export will differ, parquet would be perhaps a fifth):

| Bundle | Size | Key tables |
|---|---|---|
| **Individual / director profile** | **~12.1 GB** | `na_wrds_dir_profile_all` (5.5 GB, 17.2M rows),
`na_wrds_dir_profile_emp` (2.8 GB), `na_dir_profile_emp` (2.3 GB), `na_dir_profile_other_activ`,
`na_dir_characteristics`, `na_dir_profile_education`, `na_dir_profile_details`, `na_dir_profile_achievements`
|
| **Company profile** | **~0.9 GB** | `na_wrds_company_profile` (204 MB), `na_company_profile_details`,
`na_company_profile_sr_mgrs`, `na_wrds_company_names`, `na_wrds_company_region`, `na_company_profile_stocks` |
| **Person<->company links** | ~1.1 GB | `na_wrds_org_composition` (418 MB), `na_wrds_org_summary` (662 MB) |
| **Total worth pulling** | **~14 GB** | |

**Do not pull the network tables.** `na_wrds_individual_networks` alone is **437 GB** (1.58 billion rows),
and the four director-association tables add another 275 GB. The full schema is roughly 739 GB, so "all data
once" isn't feasible -- but the 14 GB that matters is entirely practical.

**When it starts.** Two different answers, and the distinction matters:

- **Individual profile** records career history *retrospectively*, so role start dates run back to 1900. But
the covered panel builds over time: role starts per year involve 6,653 firms in 1990, 16,254 in 1999, 18,008
in 2000, and 23,727 by 2007. Systematic North America coverage begins around **1999-2000** -- right at the
start of your sample, so the early cycles will be the thin ones.
- **Company profile is a snapshot, not a panel** -- it has no date column at all; it's current-as-of-vintage.
The historical company-level panel is `na_wrds_org_summary`, which carries `annualreportdate`.

For merging to your sample, `cikcode` appears in both `na_wrds_company_profile` and `na_wrds_org_summary` --
that's your bridge to Compustat via CIK, with `isin`/`ticker` in `na_company_profile_stocks` as a fallback.

Say the word and I'll pull the ~14 GB to `1.Common Dataset\BoardEx\North America` and add it to the data
catalog.

## Columns -- you're right that Group A was bloated

Cut to **one** merged column:

- **`cmte_l1`** -- every committee the candidate sits on in the sitting (t-1) Congress, comma-separated.

That single column also settles the leadership field, because Stewart-Woon codes leadership positions *as
committee rows* -- "speaker," "majority whip," "minority leader" all appear in `committeename`. So `cmte_l1`
```

carries membership and leadership together, unconditionally, for every observation. No separate leadership column needed.

On your question about the missing fields: incumbent-versus-contestant isn't in Group B because it's already in the sample as `cand_ici` -- it's a fact, not a judgment, so it needed no new column. And the Others type *was* in Group B as `others_type`; I'm now folding it into a single field, which answers your naming question.

One field column, `motive_detail`, with allowed values determined by the category:

`motive`	`motive_detail`
Geography	"HQ district" or "HQ state"
Committee	the committee name(s) that justify it
Incumbent or contestant	"incumbent" or "contestant"
Social ties	the tie channel -- e.g. "same university, overlapping years"
Others	"other: ?brief?" or "insufficient information"

One column rather than several, because the meaning is always recoverable from `motive`, it's always populated, and it keeps the human coding sheet narrow. Tabulating is just a filter on `motive` first.

So the full set of new columns: `cmte_l1`, then `motive`, `motive_detail`, `motive_2nd`, `confidence`, `reasoning`, `search_used`, `source_1`-`source_5`.

`motive_2nd` and `confidence` are optional but I'd keep both -- they cost nothing to produce and they're what lets you tell a confident classification from a coin flip when you compare against the human coding.

--- AUTHOR [2026-07-28 03:27:00] ----------
1. Why does taxonomy_decisions.md not include the 1st version of taxonomy we're going to use? I think it's the key for this file and don't think people are interested in add decision I made along the way? Also do we need to have a separate field for "leadership" or "powerful canddiates", which captures speaker and all powerful roles as I don't think most committee members are not decisive for a bill? 2. So I think na_wrds_org_summary is key to have as we do need annual snap short to determine the executives of a firm before the election dates to assign the social tie category. 3. What information do you plan to fill in motive_detail?
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && head -30 Guidance/taxonomy_decisi

--- AGENT [2026-07-28 03:27:32] ----------
v1 is at the top of the file (lines 11-23) -- your editor may be showing the pre-rewrite version; reopen it. But I'll take the point about proportion and cut the decisions down further.

Let me check how your existing powerful-candidate file defines power:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common Dataset/Politics/Committee Assignment" && python -c " import pandas
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common Dataset/Politics/Committee Assignment/103rd_115th_standing_cmte_ass
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common Dataset/Politics/Committee Assignment/103rd_115th_standing_cmte_ass

--- AGENT [2026-07-28 03:28:37] ----------
The codebook gives exact definitions. Let me verify how your derived file uses them:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common Dataset/Politics/Committee Assignment" && python -c " import pandas

--- AGENT [2026-07-28 03:29:40] ----------
Now I have the exact definitions, and one finding worth flagging.

Your `powerful` file is `seniorpartymember != 0` -- 752 of 798 rows match exactly. By the Stewart-Woon codebook that means: committee chairs (354), ranking minority members (323), Speaker (12), Majority/Minority Leader (24), Majority/Minority Whip (25), vice/co-chairs (9).

But the derived `seniority` variable in that `.dta` is not what the codebook describes. The codebook defines committee seniority as the term count on the committee (1, 2, 3...); your file has it as 0/1 with 1,466 ones -- a superset of `seniorpartymember != 0`. I don't know what the extra 668 rows are, so I'd build the power field from `seniorpartymember`, which has an unambiguous codebook definition, and leave `seniority` alone.
[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance/taxonomy_decisions.md

```
    [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
    ↪  Political Donation Motive" && python - <<'PY' import io, re p =
    [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
    ↪  Political Donation Motive" && sed -i 's/| v1 | 2026-07-27 | Fiv

--- AGENT   [2026-07-28 03:30:52] ----------------------------------------
**On the file:** v1 was already there -- lines 11-23, the five-category table with the priority order. Your
editor was showing the pre-rewrite version. But the proportion point was right: decisions are now short
notes, and the file opens with the taxonomy and its fields. 105 lines.

## Power field -- agreed, and it's a better argument than mine

You're right that committee membership is a weak proxy for influence. A rank-and-file member of Energy and
Commerce and its chair are not the same donation target, and my "`cmte_l1` already carries leadership" answer
only covered floor leadership (Speaker, whips appear as committee rows) -- it missed **chairs and ranking
members entirely**, which are the bulk of what matters. 354 chairs and 323 ranking members versus 61 floor
leaders in your file.

So `cand_power_l1` is now a separate merged field, built from `seniorpartymember` per the codebook. About
5.8% of member-committee-Congress rows qualify.

## `na_wrds_org_summary` -- include it, but it isn't the timing tool

Your reasoning is right that you need to know who the executives were *before* the election. But
`org_summary` is keyed on `annualreportdate` -- a fiscal-year snapshot. **`na_wrds_org_composition` is the
better instrument for the cutoff**, because it carries `datestartrole` and `dateendrole` explicitly, so you
can ask exactly who held a role on any given date rather than inferring from the nearest annual snapshot.

I'd pull both (418 MB + 662 MB): `org_composition` for the pre-election executive roster, `org_summary` for
annual board composition, compensation, and the `cikcode` bridge to Compustat. One caution -- `dateendrole`
is likely null or sentinel for ongoing roles, so the "still there at date X" test needs care.

## What goes in `motive_detail`

Format: name the specific entity, keep it under about ten words, and never assert anything not supported by a
logged source.

| `motive` | Content | Example |
|---|---|---|
| Geography | which level matched, with the district | `HQ district NV-01` . `HQ state NV, no district match`
|
| Committee | the committee driving it, plus the candidate's role there | `ways and means (chair)` . `energy
and commerce (member)` |
| Incumbent/contestant | which, plus what makes the seat valuable | `incumbent` . `contestant, open seat` |
| Social ties | the channel and the person | `education: same law school, overlapping years` . `board
overlap: J. Smith, 1998-2003` |
| Others | the alternative motive, or why undetermined | `other: trade association coordination` .
`insufficient information: no executive roster for 2000` |

For a verified example from the sample: MGM Resorts -> Shelley Berkley, 2008 cycle, HQ in NV-01 and NV-03,
candidate contesting NV-01 -- `motive` = Geography, `motive_detail` = `HQ district NV-01`.

Note the committee entry duplicates information in `cand_power_l1`. That's deliberate: the merged field
records what was *true*, `motive_detail` records what the model *used*. When they disagree, that's diagnostic.

Final new-column set: `cmte_l1`, `cand_power_l1`, then `motive`, `motive_detail`, `motive_2nd`, `confidence`,
`reasoning`, `search_used`, `source_1`-`source_5`.

Ready to build the two merged columns and produce both files -- the 1,000-row sheet with blank output
columns, and the blind 200-row human coding sheet -- whenever you confirm the priority order (O1).

--- AUTHOR  [2026-07-28 03:41:58] ----------------------------------------
1. You can pull the whole whole Individual / director profile and na_wrds_org_summary data (I mean both (418
MB + 662 MB)) and save them in my drive, so that we can use them for furture analysis as well. 2. Now I
understand what motive_detail wants to capture and agree to have it. One note about cand_power_l1: if a
candidate sits in multiple committees and a powerful candidate for any comittee, cand_power_l1 should be 1,
right? 3. Do we also need to have a classification and search guidance for LLM so that the exercise is
largely reproducible?

--- AGENT   [2026-07-28 03:44:13] ----------------------------------------
**BoardEx pull is running in the background** -- 10 tables to `1.Common Dataset\BoardEx\North America`,
gzipped, smallest first so failures surface early. First table is already down. It's resumable, so if it dies
partway a rerun picks up where it left off, and progress is in `_pull_log.txt`. I'll report when it finishes.

Two notes: I'm pulling the individual/director bundle plus `org_composition` and `org_summary` as you
specified, **not** the company-profile bundle. `org_summary` carries `cikcode`, so the Compustat bridge is
covered; the company tables are only ~0.9 GB if you want them later. Also, OneDrive will try to sync ~13 GB
of new files -- you may want to pause sync while it runs.

## `cand_power_l1` -- yes, with one loss worth avoiding

Your definition is right: 1 if the candidate holds a senior-party position on **any** committee.

But a bare flag conflates two different things, and members sit on **2.05 committees on average**, so the
conflation bites. A pharmaceutical firm cares that the candidate chairs Energy and Commerce. It does not care
that the candidate chairs Veterans Affairs. Collapsed to 0/1, those look identical -- and category 2 is
precisely about the committee *with jurisdiction over this firm*.

Cheap fix, no extra column: **annotate `cmte_l1` with the role**.

```
cmte_l1        = "ways and means (chair), budget (member)"
cand_power_l1  = 1
```

The flag stays for easy filtering, and the mapping from power to committee survives -- so "powerful on the
committee that matters to this firm" stays derivable by crossing `cmte_l1` with the GICS4 crosswalk, without
another column.

Guidance document -- yes, and reproducibility needs more than a prompt

That's the `classification_protocol.md` I've been referencing. It should carry: the task and unit of
observation; each category's boundary against its neighbours; the priority order; the output schema with
allowed values; the vintage rule and the forbidden list; the search protocol; edge cases; and a few worked
examples.

But I want to be straight about the word *reproducible*, because it's where this design is most exposed to a
referee.

An LLM classification is not deterministic, and a fixed prompt does not make it so. Model versions change
under the same name, search results differ by the day you run them, and sampling varies run to run. If the
paper claims reproducibility on the strength of a documented prompt, that claim will not survive scrutiny.

What you can honestly claim is documented conditions plus measured instability. So the protocol should also
fix:

- **Model ID and version recorded per run**, not just "Claude" or "GPT."
- **Temperature 0**, and the date of the run -- because search results are time-varying, the run date is part
of the method.
- **A rerun-stability check**: reclassify a random 100 observations a second time and report the agreement
```

rate. If the model disagrees with itself 15% of the time, that's a ceiling on any accuracy claim, and you want to know it before the human coding rather than after.

That stability number pairs naturally with the inter-coder agreement from your 200-observation human task. Together they tell you how much of the disagreement between human and model is genuine disagreement versus noise on either side -- which is the question a referee will actually ask.

Want me to draft `classification_protocol.md` now? It's the last piece before the merged columns and the two output files, and the priority order (O1) is the only input I'm still missing.

--- AUTHOR [2026-07-28 03:51:49] ----------

1. I love your cheap fix! Let's adopt it. 2. I think it better to put classification_protocol.md also in the Guidance folder so that the folder contains all important guidance files. I understand "An LLM classification is not deterministic, and a fixed prompt does not make it so" and this is OK. I simply want the guidance to guard the LLM classification and search behaviour (in a way, it's like a prompt the LLM will use) so that most classifications are correct. We can also record the model version and date of the classification to make readers know the classificaiton results are indeed what we got from an LLM. To make this happen, I think we can rename the input csv by adding "date_LLM_model" after its original name, so it also will be easifer for me to track the version. We can make the current output files saved in \2026.07 AI - Political Donation Motive\AI Talk.

[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common Dataset/BoardEx/North America" && tail -6 _pull_log.txt; echo "---

--- AGENT [2026-07-28 03:52:41] ----------

7 of 10 tables down. Election dates computed. Writing the protocol -- but one thing in it needs your attention first, so let me flag it before the file.

The priority order 1->2->3->4->5 would make social ties impossible to record. Category 3 as written ("holding a seat and able to act now, or seeking one") is true of *every* candidate by definition -- they are all either incumbents or contestants. So under strict priority, category 3 absorbs everything that isn't geography or committee, and categories 4 and 5 can never fire.

The fix is to order most-specific-first: **firm-relational categories before candidate-only ones.** Geography, committee, and social ties all describe a link between *this firm* and *this candidate*. Incumbent-or-contestant describes the candidate alone. So:

1 Geography -> 2 Committee -> 4 Social ties -> 3 Incumbent/contestant -> 5 Others

That makes category 3 the explicit default before Others, which matches what it actually means -- generic access.

[action] Write: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance/classification_protocol.md

[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && git add -A && git commit -q -F -

--- AGENT [2026-07-28 03:54:01] ----------

`Guidance/classification_protocol.md` is written -- both guidance files now live together.

On reproducibility, we're aligned. Your framing is the right one: the protocol's job is to *guard* classification and search behaviour so most labels are correct, and to record model and date so readers know what produced them. The protocol does both. My earlier point stands only as a caution against *claiming* determinism in the paper -- the run metadata and the stability check are what let you make the honest version of the claim instead.

File naming, as you specified:

```
AI Talk/random_1000_house_firm_cand_cycle_don_firm_info_20260728_claude-opus-5.csv
```

with a companion `_runlog.md` entry recording exact model version, temperature 0, run date, protocol version, and any deviation.

What's in the protocol

The parts doing real work:

The information rule carries the twelve election dates explicitly, so there's no per-observation date arithmetic to get wrong. It also names the failure mode directly: *"You will often know these things. Knowing them is not a licence to use them."* And it bars reasoning backwards from outcomes -- "this member later

chaired the committee, so the firm must have anticipated it" is the exact error to prevent.

The search protocol has one subtlety worth your eye. Stable biographical facts are exempt from the date test but not from logging: a present-day Bioguide page documenting a 1978 law degree is admissible, because the degree didn't change. A present-day page describing the same person's legislative record is not. Without that carve-out, category 4 would be nearly impossible to establish, since biographical sources are mostly current-vintage.

Category boundaries rather than definitions, since that's where classification actually goes wrong -- geography is about *where the candidate runs*, committee about *what they have authority over*; a candidate on three committees, none touching this firm, is not category 2; a social tie must be specific and named, so "both went to law school" fails and "both took JDs at Virginia, overlapping 1979-81" passes.

A standing instruction not to force a guess to keep Others small. A forced label becomes indistinguishable from a confident one, which is exactly what would corrupt the human validation.

Still open

The priority order is the one input I need before building the files. The protocol uses **1 -> 2 -> 4 -> 3 -> 5** for the reason above, marked pending your confirmation. If you and Stefan prefer strict numeric order, category 4 needs redefining as something other than a competing category -- otherwise it will be empty by construction.

BoardEx is on the second-to-last table, `na_wrds_dir_profile_emp`. Seven done, compressing far better than expected -- `org_summary` came down to 57 MB from 662 MB on disk. I'll report the totals when it finishes.

--- AUTHOR [2026-07-28 04:03:45] ----------
1. In the table of categorical values, I also want to have a column showing whether that categorgy needs online search or not, so that I can better track what LLMs do for that version of taxonomy. 2. I agree with your File naming and _runlog.md suggestion, let's do it this way. 3. Let's extract the first 200 observations from random_1000_house_firm_cand_cycle_don_firm_info and add the columns the LLMs will add to the saved copy so that human verification work can be done. 4. I think 1 -> 2 -> 4 -> 3 -> 5 is the correct prioroty order and we should have it clear in the classification_protocol.md and taxonomy_decisions.md for this version exercise. Let's call this version v1, create a section for v1 in taxonomy_decisions.md, and rename classification_protocol.md as classification_protocol_v1.md. We may later do v2. The taxonomy information will appear in taxonomy_decisions.md but the prompt will be classification_protocol_v2.md. Do think if this is a good practice? Is it better to call classification_protocol as classification_prompt?

--- AGENT   [2026-07-28 04:09:04] ----------------------------------------
All four done.

## BoardEx -- complete

All 10 tables, zero failures, **1.9 GB gzipped** from ~13 GB on disk, in `1.Common Dataset\BoardEx\North
America`. Largest is `na_wrds_dir_profile_all` at 666 MB; `na_wrds_org_composition` (your pre-election
executive roster) is 52 MB. Worth adding to `DATA_CATALOG.md` when convenient.

## Files built

`AI Talk/random_1000_house_firm_cand_cycle_don_firm_info_for_classification.csv` -- 1,000 rows, 42 columns
`AI Talk/human_coding_first200_blind.csv` -- first 200, same structure, all 11 classifier columns verified
empty

`cmte_l1` is populated for 89.6% overall and **98.8% of incumbents**, with power roles sorted first: `ways
and means (ranking minority), taxation (joint) (member)`. Chamber leadership renders without redundant
annotation -- `majority whip, appropriations (member)`. `cand_power_l1` fires on 14.0%.

## Naming -- I'd go further than you suggested

You asked whether `classification_prompt` beats `classification_protocol`. **Prompt is the better name, and
I've made the change** -- but the honest version required a split, so I did that too.

The old file mixed two audiences: rules the model reads, and procedure you follow (file naming, run metadata,
quality checks). For the AFA appendix you need the prompt quotable *verbatim* -- mixing in researcher
procedure means explaining what was and wasn't sent. So:

- `classification_prompt_v1.md` -- only what the model receives. Versioned with the taxonomy.
- `run_procedure.md` -- file naming, run metadata, quality checks. Version-independent, so no suffix.

Your scheme is otherwise good practice. One refinement: if you revise prompt wording without changing
categories, use `v1.1` rather than `v2` -- the version number should track the taxonomy it implements, and
the runlog records both.

The taxonomy table now carries your **"Needs online search?"** column: no for geography and incumbency,
always for social ties, sometimes for committee (appropriations and the two unmapped GICS codes) and Others.

## One problem with the first 200

They cover **only cycles 2000, 2002, and 2004** -- three of twelve, because the sample sorts by cycle. Your
validation set would be entirely pre-2005.

That matters here more than usual. BoardEx coverage is thinnest in exactly those years, so category 4 will be
least detectable in the validation sample and most detectable everywhere else. Committee composition and
party control also shift over the period. Agreement measured on 2000-2004 won't transfer to 2012-2022.
```

A random 200, or 17 per cycle stratified, would cost one line in the do-file. Say the word and I'll regenerate -- the file is cheap to rebuild, and it's better fixed before anyone starts coding than after.

--- AUTHOR [2026-07-28 04:18:27] ----------
1. I feel the current file name is too long. I want to rename random_1000_house_firm_cand_cycle_don_firm_info as random_1000_house_firm_cand_cycle_don. Please update other file names accordingly. Also since we will do only the classification exercise for the csv file, you don't need to create the dta file for now. 2. Regarding the committee classification, we have data in G:\OneDrive - The Pennsylvania State University\PhD research projects\1.Common Dataset\Politics\Committee Assignment\103rd_115th_standing_cmte_assign. Do you still need to search online? I understand we "always" need to search for the Social ties category even if we have BoardEx because I don't have background information for candidates. Is this understanding correct?
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/AI Talk" && ls *.dta *.csv 2>/dev/nul

--- AGENT [2026-07-28 04:19:27] ----------
The human-coding file is already renamed to your convention and the classification `.dta` files are gone -- I'll follow that pattern.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && git status --short && echo "--- r

--- AGENT [2026-07-28 04:19:39] ----------
Now updating both do-files to match:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/AI Talk" && python - <<'PY' import io

--- AGENT [2026-07-28 04:20:07] ----------
My Python edit mangled paths -- `\r` in the replacement string became a carriage return. Fixing directly:
[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/AI Talk/2.add_committee_fields_and_classi
[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/AI Talk/2.add_committee_fields_and_classi
[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/AI Talk/2.add_committee_fields_and_classi
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/AI Talk" && sed -n '125,140p' 2.add_c

--- AGENT [2026-07-28 04:20:30] ----------
Confirmed -- a literal `^M` (CR) is embedded. Replacing it at the byte level:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/AI Talk" && python -c " import io p='

--- AGENT [2026-07-28 04:20:43] ----------
The do-file is clean now. Rerunning to regenerate under the new names:
[action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research ↪ projects\2026.07 AI - Political Donation Motive\AI Talk"; $p = Start-Proces

--- AGENT [2026-07-28 04:20:55] ----------
Now updating the guidance files' filename references and sharpening the committee search wording:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/Guidance" && python -c " import io p=
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && git add -A && git commit -q -F -

--- AGENT [2026-07-28 04:21:35] ----------
Renames done, CSV only for the classification files, both scripts and the guidance updated.

Committee -- you're right, and I'd been imprecise

No, search isn't needed for committee membership. The `103rd_115th_standing_cmte_assign` folder is the same Stewart-Woon source as the `.dta` I'm using -- which is actually the newer vintage, covering the 103rd-117th rather than stopping at the 115th. Membership is fully in hand and already sits in `cmte_l1`, populated for 98.8% of incumbents.

The "sometimes" was about a different question that I'd conflated with membership: **does this committee's jurisdiction cover *this firm*?** That's the firm side, and it rests on the GICS4 crosswalk, which covers 24 of 26 industries in the sample. Search can be needed for three narrow cases -- appropriations exposure (no crosswalk entry exists, by design), the two unmapped GICS4 codes (31 observations), and diversified firms whose GICS code is too coarse to describe what they actually do.

```
I've rewritten that table cell to separate the two: *"Not for membership -- `cmte_l1` supplies it in full.
Sometimes for jurisdiction..."*

## Social ties -- your understanding is exactly right

BoardEx gives the **firm** half: executives, their education, prior employers, affiliations. There is no
candidate-side background data anywhere in the project. A tie needs both halves, so candidate biographies
must come from search -- Congressional Bioguide being the natural source. Hence "always."

**One practical gap you should know about before round 1.** The classification file currently contains *no
firm-executive information at all* -- BoardEx is downloaded but nothing from it is merged in. So as things
stand the model would have to search for both halves of the tie, not just the candidate half. That will
produce weak and inconsistent results for category 4, which is the category you most want to learn about.

The fix is a compact companion file: `gvkey x cycle -> senior executives as of the pre-election date, with
education and prior employers`, built from `na_wrds_org_composition` (role start and end dates give you the
exact roster before the cutoff) joined to the education and employment tables. The model consults it rather
than guessing who ran the firm in 2004.

That's a real piece of work -- a few hours, and it needs the BoardEx-to-gvkey link via `cikcode` -- so I'd
rather you decide than have me start it. Without it, expect category 4 to be near-empty for reasons that have
nothing to do with whether social ties actually matter.

--- AUTHOR  [2026-07-28 04:34:44] ----------------------------------------
1. I forget we need to save the whole BoardEx-to-gvkey link as well, otherwise the BoardEx data is not
useful, so let's do it now. 2. I don't to waste token, so let's also create a
random_1000_house_firm_cand_cycle_don_first200_for_llm.csv, which we can first to determine if the results go
as the way we expect. It won't be a waste of token as if the classification looks good, we can directly copy
and paste the classification results of the first 200 observations to
random_1000_house_firm_cand_cycle_don_firm_20260728_claude-opus-5.csv. 3. I like the idea of having a compact
companion file: gvkey x cycle -> senior executives as of the pre-election date, with education and prior
employers, which is built from na_wrds_org_composition. Do you think if we need to record this fix in the
beginning of the taxonomy_decisions.md and make classification_prompt_v1.md refer to the output files?
      [action] Bash: export PGSERVICEFILE="$APPDATA/postgresql/pg_service.conf"; export
      ↪  PGPASSFILE="$APPDATA/postgresql/pgpass.conf"; export PATH="$PATH:/c/Program Files/P

--- AGENT   [2026-07-28 04:35:30] ----------------------------------------
`wrdsapps_link_crsp_comp_bdx.bdxcrspcomplink` is the one. Checking its structure:
      [action] Bash: export PGSERVICEFILE="$APPDATA/postgresql/pg_service.conf"; export
      ↪  PGPASSFILE="$APPDATA/postgresql/pgpass.conf"; export PATH="$PATH:/c/Program Files/P

--- AGENT   [2026-07-28 04:35:46] ----------------------------------------
Both link tables are small. Pulling them plus checking coverage against your sample:
      [action] Bash: export PGSERVICEFILE="$APPDATA/postgresql/pg_service.conf"; export
      ↪  PGPASSFILE="$APPDATA/postgresql/pgpass.conf"; export PATH="$PATH:/c/Program Files/P
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -c "
      ↪  import pandas as pd D='1.Common Dataset/BoardEx/North Americ

--- AGENT   [2026-07-28 04:36:25] ----------------------------------------
97.6% of sample observations map to a BoardEx company -- better than I expected, and even cycle 2000 hits
85.6%. Both link tables saved. Now the LLM pilot file:
      [action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk/2.add_committee_fields_and_classi
      [action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research
      ↪  projects\2026.07 AI - Political Donation Motive\AI Talk"; $p = Start-Proces

--- AGENT   [2026-07-28 04:36:44] ----------------------------------------
Now the guidance updates -- an Inputs section in the prompt, and the category-4 search cell:
      [action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/Guidance/classification_prompt_v1.md
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/Guidance" && python -c " import io p=
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && git add -A && git commit -q -F -

--- AGENT   [2026-07-28 04:37:37] ----------------------------------------
All three done.

## BoardEx links -- and you were right that this was the missing piece
```

Two tables saved to `1.Common Dataset\BoardEx\North America`:

- `link_boardex_crsp_compustat.csv` -- 12,561 rows, company-level `gvkey <-> companyid` with match scores
- `link_execucomp_boardex_people.csv` -- 68,723 rows, person-level `execid <-> directorid`

Coverage against your sample is strong: 582 of 599 firms (97.2%), 976 of 1,000 observations (97.6%). Cycle 2000 is the weakest at 85.6%, climbing to 100% from 2018. Better than the early-coverage caution I gave you earlier -- the company link is fuller than the role data will be.

Pilot file

`random_1000_house_firm_cand_cycle_don_first200_for_llm.csv` -- the **same 200 rows** as the human-coding sheet, so the two are comparable observation by observation, shipped as a separate file so model output never touches the human sheet. Both regenerate from the do-file.

One small correction to the name you wrote: the convention drops the stray `firm`, so the run output is `random_1000_house_firm_cand_cycle_don_20260728_claude-opus-5.csv`.

On where to record it -- I'd split your suggestion

Yes to the prompt referring to the files. That was a genuine gap: the prompt described columns but never named the files it operates on. It now opens with an Inputs table listing the full run file, the pilot, and the `exec_roster_l1` companion -- with the companion marked *not yet built*, and a note that until it exists the model must search for the firm's executives too. The model should know what it doesn't have.

No to putting it at the top of `taxonomy_decisions.md`. That file just went from 230 lines to 105 by removing exactly this kind of operational content, and an input-file inventory would start it growing again. Data inputs also change independently of the taxonomy -- you could rebuild the roster three times without touching a single category.

What *does* belong there is the one-cell consequence for category 4, which I've made: its search entry now reads that BoardEx supplies the firm half and only the candidate half must be searched. That's a fact about the taxonomy's feasibility, not about plumbing.

The division that keeps working: **taxonomy file = what the categories are; prompt = what the model reads and how it decides; run procedure = how a run is executed and checked.**

Ready when you are

The `exec_roster_l1` companion is the last unbuilt piece. Now that the gvkey link exists, it's a join from `na_wrds_org_composition` (role start/end dates give the exact pre-election roster) to the education and employment tables, filtered to your 599 firms. Say go and I'll build it -- otherwise the pilot can run without it, and category 4 will simply be weaker than it needs to be.

--- AUTHOR [2026-07-28 04:44:40] ----------
1. Let's create the full BoardEx-to-gvkey till the end of 2025 (if the matching is at the annual level) or 2026 H1 (if the matching is at the quarterly) via cikcode since I may also need it for future projects if the current files only cover the crosswalk after 2000. 2. I agree with your argument on "split my suggestion". Let's fix these issues for this run. Then we will do our first classification attempt in the next run. I also want to confirm whether we have created the compact companion file gvkey x cycle -> senior executives as of the pre-election date, with education and prior employers, which is built from na_wrds_org_composition (role start and end dates give you the exact roster before the cutoff). If not, I assume it should be the first work we need to do before the real first classification attempt?

--- AGENT [2026-07-28 04:45:05] ----------
Let me check something first, because it changes what you're asking for.
[action] Bash: export PGSERVICEFILE="$APPDATA/postgresql/pg_service.conf"; export
↪ PGPASSFILE="$APPDATA/postgresql/pgpass.conf"; export PATH="$PATH:/c/Program Files/P
[action] Bash: export PGSERVICEFILE="$APPDATA/postgresql/pg_service.conf"; export
↪ PGPASSFILE="$APPDATA/postgresql/pgpass.conf"; export PATH="$PATH:/c/Program Files/P

--- AGENT [2026-07-28 04:45:45] ----------
The CIK route finds **13,702 gvkeys versus 11,687** from the WRDS link -- worth having. Let me verify the identifiers align and build a combined link:
[action] Bash: export PGSERVICEFILE="$APPDATA/postgresql/pg_service.conf"; export
↪ PGPASSFILE="$APPDATA/postgresql/pgpass.conf"; export PATH="$PATH:/c/Program Files/P

--- AGENT [2026-07-28 04:46:11] ----------
Confirmed `boardid` = `companyid`. Building the combined link:

```
      [action] Bash: export PGSERVICEFILE="$APPDATA/postgresql/pg_service.conf"; export
      ↪  PGPASSFILE="$APPDATA/postgresql/pgpass.conf"; export PATH="$PATH:/c/Program Files/P
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -c "
      ↪  import pandas as pd D='1.Common Dataset/BoardEx/North Americ
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && git add -A && git commit -q -m "$

--- AGENT   [2026-07-28 04:47:12] ----------------------------------------
The link files live in `1.Common Dataset`, outside this project's repo -- nothing to commit there, which is
correct. Let me update the shared catalog instead, since the convention requires it:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
      ↪  Dataset" && wc -l DATA_CATALOG.md && grep -n "^#\|^##" DATA_CATALOG
      [action] Read: G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
      ↪  Dataset/DATA_CATALOG.md
      [action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
      ↪  Dataset/DATA_CATALOG.md

--- AGENT   [2026-07-28 04:47:51] ----------------------------------------
Done. Catalog updated too.

## The link has no time dimension

Worth correcting the premise behind your request: **`bdxcrspcomplink` is a static crosswalk** -- its columns
are `permco, gvkey, companyid, score, preferred, duplicate`. No dates. Same for the CIK route. So there's no
annual or quarterly vintage to extend "through 2025 or 2026 H1" -- coverage is a function of the underlying
WRDS table vintage, which is July 2026, not of a year range. The 2000-onward concern doesn't apply.

I built the CIK link anyway, because your other reason was sound:

| | gvkeys |
|---|---|
| WRDS `bdxcrspcomplink` alone | 11,687 |
| **Combined (WRDS ? CIK)** | **14,534** |

11,504 pairs agree across both routes; 3,768 come only from CIK; 1,015 only from the WRDS link. Source flags
`via_wrds_link` and `via_cik` are kept so you can restrict to either.

**For this project it adds nothing** -- both routes give 582 of 599 firms. The gain is entirely for future
projects, which is what you asked for. Saved as `link_boardex_gvkey_combined.csv`, and both BoardEx rows are
now in `DATA_CATALOG.md`.

## `exec_roster_l1` -- not created, and yes, it goes first

Confirmed: it does not exist. The prompt's Inputs section lists it as *not yet built*.

And your instinct about ordering is right, for a reason drawn from your own plan rather than from principle.
You said the pilot's purpose is to check the results look good and then **paste those 200 classifications
straight into the full file**. That makes the pilot output something you intend to keep. If category 4 is
structurally unable to fire during the pilot -- because the model has no idea who ran the firm in 2004 --
then those 200 rows carry a category that was never really tested, and you'd have to redo them once the
roster exists.

A pilot you plan to discard could run without it. A pilot you plan to keep cannot.

So the order is: build `exec_roster_l1` -> run the 200-row pilot -> inspect -> paste into the full file ->
run the remaining 800.

The build is now unblocked, since the gvkey link exists. It's a join from `na_wrds_org_composition` (role
start/end dates give the exact roster before each cycle's cutoff) to education and prior employment, filtered
to your 599 firms, keyed `gvkey x cycle`. The main judgment call is how many executives to include per
firm-cycle -- all directors and officers would be 10-20 people, which is a lot of text per row; the top 5-8
by seniority is probably the right compromise.

Ready to build it whenever you say go.

--- AUTHOR  [2026-07-28 04:47:52] ----------------------------------------
Also I want you to save the code to create BoardEx-to-gvkey crosswalk file so that the crosswalk file can be
reproducible
```

--- AGENT [2026-07-28 04:48:06] ----------
Right -- that was run inline, which makes it unreproducible. Saving it as a script:
[action] Write: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/scripts/build_boardex_gvkey_link.sh

--- AGENT [2026-07-28 04:48:31] ----------
Now let me verify it actually reproduces the same output -- that's the real test:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && bash scripts/build_boardex_gvkey_

--- AGENT [2026-07-28 04:48:54] ----------
All three counts reproduce exactly -- 12,561 / 68,723 / 16,287. Adding the pointer to the catalog:
[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common Dataset/DATA_CATALOG.md
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && git add -A && git commit -q -F -

--- AGENT [2026-07-28 04:49:25] ----------
`scripts/build_boardex_gvkey_link.sh` -- and I ran it end to end rather than just saving what I'd typed, so it's verified rather than assumed: **12,561 / 68,723 / 16,287 rows, matching the original exactly.**

The script carries three things worth having beyond the SQL:

The expected row counts are in the header comment, so a future rerun can be checked against them rather than trusted. If WRDS revises the underlying tables, the mismatch will be visible immediately instead of silently propagating.

The `boardid == companyid` finding is recorded, with the verification (14,389 of 14,405 join rows). That equivalence isn't documented anywhere obvious in the WRDS schema, and it's the join that makes route B possible.

The static-vintage warning is in the file itself, not just in my message to you -- so whoever picks this up in 2028 doesn't repeat the question about extending coverage through a year range. The instruction is to record the pull date, since that's the only vintage the crosswalk has.

`DATA_CATALOG.md` now points at both scripts from the BoardEx rows, so a future project finds the build code from the data rather than having to know this project exists.

Two scripts now cover the whole BoardEx acquisition:

Script	Produces
`scripts/pull_boardex_na.sh`	The 10 BoardEx NA tables, 1.9 GB gzipped
`scripts/build_boardex_gvkey_link.sh`	The three crosswalk files

Both are resumable or idempotent, so rerunning is safe.

Next is `exec_roster_l1` -- the `gvkey x cycle` senior-executive roster with education and prior employers, which is the last piece before the 200-row pilot. Say go and I'll build it as a third script in the same pattern.

--- AUTHOR [2026-07-28 04:49:29] ----------
You can save the code to create the crosswalk file in \1.Common Dataset\BoardEx because it's not only for the AI - Political Donation Motive project.

--- AGENT [2026-07-28 04:49:46] ----------
Fair -- they're shared-asset builders, not project code. Same logic applies to the table pull, so I'll move both:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && ls "1.Common Dataset/BoardEx/" && mkdir -p "1.Common Dataset/BoardEx/cod
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common Dataset/BoardEx/code" && python -c " import io,glob for p in ['pull
[action] Write: G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common Dataset/BoardEx/README.md
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common Dataset" && python -c " import io p='DATA_CATALOG.md' s=io.open(p,e

--- AGENT [2026-07-28 04:50:55] ----------
Line 39 still has the old path -- the escaped backslashes didn't match. Fixing directly:

```
      [action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
      ↪  Dataset/DATA_CATALOG.md
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && git rm -q scripts/pull_boardex_na

--- AGENT   [2026-07-28 04:51:32] ----------------------------------------
Moved. I took the table pull with it -- same reasoning applies, since neither script is specific to this
project.

```
1.Common Dataset\BoardEx\
+-- README.md
+-- code\
|   +-- pull_boardex_na.sh
|   +-- build_boardex_gvkey_link.sh
+-- North America\          (10 tables + 3 link files)
```

The `README.md` sitting beside the data carries the things a future project would otherwise have to
rediscover:

- **`org_composition` vs `org_summary`** -- only the former has role start/end dates, so only it can answer
"who held a role at this firm on date X." `org_summary` is a fiscal-year snapshot.
- **What was deliberately not pulled** -- the 712 GB of network and association tables, with a note to query
them server-side if ever needed, rather than someone assuming the pull was incomplete.
- **Coverage builds over time** -- role dates run to 1900 retrospectively, but the panel goes 6,653 firms in
1990 -> 18,008 in 2000 -> 23,727 by 2007. Pre-2000 is thin.
- **The crosswalk is static**, with the instruction to record a pull date rather than a coverage window.
- **`boardid` = `companyid`**, which isn't obvious from the schema and is what makes the CIK route joinable.

`DATA_CATALOG.md` now points at `BoardEx\code\` and the README. In the project, `scripts/README.md` records
the move so path references in earlier commits still resolve -- and the scripts' full creation history stays
in this repo's git log at `f7e9a8a` and `51e0df0`, which keeps the AFA record intact even though the live
copies moved.

The project's `scripts/` folder is back to just `archive_sessions.py`, which is genuinely project-local.

Next is `exec_roster_l1`. Given where these scripts ended up, worth deciding upfront: a general `gvkey x date
-> executive roster` builder belongs in `BoardEx\code\` as another shared asset, while the cycle-specific
extract keyed to your 1,000 observations is project output and stays in `AI Talk\`. I'd build it in those two
pieces unless you'd rather keep it all in the project.

--- AUTHOR [2026-07-28 05:27:04] --
Now let's build exec_roster_l1. I agree that: 1. we can keep the code BoardEx\code\ and the general output
file in \BoardEx; 2. We have the cycle-specific extract in \2026.07 AI - Political Donation Motive\Data and
the code to extract the cycle-specific sample in \2026.07 AI - Political Donation Motive\Code because they
are for this project but will not only for the AI talk.

--- AGENT   [2026-07-28 05:27:33] --
Creating the folders and checking what I need for the design:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -

--- AGENT   [2026-07-28 05:48:21] ----------------------------------------
`exec_roster_l1` is built, split as you specified.

| Layer | Code | Output |
|---|---|---|
| **General** | `1.Common Dataset\BoardEx\code\build_exec_roster.py` |
`BoardEx\boardex_roles_with_gvkey.csv.gz` (920,707 roles, 14,008 gvkeys) .
`BoardEx\boardex_person_background.csv.gz` (420,759 people) |
| **Project** | `Code\1.build_exec_roster_l1.py` | `Data\exec_roster_l1.csv` |

**6,785 rows covering 857 of 893 firm-cycles (96.0%)**, up to 8 people each, education for 86.9%. Weakest
cycle is 2000 at 82.3%, everything from 2008 on is 97-99%.

The cutoff is enforced in the build rather than left to the model: a role counts only if it started on or
before that cycle's election day and hadn't ended by then. Otherwise a 2010 hire could explain a 2008
donation, which is the leakage the design forbids.

One design choice worth flagging: I kept the general roles file at **role level with exact dates** rather
than expanding to an annual panel. Expanding would have multiplied it roughly tenfold and gained nothing,
since the dates are exact -- any project can cut to whatever frequency it needs.

## Two things the first build got wrong

**Ranking by BoardEx `seniority` surfaced the wrong people.** The first pass returned Vice Presidents and
division heads -- VP of Investor Relations, VP of HR -- because "Senior Manager" is by far the largest tier
while board-level people sit in two much smaller Director tiers. That inverts what matters: a firm's
political connections run through its CEO, chairman, and **outside directors**, since appointing politically
connected people to boards is a standard channel for exactly this motive. Now ranked by office first, board
membership second. Board rows went from 228 to 1,934, and President/CEO, Chairman/CEO, and Independent
Director now lead.

**BoardEx's `9999` no-date sentinel was printing as a graduation year** -- "Johns Hopkins University,
Attended 9999". Suppressed.

Both fixes are in the scripts, and both files were rebuilt from scratch.

## One note

WRDS started refusing connections partway through -- `SSL connection has been closed unexpectedly`, probably
a session limit after this many pulls. It didn't matter, since everything was built from the local gzipped
tables, which is the better provenance anyway. But if you need WRDS in the next session and it's still
refusing, that's the likely cause.

The prompt now points category 4 at the roster for the firm half and reserves search for the candidate half.
Nothing is left unbuilt before the 200-row pilot.

--- AUTHOR  [2026-07-28 05:54:35] ----------------------------------------
1. I've reactivated WRDS access. In case you need it again, you can let me know and I will pass the Duo
request. 2. What executive levels we consider for having a social connection with political candidates now?
Should we restrict to certain level of executives and board members for this project? Let's confirm this
before trying the first 200-row pilot.

--- AGENT   [2026-07-28 05:54:57] ----------------------------------------
Good to know on WRDS -- I'll flag it if I need a Duo push.

On executive levels: right now there's **no restriction at all**, only a priority ordering with a cap of 8.
Let me show you what that actually produces.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python -c " import pandas as pd,

--- AGENT   [2026-07-28 05:55:25] ----------------------------------------
That analysis has a bug that reveals a real one in the build script: matching `"PRESIDENT"` as a substring
catches **"Vice President"**. So VPs have been ranked as if they were the President. Let me measure it
```

```
properly:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python -c " import pandas as pd,

--- AGENT   [2026-07-28 05:56:21] ----------------------------------------
Now the real picture. Two findings:

**A bug in the ranking.** `person_rank` matches `"PRESIDENT"` as a substring, so **"Vice President - HR"**
scores as if it were the President. That's why VPs kept surfacing despite my earlier "fix."

**What's actually in the roster today:**

| | rows | share |
|---|---|---|
| C-suite (CEO, CFO, COO, President, Chairman, Founder, GC) | 3,042 | 44.8% |
| Board members | 486 | 7.2% |
| Government/public/regulatory affairs | 117 | 1.7% |
| Division presidents/CEOs | 350 | 5.2% |
| **Ordinary VPs** -- HR, Investor Relations, Ops, Marketing, Tax, Finance | **2,790** | **41.1%** |

So **46% of what the model would read is divisional managers.** A congressman sharing an alma mater with a VP
of Tax is not what "the firm has a social tie to this candidate" means -- PAC giving is decided by senior
management and the PAC committee. Worse, every extra person multiplies the chance of a coincidental school or
employer overlap, and the prompt tells the model to find "specific and named" ties. That invites false
positives in a category you expect to be rare, where precision matters far more than recall.

**Restricting costs almost nothing:** C-suite + board + government affairs retains **856 of 857 firm-cycles
(99.9%)**, at mean 4.3 people each.

I'd keep government-affairs roles explicitly even though they're VPs -- the VP of Government Relations is
precisely the person who carries political relationships, arguably likelier to have a tie than the CFO. A
blanket "no VPs" rule would drop the most relevant non-C-suite category there is.
      [action] AskUserQuestion:

--- AGENT   [2026-07-28 06:01:06] ----------------------------------------
Yes -- and the reason is stronger than tidiness, which is worth being precise about since it ends up in the
paper.

**The criterion isn't seniority. It's whether the person plausibly influences or executes political giving.**

Corporate PAC contributions are decided by senior management and a PAC committee, with the government-affairs
function running the relationships and the board approving the policy. A VP of Tax has no say in which House
candidate receives $5,000. So if the model codes a social tie from that person's college roommate, the label
names something that could not have caused the donation.

That matters directly for the second half of your paper. You intend to link motives to firm outcomes. A
motive category is only interpretable there if it identifies a plausible *channel* -- the tie has to be one
that could have produced the donation and could produce the benefit. A coincidental alma mater three levels
down the org chart fails that test, and a referee will say so.

It also gives you a sentence you can defend in print: *"We restrict to officers, directors, and the
government-affairs function, since these are the people who decide and execute corporate political giving."*
Compare that with *"we include the top eight BoardEx people by role name,"* which is what the current file
does.

This is why **government-affairs VPs stay in even though they sit below the C-suite** -- they're junior by
title but they own the political-relationship function. Restricting by hierarchy level alone would drop
exactly the wrong people. The restriction is by role and authority, and level is only a proxy for it.

So: your selection of **C-suite + board + government affairs** is the right rule, and I'll implement it along
with the `"Vice President"` substring fix.

One thing still open -- **how many people per firm-cycle to carry**. Under the restricted scope the mean is
4.3, so the cap rarely binds, but a real board runs 9-12 members. Keep the cap at 8, and a large firm's board
gets truncated with the dropped directors chosen by role-name ordering rather than anything substantive.
Raise it to 12 and full boards survive, at the cost of slightly more text per firm-cycle where a genuine
board exists.

I'd raise it to 12. Say the word and I'll rebuild.
```

```
--- AUTHOR  [2026-07-28 06:01:13] ----------------------------------------
I don't understand why we need to put a cap after we restrict the level of exectuives we will use

--- AGENT   [2026-07-28 06:01:25] ----------------------------------------
Fair challenge -- let me check whether it's needed at all rather than assume it. The uncapped distribution
under the restricted scope:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -c "
      ↪  import pandas as pd S='1.Common Dataset/BoardEx/' CUT={2000:

--- AGENT   [2026-07-28 06:02:01] ----------------------------------------
I need to correct myself: **the "mean 4.3" figure was wrong.** I computed it on the already-capped file, so
it could never exceed 8. Uncapped, the restricted scope gives **mean 23.4 people per firm-cycle, median 19,
max 176** -- 97% exceed 8. The restriction does not bound the roster, so a cap genuinely is needed.

Let me find out why it's so large, because that may be the real problem:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -c "
      ↪  import pandas as pd S='1.Common Dataset/BoardEx/' CUT={2000:

--- AGENT   [2026-07-28 06:02:34] ----------------------------------------
You're right, and it reframes the problem correctly: **if the restriction is right, take everyone who
qualifies.** A cap is only papering over a definition that's too loose. Let me find out what's actually in
these counts:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -c "
      ↪  import pandas as pd S='1.Common Dataset/BoardEx/' CUT={2000:

--- AGENT   [2026-07-28 06:03:06] ----------------------------------------
Found it. **JPMorgan Chase 2014: 540 people** -- but the actual board is 15 Supervisory Directors plus 2
Executive Directors. The other 529 are Managing Directors and divisional officers.

My patterns were leaking: `\bCEO\b` matched **"Division CEO"** (14 of them), `\bCHAIRMAN\b` matched "Division
Vice Chairman" (11), `GENERAL COUNSEL` matched "MD/Associate General Counsel". The division exclusion only
guarded the `PRESIDENT` branch, not the others.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -c "
      ↪  import pandas as pd S='1.Common Dataset/BoardEx/' CUT={2000:

--- AGENT   [2026-07-28 06:03:44] ----------------------------------------
Much better -- mean 13.5, median 12, max 55. That's a real firm-size distribution rather than an artifact.
One variant left to check, since `\bCHIEF\b` still catches every Chief-X officer at a big bank:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -c "
      ↪  import pandas as pd S='1.Common Dataset/BoardEx/' CUT={2000:

--- AGENT   [2026-07-28 06:04:23] ----------------------------------------
One bug in my own test: `Vice President - Government Affairs` contains "VICE PRESIDENT", so the subordinate
filter was **dropping the government-affairs people I meant to keep**. Correcting that and settling the
numbers:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -c "
      ↪  import pandas as pd S='1.Common Dataset/BoardEx/' CUT={2000:

--- AGENT   [2026-07-28 06:04:50] ----------------------------------------
You're right -- no cap. Implementing:

JPMorgan 2014 is now **29 people** -- 9 independent directors, 4 other directors, 3 vice chairmen, 3 general
counsel, plus government relations. That's a real board and officer group, down from 540.
      [action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/Guidance/classification_prompt_v1.md
      [action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/Guidance/classification_prompt_v1.md
```

```
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && git add -A && git commit -q -F -

--- AGENT   [2026-07-28 06:06:54] ----------------------------------------
Your question was the right one, and pushing on it exposed a bug I'd have shipped.

**The cap wasn't solving a real problem.** It was hiding leaky role patterns. The divisional guard only
applied to the `PRESIDENT` branch, so `\bCEO\b` matched **"Division CEO"**, `\bCHAIRMAN\b` matched "Division
Vice Chairman", and `GENERAL COUNSEL` matched "MD/Associate General Counsel". JPMorgan 2014 came out at **540
people** against a real board of 17. With a cap of 8 that looked fine -- the truncation concealed it.
Uncapped, the median was 19 and the max 176, which is exactly why a cap seemed necessary.

I also caught a second error while checking: my own subordinate filter was **silently dropping all 511
government-affairs people**, because "Vice President - Government Affairs" contains "VICE PRESIDENT". The
category I'd argued hardest to keep was being deleted by the rule meant to protect it.

## Where it lands

Selection is now by **authority over political giving**, not seniority:

| Group | Rows |
|---|---|
| Board -- all executive and supervisory directors | 9,376 |
| Core offices -- CEO, CFO, COO, President, Chairman, Founder, General Counsel | 822 |
| Government/public/regulatory affairs, any level | 511 |

**10,709 rows, 854 of 893 firm-cycles (95.6%), median 12 people, p90 17, max 33** -- a firm-size
distribution, so nothing is truncated. JPMorgan 2014 is 29 people. Education coverage rose from 86.9% to
95.2%, because directors are far better documented in BoardEx than VPs.

A `group` column marks each person, so you can test later whether ties through directors behave differently
from ties through officers.

The prompt now tells the model that everyone in the file qualifies as "the firm," and that a tie to someone
*outside* it -- a divisional VP, a regional manager -- does not support the category, because that person
could not have caused the donation.

Nothing is left unbuilt. The pilot can run on `random_1000_house_firm_cand_cycle_don_first200_for_llm.csv`
whenever you're ready.

--- AUTHOR  [2026-07-28 06:08:47] ----------------------------------------
Ok now let's try the pilot and you're free to search anywhere for the information you need to for accruact
classification

--- AGENT   [2026-07-28 06:09:11] ----------------------------------------
Let me start by loading the pilot rows in a form I can actually reason over.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python -c " import pandas as pd d
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python - <<'PY' import pandas as

--- AGENT   [2026-07-28 06:10:38] ----------------------------------------
Let me screen for social ties systematically before classifying, since that's the one category I can't judge
from the row alone.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -
      ↪  <<'PY' import pandas as pd, re P='2026.07 AI - Political Donati

--- AGENT   [2026-07-28 06:11:11] ----------------------------------------
The surname screen produced only two coincidences (Lewis Jordan != John Lewis; John Weinberg != Chris John)
-- no real ties there. Let me read the rest of the rows:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && sed -n '51,150p' .pilot_view.txt
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && sed -n '151,270p' .pilot_view.txt
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && sed -n
      ↪  '271,400p' "2026.07 AI - Political Donation Motive/.pilot_view.tx

--- AGENT   [2026-07-28 06:14:45] ----------------------------------------
I've read all 200. Let me check a few plausible social-tie cases before finalizing, since that's the category
```

```
I can't judge from the row alone.
      [action] ToolSearch: select:WebSearch
      [action] WebSearch: Richard Baker congressman Louisiana biography education Louisiana State University
      ↪  before Congress
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python -c " import pandas as pd e

--- AGENT   [2026-07-28 06:15:31] ----------------------------------------
No LSU overlap in AmSouth's 15-person roster -- no tie. The method works; the base rate is just low. Now
writing the 200 classifications:
      [action] Write: C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-Universit
      ↪  y-PhD-research-projects-2026-07-AI---Political-Donation-Motive

      ↪  Political Donation Motive" && python - <<'PY' import sys, panda

--- AGENT   [2026-07-28 06:17:46] ----------------------------------------
Empty columns come back as float64. Casting first:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python - <<'PY' import sys, panda

--- AGENT   [2026-07-28 06:18:14] ----------------------------------------
Let me run the gate diagnostic -- the question of whether the labels carry information beyond the mechanical
indicators:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python - <<'PY' import pandas as
      [action] Write: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/Guidance/_runlog.md
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && git add -A && git commit -q -F -

--- AGENT   [2026-07-28 06:19:48] ----------------------------------------
Pilot complete -- `AI Talk/random_1000_house_firm_cand_cycle_don_20260728_claude-opus-5_first200.csv`,
conditions in `Guidance/_runlog.md`.

| Motive | n | share |
|---|---|---|
| committee | 83 | 41.5% |
| incumbent_contestant | 77 | 38.5% |
| geography | 36 | 18.0% |
| others | 4 | 2.0% |
| **social_ties** | **0** | **0.0%** |

## The gate result -- the thing you actually wanted to know

**40.5% of the labels cannot be recovered from the mechanical indicators.** A lookup on district match x
state match x incumbency x has-committee x power gives 9 cells and reproduces 59.5% of labels, against a
41.5% modal baseline.

The judgment concentrates exactly where it should: **among the 170 rows carrying a committee seat, I assigned
`committee` to only 48.8%.** The rest sit on committees with no jurisdiction over that firm -- Appropriations
for a water-heater manufacturer, Rules for a title insurer, Armed Services for a car-rental company. A "has a
committee seat" dummy would be wrong more than half the time. That jurisdiction call is the measure's engine,
and it's what the human coding needs to validate.

## Three things you need to decide

**Geography as written almost never fires.** Only **3 of 200** match at district level -- Ball/Udall,
Churchill Downs/Northup, Mandalay/Herrera. Another 33 share a state. Applying the definition strictly makes
geography 1.5% of the sample. I treated state-level overlap as a weaker form and placed it *below* committee
in priority rather than above, which is a deviation from the stated order and moves 16.5% of the sample. This
needs your call before the remaining 800.

**Social ties returned zero for a structural reason, not an empirical one.** The firm half worked -- the
roster covered 157 firm-cycles. The candidate half didn't: establishing ties needs a biography for each of
159 candidates checked against ~12 executives, roughly 1,900 pairwise comparisons. That isn't an ad-hoc
search task. I worked one case fully to prove the method -- AmSouth -> Rep. Richard Baker, whose LSU
background I retrieved and checked against all 15 of the firm's officers and directors. No overlap, no tie.
**Category 4 needs a candidate-biography file built the way the exec roster was.**
```

Leadership has no home in the taxonomy. Six rows involve the Speaker, a Majority Leader, whips, or the Budget chair, where the draw is agenda-setting power rather than jurisdiction. They fell to `incumbent_contestant`, which is where v1 sends them, but the label understates what's happening.

Two weaknesses worth knowing: Appropriations is under-assigned because the sample records membership without subcommittee, so I can't tell defence from energy-and-water; and Ways and Means is under-assigned because corporate tax touches everyone, so I credited it only for distinctive stakes like excise, tariffs, and Medicare. A different coder would draw both lines elsewhere -- which is precisely what the blind 200 will reveal.

Sources: [BAKER, Richard Hugh -- US House of Representatives History, Art & Archives](https://history.house.gov/People/Detail/8866)

--- AUTHOR [2026-07-28 06:36:54] ----------
1. That's OK if we only have small percentage of donations for geography, which is exactly I'd like to find. 2. Is there any data available on canddiate background so that we can have better information for social tie classification? 3. For leader, as long as it's a leader role, such as Speaker, a Majority Leader, whips, or the Budget chair, the leader field should be filled. We don't need to consider committee when assigning the powerful and leader candidate.

--- AGENT [2026-07-28 06:37:39] ----------
Let me research the candidate-background question first, since that's the substantive one.
[action] WebSearch: congress-legislators dataset YAML bioguide FEC candidate ID wikidata members of Congress structured biographical data

--- AGENT [2026-07-28 06:38:00] ----------
`unitedstates/congress-legislators` carries **FEC candidate IDs** -- which are exactly your `cand_id`. Let me verify it actually matches your sample:
[action] Bash: cd "C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-University-PhD-research-projects-2026-07-AI---Political-Donation-Mo

--- AGENT [2026-07-28 06:38:20] ----------
Endorsed on the jurisdiction test -- good, that's the measure's engine. Now let me check whether the FEC IDs actually match your candidates:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python - <<'PY' import pandas as pd, ast S=r"C:\Users\DevinZ\AppData\Loc

--- AGENT [2026-07-28 06:38:58] ----------
91% of candidates and 94.1% of observations match, each with a `bioguide_id` and `wikipedia_id`. Let me confirm the biographical detail is actually retrievable:
[action] Bash: cd "C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-University-PhD-research-projects-2026-07-AI---Political-Donation-Mo

--- AGENT [2026-07-28 06:39:40] ----------
Wikidata returns `educated_at` -- four institutions for Shimkus. **The pipeline is viable.** Now let me apply your three decisions. First, the leadership field in the build script:
[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/AI Talk/2.add_committee_fields_and_classi
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/AI Talk" && python -c " import io p='
[action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation Motive\AI Talk"; $p = Start-Proces

--- AGENT [2026-07-28 06:40:21] ----------
Now applying your geography decision -- strict district-level only -- and re-emitting the labels:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && python - <<'PY' import sys, panda
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && python -c " import pandas as pd d
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance" && python - <<'PY' import i

--- AGENT [2026-07-28 06:41:36] ----------
Yes -- exactly right, and it's a stronger argument than mine. A House member represents **one** district, so district-level is the natural unit and state overlap is just a coarser proxy for it. (Worth noting for later: this wouldn't hold if you extend to Senate candidates, since a senator represents the whole state -- there, state match *is* the district match.)

Already applied. Let me update the runlog and commit:

```
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/Guidance" && python - <<'PY' import i

      ↪  Political Donation Motive/Guidance" && python - <<'PY' import i

--- AGENT   [2026-07-28 06:48:53] ----------------------------------------
Yes -- candidate background data exists, it's public, and it joins directly on your `cand_id`.

## The source

`unitedstates/congress-legislators` maps **FEC candidate IDs** to bioguide and Wikipedia IDs. Wikidata then
supplies `educated_at`, `employer`, `occupation` as structured fields. Built to `1.Common
Dataset\Politics\Candidate Background\` -- **1,714 FEC IDs, 99.5% with education**, covering **91% of your
distinct candidates and 94.1% of observations**. The 9% missing are candidates who never served, so they have
no legislator record.

## The retry -- and why social ties is still zero

Matching candidate institutions against the executive roster gives **62 shared-institution pairs across 29 of
the 200 rows**, saved as `Data/social_tie_shortlist_first200.csv`. Synovus has seven University of Georgia
directors and a UGA congressman; Northwest Airlines has five Harvard people and a Harvard congressman.

**I promoted none of them**, because a shared institution is not a tie under the standard your own protocol
sets: *"specific and named... overlapping 1979-1981."* Wikidata's `educated_at` came back without its date
qualifiers, so I cannot test overlap. Harvard has hundreds of thousands of living alumni -- five Harvard
directors and a Harvard congressman is Harvard being large, not a relationship. Promoting these would be
precisely the "manufacture ties to avoid Others" the prompt warns against, and it would put unverifiable
labels into the outcome analysis.

**The next step is tractable and cheap:** pull the P69 date qualifiers for candidate graduation years and
re-run those 62 pairs with a +/-4-year window. Executive graduation years are already present for 76% of
them. That's when category 4 can be assigned honestly.

Two matcher bugs worth recording, both caught by reading output rather than trusting counts: single-token
matching scored "American University" against "American Board of Cardiovascular Disease", and stripping
"state"/"college" conflated **Mississippi State with Ole Miss** and **Boston College with Boston University**.

## Where the pilot now stands
```

Motive	n	share
incumbent_contestant	110	55.0%
committee	83	41.5%
others	4	2.0%
geography	3	1.5%
social_ties	0	0.0%

Leadership fields are built -- `cand_leader_l1` (16 rows), split into `cand_chamber_leader_l1` (4) and `cand_cmte_chair_l1` (12) -- filled whenever the role exists, without testing jurisdiction.

One question I deferred rather than guess at. You said not to consider committee when assigning powerful and leader candidates. Six of the 16 leader rows are chairs of committees that *do* have jurisdiction over the firm -- Bill Young chairing Appropriations while Triumph Group supplies aerospace parts. Should those stay `committee`, or does the leader role take precedence? It changes 6 of 200 here and would change more at scale.

Sources: [unitedstates/congress-legislators](https://github.com/unitedstates/congress-legislators) . [BAKER, Richard Hugh](https://history.house.gov/People/Detail/8866)

--- AUTHOR [2026-07-28 06:58:23] ----------
1. As for "Six of the 16 leader rows are chairs of committees that do have jurisdiction over
the firm -- Bill Young chairing Appropriations while Triumph Group supplies aerospace parts.", I think the committee category is used and then the powerful candidate field is filled as well. Don't we have the powerful_candidate field in the data? Should we have one? 2. Yeah I think we can do this "pull the P69 date qualifiers for candidate graduation years and
re-run those 62 pairs with a +/-4-year window" for social tie.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && python -c " import pandas as pd d

--- AGENT [2026-07-28 06:59:02] ----------
Nearly identical -- 139 of 140 overlap. Let me find the one discrepancy:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && python -c " import pandas as pd d

--- AGENT [2026-07-28 06:59:22] ----------
A truncation bug, and a real one: `gen str80 entry` cut **"(ranking minority)"** to "(ranking minor" because the committee name -- *"events surrounding the 2012 terrorist attack on benghazi (select)"* -- is long. Let me check how widespread that is and fix:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && python -c " import pandas as pd d

--- AGENT [2026-07-28 06:59:42] ----------
Only that one row of 1,000 was affected -- `cmte_l1` maxes at 177 characters, well under its limit, and the 17 other odd endings are chamber-leadership rows that legitimately have no parenthetical. Fixing both issues:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/AI Talk" && python - <<'PY' import io
[action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research ↪ projects\2026.07 AI - Political Donation Motive\AI Talk"; $p = Start-Proces
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/AI Talk" && python -c " import pandas

--- AGENT [2026-07-28 07:00:33] ----------
Fixed and verified: `cand_power_l1` (140) now decomposes exactly into chamber leaders (27) and committee chairs/ranking members (114), with no residual.

Now the graduation years for social ties:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common ↪ Dataset/Politics/Candidate Background/code" && python - <<'PY' impo
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -c " ↪ import pandas as pd, re cb=pd.read_csv('1.Common Dataset/Pol

--- AGENT [2026-07-28 07:03:45] ----------
87.9% now carry graduation years. Re-running the 62 pairs with the +/-4-year overlap test:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python - ↪ <<'PY' import pandas as pd, re P='2026.07 AI - Political Donati

--- AGENT [2026-07-28 07:04:36] ----------

```
5 pairs clear the overlap test. Three of them aren't outranked by geography or committee, so they become
social ties:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python - <<'PY' import pandas as
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python - <<'PY' import io p='Guid

--- AGENT   [2026-07-28 07:05:45] ----------------------------------------
Both done.

## 1. You already have the powerful-candidate field

`cand_power_l1` **is** it -- built from the Stewart-Woon `seniorpartymember` codes, covering chairs, ranking
members, Speaker, Leaders, Whips. The `cand_leader_l1` I added yesterday was a duplicate of it, so I've
dropped it and kept only the informative split:

| Field | n (of 1,000) |
|---|---|
| `cand_power_l1` | 140 |
| + `cand_chamber_leader_l1` -- Speaker, Leaders, Whips | 27 |
| + `cand_cmte_chair_l1` -- chair, ranking, vice/co-chair | 114 |

The two splits now decompose the umbrella exactly. Checking that turned up a **truncation bug**: `str80` on
the role string cut *"(ranking minority)"* to *"(ranking minor"* for Tammy Duckworth, because her select
committee is named *"events surrounding the 2012 terrorist attack on benghazi"*. Widened to `str160`; one row
of 1,000 was affected.

Your rule is implemented: **committee wins when jurisdiction applies, and the power field is filled
regardless.** The category records *why* the donation was made; the field records *who the candidate was*.
Bill Young stays `committee` with `cand_cmte_chair_l1 = 1`.

## 2. Social ties -- now verifiable

Graduation years are in (87.9% of candidates carry at least one dated institution). Re-testing the 62 pairs
with +/-4 years:

| | pairs |
|---|---|
| **Years overlap** | **5** |
| Same institution, no overlap -- gaps of 5 to 40 years | 36 |
| Undated on one side | 21 |

**That 36 is the number worth keeping in mind** -- it's the false-positive rate a naive institution match
would have injected. Nearly two-thirds of "shared school" matches are people who were never there at the same
time.

Three of the five became `social_ties`; the other two already carried `committee`, which outranks social
ties, so the tie sits in `reasoning` instead:

- **Avis Budget -> Maloney** -- Harvard 1972 / director Len Coleman 1976
- **Con Edison -> Velazquez** -- NYU 1976 / director Sally Hernandez-Pinero, NYU Law 1977
- **AmSouth -> Vitter** -- Harvard 1983 / director Cleo Thomas, JD 1982

All three at **confidence 2, deliberately**. Same institution plus adjacent years is the test your protocol
specified and it passed -- but co-attendance is not proof of acquaintance. Filter on confidence before
category 4 enters any outcome regression.

## Final pilot

| Motive | n | share |
|---|---|---|
| incumbent_contestant | 107 | 53.5% |
| committee | 83 | 41.5% |
| others | 4 | 2.0% |
| geography | 3 | 1.5% |
| social_ties | 3 | 1.5% |

The candidate-background builder is a reusable shared asset at `1.Common Dataset\Politics\Candidate
Background\` -- 1,714 FEC IDs with education, employer, and occupation, joining directly on `cand_id` for any
politics project.
```

Next natural step is the blind human coding of these same 200, which is what tells you whether the committee-jurisdiction judgment -- the 40.5% the mechanical indicators can't reach -- is actually right.

--- AUTHOR [2026-07-28 07:11:16] ----------
1. Let's change social ties classification to pairs with +/-5 years. 2. Powerful candidate and leader candidate variables seem redundant, let's ok keep one Powerful candidate variable. 3. What does "cand_cmte_chair_l1" mean?

--- AGENT [2026-07-28 07:11:31] ----------
Answering (3) first since it decides (2): **`cand_cmte_chair_l1`** meant *"=1 if the candidate chairs, or is ranking minority member / vice-chair / co-chair of, any committee"* -- with `_l1` meaning **lagged one cycle**, i.e. the *sitting* Congress rather than the one the election produces. Same suffix convention as `cmte_l1`.

And you're right that it's redundant -- but for a better reason than I gave: `cmte_l1` already spells out `"ways and means (chair)"` and `"majority whip"`, so the split is recoverable any time. One flag plus the annotated list loses nothing.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python - ↪ <<'PY' import pandas as pd, re P='2026.07 AI - Political Donati

--- AGENT [2026-07-28 07:12:10] ----------
+/-5 adds three observations (8 total with an overlapping tie). Implementing both changes:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/AI Talk" && python - <<'PY' import io
[action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research ↪ projects\2026.07 AI - Political Donation Motive\AI Talk"; $p = Start-Proces
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && python - <<'PY' import sys, panda
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && python - <<'PY' import io p='Guid

--- AGENT [2026-07-28 07:14:03] ----------
Both applied.

3. What `cand_cmte_chair_l1` meant

`=1` if the candidate chaired -- or was ranking minority member, vice-chair, or co-chair of -- **any** committee. The `_l1` suffix means **lagged one cycle**: the Congress *sitting* when the donation was made, not the one the election produced. Same convention as `cmte_l1`. It's now removed.

2. One powerful-candidate field

Only `cand_power_l1` survives -- chairs, ranking members, Speaker, Leaders, Whips, vice/co-chairs, per the Stewart-Woon codes. 140 of 1,000.

Nothing is lost, which is what makes your call right: `cmte_l1` already reads `"ways and means (chair)"` or `"majority whip"`, so if you later want to separate agenda-setting leadership from committee chairmanship, it's one line of string matching -- no column needed.

1. Social ties at +/-5 years

Window	pairs	observations
+/-4	5	5
+/-5 (adopted)	**11**	**8**
+/-6	14	10

Four became `social_ties`; four more overlap but already carry `committee`, which outranks them, so the tie is recorded in `reasoning` instead.

Firm -> candidate	Institution	Gap
Con Edison -> Velazquez	NYU	1 yr
AmSouth -> Vitter	Harvard	1 yr
Avis Budget -> Maloney	Harvard	4 yrs
Synovus -> Kingston	Georgia (3 UGA directors)	5 yrs

I graded confidence **2 for gaps <=3 years and 1 for 4-5**, because at a five-year gap two undergraduates on

four-year degrees would not actually have been on campus together -- Kingston graduated UGA in 1978, the three Synovus directors in 1973. It may still be a real network (a Georgia bank, a Georgia congressman, a shared alma mater), but it isn't co-attendance. `year_gap` is written to the shortlist file, so you can retighten to +/-3 or +/-4 without re-running anything.

Final pilot

Motive	n	share
incumbent_contestant	106	53.0%
committee	83	41.5%
social_ties	4	2.0%
others	4	2.0%
geography	3	1.5%

Search was used on 9 rows, mean confidence 3.44. The blind human coding of these same 200 is the next thing that would actually test the labels -- particularly the committee-jurisdiction calls, which are the 40.5% the mechanical indicators can't reproduce.

--- AUTHOR [2026-07-28 07:19:45] ----------
1. In terms of our decision and data used on social tie classification, have you updated the information in classification_prompt_v1.md? Do we also need to update taxonomy_decisions.md and run_procedure.md for other decisions we've mad? 2. I'm going to write an email to my coauther regarding the result. I can copy and past the Final pilot summary but I'd also like to make Stefan understand major steps and decisions. The trail result csv, taxonomy_decisions.md, classification_prompt_v1.md will be attached to the email. Can you retrun a text (not too lengthy) I should include in the email to faciliate his understanding of our exercise?

--- AGENT [2026-07-28 07:19:54] ----------
Let me audit the guidance files for stale content before drafting the email.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance" && echo "=== stale referenc

--- AGENT [2026-07-28 07:20:13] ----------
Two real gaps: the taxonomy still lists the deleted `cand_leader_l1`, and **the prompt has no mention of the candidate-background file at all** -- it still tells the model to search for biographies that now sit in a file. Fixing:
[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance/taxonomy_decisions.md
[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance/classification_prompt_v1.md
[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance/classification_prompt_v1.md
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance" && python - <<'PY' import i

--- AGENT [2026-07-28 07:21:31] ----------
All stale references gone -- zero across all four files.

Guidance now synced

`classification_prompt_v1.md` had the biggest gap: it still instructed the model to *search* for candidate biographies that now sit in a file. It now lists `candidate_background_fecid.csv` as an input and replaces the vague "specific and named" standard with the two-condition test -- same institution after sub-school normalisation **and** graduation years within +/-5 -- plus the fact that 62 pairs shared an institution while only 11 also overlapped in time.

`taxonomy_decisions.md` listed the deleted `cand_leader_l1`. Replaced with the `cand_power_l1` rule and your decision that committee wins while the power field is filled anyway.

`run_procedure.md` now carries the run-1 gate benchmark as the standard later runs get compared against.

Draft email text

> Stefan,
>
> Attached are the pilot results for the donation-motive exercise, plus the two documents that govern it: the taxonomy and the prompt.

```
>
> **What we built.** A 1,000-observation trial sample at the firm-candidate-cycle level (House, 2000-2022,
Compustat firms) carrying donation and firm information only. Election results and committee assignments are
deliberately excluded from the classification sample, because both are realized *after* the donation -- the
2000 cycle maps to the 107th Congress, seated January 2001. Committee data comes back in lagged to the
Congress sitting when the donation was made. That costs us less than I expected: measuring the Stewart-Woon
data, a member holding a committee seat keeps it into the next Congress 80.6% of the time, and 97-98% for
Ways and Means, Energy and Commerce, and Appropriations -- the committees a firm would actually target.
>
> Two companion files supply what the sample can't. The firm side: each firm's officers, directors and
government-affairs staff as they stood the day before that cycle's election, from BoardEx. The candidate
side: education with graduation years, built from the congress-legislators crosswalk and Wikidata, joining
directly on the FEC candidate ID.
>
> **Pilot results** on the first 200 observations are in the attached CSV, with reasoning and sources on
every row.
>
> **The result that matters.** Of the 170 observations where the candidate held a committee seat, only 48.8%
were classified as committee-motivated -- the rest sit on committees with no jurisdiction over that firm
(Appropriations for a water-heater manufacturer, Rules for a title insurer). More broadly, 40.5% of the
labels cannot be reproduced by any lookup on the mechanical indicators we already have. That jurisdiction
judgment is what the LLM is actually contributing.
>
> **Three decisions I'd like your view on.** Geography fires only on a district match, which makes it 1.5% of
the sample -- three observations. Social ties require the same institution *and* graduation years within five
years; institution alone would have given us 29 observations instead of 8, and most of those people were
never on campus together. And party/ideology is still out of the taxonomy -- I think it's the natural null
category for the outcome analysis, but it overlaps heavily with the incumbent category and needs a
firm-partisanship variable to separate cleanly.
>
> **Next step** is coding 200 observations by hand, blind to the model's labels, to check the
committee-jurisdiction calls. That's the number the paper will live on.
>
> Devin

Trim the persistence statistics or the third decision if you want it shorter -- those are the two places a
busy reader would skim. I'd keep the 48.8% sentence intact; it's the one number that says why the project is
worth doing.

--- AUTHOR  [2026-07-28 07:23:52] ----------------------------------------
I only need the text on the classification procedure for him rather than the whole email. He knows the
background, all data decisions, and categorgy. What he doesn't understand is the classificaiton details,
issues, and our decisions, this is the text I'd like you to have for me

--- AGENT   [2026-07-28 07:24:20] ----------------------------------------
> **How the classification ran.** Each observation was worked through the categories in priority order,
stopping at the first one the pre-election record could establish. Geography and incumbency are settled
mechanically by the sample. Committee is a judgment call, and it is where nearly all the work went. Social
ties are settled by matching the two companion files. Search was used on 9 of the 200 rows.
>
> **One thing I had to change before running.** Taken in numeric order, the priority rule breaks: every
candidate is by definition either an incumbent or a contestant, so category 3 is universally true and would
absorb everything that isn't geography or committee -- social ties could never fire at all. I reordered it to
put the firm-relational categories first: **geography -> committee -> social ties -> incumbent/contestant ->
others**. Category 3 then becomes the explicit default, which is what it actually is. Its real meaning is
generic access.
>
> **The committee call is the substance of the exercise.** 170 of the 200 candidates held a committee seat,
but I assigned the committee motive to only 48.8% of them. The rest sit on committees with no jurisdiction
over that firm -- Appropriations for a water-heater manufacturer, Rules for a title insurer, Armed Services
for a car-rental company. A "holds a committee seat" dummy would be wrong more than half the time. More
generally, 40.5% of the labels cannot be reproduced by any lookup on the mechanical indicators we already
have, and that residual is concentrated here.
>
> **Two places where I had to draw a line, and a different coder would draw it elsewhere.** Ways and Means
touches every corporation through the tax code, so crediting it literally would make it meaningless; I
credited it only where the firm has a distinctive stake -- excise taxes for tobacco and spirits, tariffs for
import-heavy retailers, Medicare for pharmacy benefit managers. Appropriations is worse: our data records
committee membership without subcommittee, so I cannot tell defence from energy-and-water, and I credited it
only where the firm sells into federal programmes. Both lines are under-inclusive by construction.
```

```
>
> **Social ties needed a stricter test than I first used.** Matching candidate and executive institutions
gave 62 pairs across 29 observations, but that is mostly institution size rather than acquaintance --
Northwest Airlines had five Harvard directors and a Harvard congressman. Requiring graduation years within
five years cuts it to 11 pairs across 8 observations. Four of those are already explained by committee, which
outranks social ties, so the tie is noted in the reasoning rather than overriding the label; four became
social ties, all at low confidence. Co-attendance is evidence of possible acquaintance, not of a relationship.
>
> **Three known weaknesses.** Leadership has no home in the taxonomy -- donations to the Speaker, the
Majority Leader and the Budget chair fell to the incumbent category, which understates what

and you don't need to sumary the findings. He can read the table. No one likes lengthy email. The email
should carry real things that answer his potential questions and understand the isses and subsequent
decisions we made

--- AGENT   [2026-07-28 07:25:56] ----------------------------------------
> Stefan -- a few notes on how the classification actually worked, and where I had to make calls.
>
> **Priority order.** Taken numerically it breaks: every candidate is by definition an incumbent or a
contestant, so category 3 is always true and would swallow everything that isn't geography or committee --
social ties could never fire. I ran it as **geography -> committee -> social ties -> incumbent/contestant**,
putting the firm-relational categories first. Category 3 becomes the explicit default, which is what it
really is: generic access.
>
> **Committee.** I tested jurisdiction over *that firm*, not whether the candidate holds a seat. 170 of 200
held one; I assigned committee to 48.8%. The rest sit on committees with no bearing on the firm --
Appropriations for a water-heater maker, Rules for a title insurer. This is where the judgment is, and it's
what the human coding should check.
>
> Two lines I drew that you may want drawn differently. Ways and Means touches every corporation through the
tax code, so I credited it only for distinctive stakes -- excise for tobacco, tariffs for import-heavy
retailers, Medicare for PBMs. Appropriations is worse: our data has committee membership but not
subcommittee, so I can't separate defence from energy-and-water, and I only credited it where the firm
clearly sells into federal programmes. Both are under-inclusive by construction.
>
> **Social ties.** Matching candidate and executive schools gave 62 pairs -- but that's mostly institution
size, not acquaintance (Northwest Airlines had five Harvard directors and a Harvard congressman). Adding a
five-year graduation-window test cuts it to 11. All are flagged low confidence: co-attendance isn't a
relationship.
>
> **Two gaps.** Donations to the Speaker, Majority Leader and Budget chair have nowhere to go and fell to
incumbent -- the label understates them. And four observations were unclassifiable because the firm identity
is missing from the sample.
>
> Devin

--- AUTHOR  [2026-07-28 07:30:12] ----------------------------------------
1. You didn't include the data source for social ties, which is key information as well. You didb't include
the meaning of confidence values we have, what we want to show in reasoning, and the best way to read the
filled columns by you in the output csv. 2. I don't think it's our data issue that Appropriations doesn't
have subcommittee, don't hype the situation.

--- AGENT   [2026-07-28 07:30:31] ----------------------------------------
> Stefan -- a few notes on how the classification actually worked, and where I had to make calls.
>
```

Matching schools alone gave 62 pairs -- but that's mostly institution size, not acquaintance (Northwest Airlines had five Harvard directors and a Harvard congressman). Requiring graduation years within five years cuts it to 11.
>
> **Reading the output.** `motive` is the category; `motive_detail` names the specific thing behind it (which district, which committee and the member's role on it, which school and the year gap). `motive_2nd` is the runner-up. `confidence` runs 1-5: 5 means the record settles it, 3 that I'd defend it, 1 that it's a judgment call I wouldn't. Social ties are capped at 2 by rule -- co-attendance isn't a relationship. `reasoning` is one or two sentences giving the pre-election basis for the call, so you can disagree with the logic rather than just the label. `search_used` and `source_1-5` flag the nine rows where I went outside the supplied data, with dated sources.
>
> **Two gaps.** Donations to the Speaker, Majority Leader and Budget chair have nowhere to go and fell to incumbent -- the label understates them. And four observations were unclassifiable because the firm identity is missing from the sample.
>
> Devin

Fair on Appropriations -- it isn't a defect in the Stewart-Woon data, which is standing-committee data by design. Restated plainly.

--- AUTHOR [2026-07-29 06:46:54] ----------
OK. Stefan is happy about the classification results. Let's continue doing the same classification for the rest 800 observations.

--- AGENT [2026-07-29 06:47:10] ----------
Let me set up for the remaining 800 -- the readable view plus the social-tie screen up front, since that's mechanical.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python - ↪ <<'PY' import pandas as pd, re P='2026.07 AI - Political Donati

--- AGENT [2026-07-29 06:47:48] ----------
24 observations have social-tie candidates. Two look strong -- Tenet Healthcare and Salesforce both match through their **government-relations VPs**, which is exactly the channel we kept that role for.

Now the readable view for classification:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && python - <<'PY' import pandas as
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && sed -n '121,400p' .rest_view.txt
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && sed -n '401,680p' .rest_view.txt

--- AGENT [2026-07-29 06:48:53] ----------
Understood -- starting at 201 and merging the first 200 back at the end. Reading the remainder:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && sed -n '681,1000p' .rest_view.txt
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && sed -n '1001,1300p' .rest_view.tx
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && sed -n '1301,1600p' .rest_view.tx

```
--- AGENT   [2026-07-29 06:49:40] ----------------------------------------
All 800 read. Now writing the classifications -- first half:
      [action] Write: C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-Universit⌋
      ↪  y-PhD-research-projects-2026-07-AI---Political-Donation-Motive

--- AGENT   [2026-07-29 06:52:42] ----------------------------------------
Now the second half:
      [action] Write: C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-Universit⌋
      ↪  y-PhD-research-projects-2026-07-AI---Political-Donation-Motive
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python - <<'PY' import sys, panda

--- AGENT   [2026-07-29 06:56:03] ----------------------------------------
Now merging with the first 200 into the complete sample:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python - <<'PY' import pandas as
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk" && ls *20260728* *first200*

--- AGENT   [2026-07-29 06:56:38] ----------------------------------------
The pilot file was renamed -- using it:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python - <<'PY' import pandas as
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && rm -f .tmp_rest.csv .rest_view.tx

--- AGENT   [2026-07-29 06:57:41] ----------------------------------------
All 1,000 classified -- `AI Talk/random_1000_house_firm_cand_cycle_don_20260729_claude-opus-5.csv`.

| Motive | n | share |
|---|---|---|
| committee | 509 | 50.9% |
| incumbent_contestant | 416 | 41.6% |
| geography | 39 | 3.9% |
| others | 30 | 3.0% |
| social_ties | 6 | 0.6% |

Mean confidence 3.56, no unlabelled rows. The first 200 were carried over unchanged and the merge verified on
`gvkey x cand_id x cycle` before writing.

## The gate holds

**34.8% of labels are not recoverable** from the 12 mechanical cells -- a lookup gets 65.2% against a 50.9%
modal baseline. Of the 896 rows where the candidate held a committee seat, `committee` was assigned to
**56.8%**.

That's higher than the pilot's 48.8%, and the reason is substantive rather than drift: the later cycles carry
more Energy and Commerce, Financial Services and Ways and Means members, whose jurisdiction maps onto
Compustat industries far more often than Rules or Ethics do. The 2000-2004 rows the pilot covered were
unusually thick with committees that touch nothing a public firm does.

## Three things worth knowing

**Social ties added only two, and both landed where the taxonomy predicted.** The screen found 29
institution-plus-year matches across 24 observations, but 22 were outranked by committee or geography. The
two promoted both run through a **government-affairs VP** -- Tenet Healthcare -> Altmire (George Washington,
4 years) and Salesforce -> Lieu (Georgetown Law, 2 years). That's the role you and I argued about keeping
when the subordinate filter was silently deleting all 511 of them. It's the only place in 1,000 observations
where category 4 fires on its own merits.

**Others is 3.0%, almost entirely the 27 gvkeys with no company name or GICS code.** Two of those were still
classifiable as geography, because the HQ district matched the candidate's seat even though the firm is
unnamed.

**Ways and Means is the line most likely to move under human coding.** I credited it more often in the later
cycles than the pilot's rule implied -- energy tax credits, Medicare Part D, remote sales tax -- because in
those situations the stake is specific rather than the generic corporate-tax exposure every firm has. A
different coder would draw that boundary elsewhere, and the blind 200 will show by how much.
```

```
Both runs are documented in `Guidance/_runlog.md` with conditions, deviations, and gate results.

--- AUTHOR  [2026-07-29 15:03:31] ----------------------------------------
Since GVKEY is unique and dones't change, I think we can supplement the gvkeys with no company name with
company name. I understand the GICS information may not be there if a firm becomes and has not been unlisted,
but maybe we can use their most recent available GICS in that case. What do you think?

--- AGENT   [2026-07-29 15:03:51] ----------------------------------------
Agreed, and the reasoning is sound -- gvkey is permanent, so a missing name is a merge gap rather than a fact
about the firm. Let me check what's recoverable:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -
      ↪  <<'PY' import pandas as pd P='2026.07 AI - Political Donation M

--- AGENT   [2026-07-29 15:04:47] ----------------------------------------
All 29 are recoverable -- and the pattern is informative: **every one has GICS data ending the year before
its donation cycle.** These are firms acquired or delisted mid-cycle. Aetna's data stops in 2017 and the
donation is 2018; TRW stops in 2001 and the donation is 2002.

That makes the fix clean, because carrying *forward* from the last prior year uses no post-cutoff information.
      [action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk/2.add_committee_fields_and_classi
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -

--- AGENT   [2026-07-29 15:05:40] ----------------------------------------
`\202` was read as an octal escape and became U+0082. Fixing at the byte level -- and I'll stop using Python
literals for Windows paths:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk" && python -c " import io p='
      [action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research
      ↪  projects\2026.07 AI - Political Donation Motive\AI Talk"; $p = Start-Proces

--- AGENT   [2026-07-29 15:06:05] ----------------------------------------
All 31 rows backfilled, none left missing. Now reclassifying those rows with the firms identified:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python -c " import pandas as pd d
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python - <<'PY' import pandas as
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python -c " import pandas as pd d

--- AGENT   [2026-07-29 15:07:39] ----------------------------------------
One error of mine to correct: row 721 is **United Parks & Resorts** (SeaWorld) -- it had a name and industry
all along, and I wrongly labelled it "insufficient information" when writing the batch.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python - <<'PY' import pandas as

--- AGENT   [2026-07-29 15:08:12] ----------------------------------------
Good call -- the backfill worked, and it turned up an error of mine along the way.

## Complete sample, all 1,000

| Motive | n | share |
|---|---|---|
| committee | 524 | 52.4% |
| incumbent_contestant | 431 | 43.1% |
| geography | 39 | 3.9% |
| social_ties | 6 | 0.6% |
| **others** | **0** | **0.0%** |

Mean confidence 3.64. **No observation is unclassifiable.**
```

What the backfill found

Your diagnosis was exactly right, and the data confirms it sharply: **every one of the 29 gvkeys had GICS data ending the year before its donation cycle.** Aetna stops in 2017 against a 2018 donation; TRW stops in 2001 against 2002. These are firms acquired or delisted mid-cycle -- the donation happened while they were still listed, and they dropped out of Compustat that same year.

That makes the carry-forward clean rather than a compromise. Script 2 now constrains it to `bf_year <= cycle`, so a later vintage can never enter, and records `firm_info_carried_fwd` and `firm_info_year` so the substitution is visible.

Reclassifying with the firms named changed several substantively: **TRW -> Weldon** becomes Armed Services (space and defence systems), **Aetna -> Dingell** becomes Energy and Commerce, **United Airlines -> Costello** becomes Transportation, **IMS Health -> Murphy** becomes Energy and Commerce, and two became geography once the HQ district could be read against the seat.

One error of mine

The last row in `others` was **United Parks & Resorts** (SeaWorld) -> Susan Davis, and it was never missing anything -- the sample carried both the name and the GICS code. I mislabelled it "insufficient information" while writing the batch. Corrected to incumbent/contestant, with the correction noted in its reasoning field so the record shows what happened.

Gate, final

12 mechanical cells reproduce 67.0% of labels against a 52.4% baseline -- **33.0% not mechanically recoverable**. Committee is assigned to 58.5% of the 896 rows where the candidate held a seat.

The gate figure drifted down from the pilot's 40.5% as the sample filled out, which is worth knowing rather than glossing: the margin narrows because `committee` and `incumbent_contestant` together now cover 95% of observations, so the modal baseline is stronger. The jurisdiction judgment is still doing the work -- it's just being measured against a tougher benchmark.

Everything is in `Guidance/_runlog.md` with both runs and the amendment.

--- AUTHOR [2026-07-29 15:10:16] ----------
Can you give a similar overview of the classificaiton of total 800 observations like what you did you in the last run?

--- AUTHOR [2026-07-29 15:10:39] ----------
Can you give a similar overview of the classificaiton of total 800 observations like what you did you in the second last run?
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && python -c " import pandas as pd d
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && python -c " import pandas as pd d

--- AGENT [2026-07-29 15:11:40] ----------
Numbers check out, and one of them is reassuring. Here's the text:

> Stefan -- the remaining 800 are done and merged, so the file now covers all 1,000. Method unchanged from the pilot; a few things worth flagging.
>
> **Committee rose from 50% to 60% of candidates holding a seat.** That looked like drift until I checked the sample: powerful candidates nearly double in the later cycles (8% to 15.5%), and the share holding any seat rises too. The later cycles are simply thicker with Energy and Commerce, Financial Services and Ways and Means members, whose jurisdiction maps onto Compustat industries far more often than Rules or Ethics do. The 2000-2004 rows the pilot happened to cover were unusually full of committees that touch nothing a public firm does.
>
> **Geography rose from 1.5% to 4.5%, and this one is not a judgment call at all** -- it tracks the district-match rate in the underlying data exactly, 1.5% against 4.5%. The category is doing nothing but reporting what the HQ mapping says.

```
>
> **Social ties stayed almost empty: two more, six in total.** Both new ones run through a government-affairs
VP -- Tenet Healthcare with Jason Altmire (George Washington, four years apart) and Salesforce with Ted Lieu
(Georgetown Law, two years). That is the one role we deliberately kept in the executive roster despite it
sitting below the C-suite, and it turns out to be the only place in 1,000 observations where the category
fires on its own merits. Everything else that matched on school was outranked by committee or geography.
>
> **One data fix worth knowing about.** 31 rows had no company name or industry, which I had been treating as
unclassifiable. Devin pointed out that gvkey is permanent, so a blank name is a merge gap rather than a fact
about the firm -- and every one of those firms turned out to have data ending the year *before* its donation
cycle, because they were acquired or delisted mid-cycle. Aetna's record stops in 2017 against a 2018
donation. Carrying the last prior observation forward recovered all 31 (and only forward, so nothing
post-election enters). Several changed substantively: TRW became Armed Services, Aetna became Energy and
Commerce, United Airlines became Transportation. **Nothing now sits in "Others."**
>
> I also corrected one row of my own -- United Parks was labelled "insufficient information" when the sample
had identified it all along.
>
> **On the gate:** 33% of labels are still not reproducible from the mechanical indicators, down from 40.5%
in the pilot. The judgment did not weaken -- the benchmark got harder, because committee and incumbent
together now cover 95% of the sample, so guessing the modal category alone gets you further.
>
> Devin

One note for you rather than the email: I've written it in your voice referring to yourself in the third
person for the data-fix credit. Swap that to "I pointed out" if you'd rather, or drop the attribution
entirely.

--- AUTHOR  [2026-07-29 15:15:14] ----------------------------------------
What does "not reproducible" in "33% of labels are still not reproducible from the mechanical indicators"
mean?

--- AGENT   [2026-07-29 15:15:30] ----------------------------------------
It's the answer to a specific question: **if you knew only a handful of binary facts already in the data, how
much of my labelling could you regenerate without me?**

Let me show you the actual mechanics:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python -c " import pandas as pd d

--- AGENT   [2026-07-29 15:15:59] ----------------------------------------
Concretely: the five indicators sort all 1,000 observations into 12 distinct cells. For each cell I take the
**most common motive in that cell** and use it as the prediction for every row in it. That prediction gets
670 right and **330 wrong** -- those 330 are what "not reproducible" means.

Look at where the misses live. Four cells carry all of them, and the largest is stark:

**604 observations** share the profile *no district match, no state match, incumbent, holds a committee seat,
not powerful*. On those five facts they are indistinguishable. But I labelled **384 committee and 220
incumbent** -- because Energy and Commerce for a utility is jurisdiction, while Rules for a title insurer is
not. The mechanical rule can't see that distinction; it's the firm-to-committee mapping, and it's the whole
point of the exercise.

The cells with zero misses are the ones where the indicators genuinely determine the answer -- a district
match always gives geography, no committee seat and no geography always gives incumbent. There, I add
nothing, and it would be dishonest to claim otherwise.

## Two things this number is not

**It's not accuracy.** It says nothing about whether my 524 committee labels are *right*. It says only that
they aren't a mechanical function of five variables. Human coding is what tests correctness.

**It's generous to the mechanical rule, which makes 33% a floor.** I let the lookup see the labels themselves
when picking each cell's modal answer -- it's fitted in-sample with the answer key. A rule built without that
would do worse, so the genuinely unrecoverable share is *at least* 33%.

**And the honest limit:** if I had labelled the rows at random, this number would be *higher*, because noise
is maximally unpredictable. So a large value alone isn't evidence of quality -- it only rules out the
specific failure of the model being an expensive lookup table. It's a necessary condition, not a sufficient
one.
```

```
For the email, I'd phrase it as: *"On 330 of the 1,000 observations, the assigned motive differs from what
you would predict from district match, state match, incumbency, committee membership and leadership alone --
almost all of them cases where a candidate sits on a committee that has no bearing on that particular firm."*
That says what was measured without implying it measures correctness.

Can you save your answer in the last two runs in a md file in the \AI Talk folder and also make few slides on
them in trial_sample.tex?
      [action] Write: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk/classification_overview.md

--- AGENT   [2026-07-29 15:25:05] ----------------------------------------
Now the slides:
      [action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk/Slide/trial_sample.tex
      [action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research
      ↪  projects\2026.07 AI - Political Donation Motive\AI Talk\Slide"; $pdflatex =
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk/Slide" && PYTHONIOENCODING=ut
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && git add -A && git commit -q -F -

--- AGENT   [2026-07-29 15:26:27] ----------------------------------------
Both done.

## `AI Talk/classification_overview.md`

Seven sections, written for someone who already knows the sample and categories: how the classification ran
and why the priority order deviates from numeric; the results with the pilot-versus-remainder comparison; the
committee jurisdiction test and the two under-inclusive lines; social ties and the five-year cut; the
firm-identity backfill; how to read each output column; and the gate with its full cell table and limitations.

One thing the memo makes clearer than the email did -- the pilot/remainder differences are **not** classifier
drift. Geography tracks the district-match rate in the data exactly (1.5% vs 4.5% in both), and the committee
rise comes with a doubling of powerful candidates and more seat-holders in the later cycles.

## Two new slides -- deck now 7 pages, zero overfull boxes

**"Assigning a Motive to Each Donation"** -- the priority order with the reason it isn't numeric, the
distribution, and the finding that holding a seat isn't having jurisdiction. The line that lands: *a "holds a
committee seat" dummy would be wrong 41% of the time.*

**"Does the Model Add Anything a Lookup Table Could Not?"** -- the gate laid out cell by cell. This one
carries the talk, because the table shows its own answer: all disagreement sits in four cells, and the
largest holds **604 observations identical on all five indicators** yet split 384 committee / 220 not. The
cells where the indicators do determine the answer show zero disagreement, which is the honest half -- there
the model adds nothing.

Both source notes state the limitation rather than burying it: the lookup is fitted in-sample so 33% is a
floor, and the gate measures whether labels are *mechanical*, not whether they're *correct* -- random labels
would score higher still.

That last point is worth having on the slide rather than only in the memo. If someone in the room asks "so
the AI is 33% better?", the note answers before you have to.

--- AUTHOR  [2026-07-29 15:32:52] ----------------------------------------
On page 6 of the slide, the column used the word of "Wrong". Could this make audiance misinterpret what we
mean? Should we use a better word? Also readers may not understand what "12 distinct cells" means here? We
may have a similar issue on this part "District match 39 geography 0
No seat, no geographic link 94 incumbent 0" as well. I think we should update this page to make it more
understandable and accessible to the audiance?

--- AGENT   [2026-07-29 15:33:24] ----------------------------------------
All three are fair criticisms, and the first is the serious one -- "Wrong" reads as *our labels are wrong*,
```

```
when it means *the shortcut's guess differs from ours*. Let me verify the group arithmetic before rewriting:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python -c " import pandas as pd d

--- AGENT   [2026-07-29 15:33:49] ----------------------------------------
Much cleaner than the 12-cell table -- **all 330 misses sit in a single group.** Rewriting:
      [action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk/Slide/trial_sample.tex
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk/Slide" && grep -q "usepackage
      [action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research
      ↪  projects\2026.07 AI - Political Donation Motive\AI Talk\Slide"; & "C:\Users

      ↪  Political Donation Motive" && PYTHONIOENCODING=utf-8 python -c

--- AGENT   [2026-07-29 15:37:05] ----------------------------------------
Slide renders correctly. Now aligning the memo's gate section to match:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk" && python - <<'PY' import io

--- AGENT   [2026-07-29 15:37:36] ----------------------------------------
The memo was renamed to your convention -- updating it there:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk" && ls *.md && python - <<'PY
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && sed -n '/## 7\./,$p' "AI Talk/cla

--- AGENT   [2026-07-29 15:38:33] ----------------------------------------
All three problems fixed, and the last one turned out to improve the slide rather than just clarify it.

## "Wrong" -> "Cases it cannot explain"

You were right that this was the dangerous one. "Wrong" reads as *our labels are wrong*, when it means *the
shortcut's guess differs from ours*. An audience member could reasonably have taken the slide as reporting a
33% error rate.

## "12 distinct cells" -> the five questions in plain words

The slide now opens with them as questions -- *HQ in the candidate's district? Same state? Incumbent? Holds a
committee seat? A chair or party leader?* -- and explains that donations answering all five alike are
indistinguishable to any rule built from them.

## The bottom rows -- and this is where it got better
```

You spotted that those two rows were in a different format from the top four, which was true. Fixing it meant collapsing the twelve patterns into readable groups, and **the story turns out to be much simpler than the twelve-row table suggested**:

What the five answers say	Donations	The rule guesses	Cases it cannot explain
HQ sits in the candidate's district	39	geography	0
No committee seat, or not an incumbent	96	incumbent	0
An incumbent holding a committee seat	**865**	**committee**	**330**

Every one of the 330 sits in a single group. Those 865 donations are all incumbents holding a seat with no home-district link -- identical on all five answers, so any rule must give them one label. We split them 524 committee / 341 not.

The three-row version says in one glance what the twelve-row version buried: the exercise lives entirely in one question, *does this committee matter to this firm?*

It also makes the honest half easier to say out loud. The slide now states plainly that where the five answers settle the question, **the model adds nothing and we should not claim credit** -- 39 geography cases and 96 generic-access cases, zero disagreement in both.

Deck is 7 pages, zero overfull boxes. The memo's gate section now uses the same three groups and the same wording, so the two don't drift apart.

--- AUTHOR [2026-07-29 15:47:17] ----------
I think the page 7 should be more about how much the results are very reproducible and how much not and explain why those miight have different classifications with a different model. The 330 and some breakdowns are for explaining the reasons and logic behind to hele the audiance better understand the help and boundary of help by LLMs? We don't want bury the audiance with the details before they understand a big picture?

--- AGENT [2026-07-29 15:47:45] ----------
That's the right criticism -- the slide currently leads with mechanism and makes the audience assemble the point. Restructuring so the headline is the split itself, with the 330 as supporting evidence:
[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/AI Talk/Slide/trial_sample.tex
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/AI Talk/Slide" && grep -n "Could a Si
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/AI Talk/Slide" && sed -n '266,310p' t

--- AGENT [2026-07-29 15:48:49] ----------
Let me replace by line range instead of string matching:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/AI Talk/Slide" && python - <<'PY' imp
[action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation Motive\AI Talk\Slide"; & "C:\Users
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/AI Talk/Slide" && grep -B2 -A4 "Undef
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/AI Talk/Slide" && grep -n "shortstack

--- AGENT [2026-07-29 15:50:00] ----------
Backslashes were collapsed. Let me check the whole frame and repair:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/AI Talk/Slide" && awk 'NR>=268 && NR<
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/AI Talk/Slide" && python - <<'PY' imp
[action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation Motive\AI Talk\Slide"; & "C:\Users
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && PYTHONIOENCODING=utf-8 python -c
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && git add -A && git commit -q -F -

--- AGENT [2026-07-29 15:51:19] ----------
Restructured -- the slide now hands over the point before asking for any work.

What changed

```
**Retitled "How Much of This Would Any Model Reproduce?"** and it opens with the answer rather than the
method:

> **Two thirds of the labels are settled by the data itself.** 670 of 1,000 follow from facts already in the
sample -- any careful classifier lands in the same place.
>
> **The other 330 rest on a single judgement, and could move.** A different model, or a different human
coder, could reasonably label these otherwise. They mark the boundary of what the exercise can claim.

The table and the 865-observation group are now *evidence for* that claim rather than the claim itself. The
column reads "Open to judgement" rather than "Wrong."

## The addition you asked for

The closing bullet now answers *why* a different model would differ, by naming the three specific lines
rather than gesturing at "judgment":

- **How broadly to read Energy and Commerce** -- it spans telecom, energy, health and consumer goods, so its
reach across the sample is a choice
- **Whether Ways and Means counts**, since the tax code touches every firm
- **Whether Appropriations counts**, since it works through subcommittees the data doesn't record

Those are the three places I actually had to draw a line while classifying, and they're where a rerun would
diverge. That gives the audience something concrete to hold instead of an abstract claim about model variance.

## One compile note

The frame briefly broke because a Python rewrite collapsed `\\` to `\` in the tabular -- the row terminators
and the `\shortstack`. Repaired at byte level; five sites. Deck is 7 pages, zero overfull boxes.

The memo's gate section still uses the older framing, which is fine -- a document can afford the
mechanism-first order that a slide can't. Say the word if you'd rather they match.

--- AUTHOR  [2026-07-29 18:37:10] ----------------------------------------
I'm thinking about one version 2 taxonomy that improves the classification and says more about the
incumbent_contestant category. Do you have a good idea?

--- AGENT   [2026-07-29 18:37:51] ----------------------------------------
Let me look at what's actually inside that bucket before proposing anything.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python -c " import pandas as pd d

--- AGENT   [2026-07-29 18:38:33] ----------------------------------------
The data makes the case on its own. Let me check one more thing before recommending:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python -c " import pandas as pd d

--- AGENT   [2026-07-29 18:39:20] ----------------------------------------
Yes, and the data points to a specific one -- plus it rules out the alternative I expected to prefer.

## The idea: split `incumbent_contestant` three ways

| Proposed category | n | median $ | repeat rate |
|---|---|---|---|
| **Leadership access** -- chamber leader, or chair/ranking of *any* committee | 54 | $2,000 | **35%** |
| **Incumbent access** -- rank-and-file sitting member | 292 | $1,500 | 20% |
| **Electoral investment** -- challenger or open seat | 85 | $1,000 | **1%** |

The separation is clean, and it shows up in variables I did **not** use to define the split. Donation size
falls monotonically, and relationship persistence collapses from 35% to 1%. These are three different
behaviours currently averaged into one number.

The striking row is the first. **Leadership donations look like committee donations, not like generic
access** -- same $2,000 median, and a *higher* repeat rate than committee donations (35% vs 26%). Firms treat
access to the Speaker or a whip the way they treat access to a relevant committee: a relationship worth
sustaining. Calling that "generic incumbent access" throws the distinction away.

The last row matters for the opposite reason. A 1% repeat rate means challenger donations are essentially
one-shot. They cannot be relationship maintenance, and they cannot be access -- the candidate holds nothing.
Whatever they are, they aren't what the other 346 are.
```

What I checked and would *not* do

I expected to also recommend splitting `committee` by whether the candidate chairs the relevant committee or merely sits on it. **The data says don't:** $2,250 vs $2,000 median, and identical 26% repeat rates. There's no behavioural daylight, so it would be a category that costs interpretive complexity and buys nothing.

That's worth knowing because it *refines* rather than contradicts your earlier decision that leadership is a field. The coherent position: **leadership is an intensity modifier when jurisdiction exists, and a motive in its own right when it doesn't.** Chairing Ways and Means while a firm has a tax stake is still a committee donation. Being Majority Whip with no jurisdictional link at all is something else -- and right now that something else has nowhere to go.

Why this is the right v2 move

It costs nothing -- `cand_power_l1` and `cand_ici` are already built, so no new data and no re-derivation. It shrinks the residual from 43% to 29%. And for the outcome analysis it gives you three groups with genuinely different predicted returns: agenda access, generic insurance, and a bet contingent on someone winning.

One thing it does not fix

`Incumbent access` is still defined by absence -- not geography, not committee, not a tie, not leadership. Splitting a residual makes it smaller and more interpretable; it doesn't make it positive. The 292 remain "we found no firm-specific reason."

The real fix for that is the ideology category you deferred, together with the firm partisan-tilt variable it needs. If a firm gives one-sidedly across many candidates, a rank-and-file donation to a co-partisan stops being unexplained. I'd treat that as v3 rather than folding it into v2, so you can see what the three-way split does on its own first.

One caveat to record: the 1% challenger repeat rate is partly mechanical, since challengers rarely recur as candidates. The donation-size gap isn't.

--- AUTHOR [2026-07-29 18:49:59] ----------
1. Can I understand your proposed split as incumbent_leader, incumbent_access, and contestant_investment? 2. Do I also need to improve other categories for better classification results, or we mainly need to split incumbent_contestant category? Obviously I don't want to have so many categories to get people lost in the category jungle, so it's ok if you think we only need small adjustment to our current taxonomy

--- AGENT [2026-07-29 18:50:39] ----------
Yes -- and your names are better than mine, because they make the parent-child structure visible:

v2 category	v1 equivalent	n
`incumbent_leader`	incumbent_contestant	54
`incumbent_access`	incumbent_contestant	292
`contestant_investment`	incumbent_contestant	85

One thing to pin down in the definition: `incumbent_leader` should cover **committee chairs and ranking members as well as chamber leadership** -- it's `cand_power_l1 = 1`, not just Speaker/whips. The name reads narrower than the rule, so the taxonomy file should say so explicitly.

Also note the split absorbs one of your earlier decisions: incumbent-versus-contestant was recorded as a *field* because the two were economically opposite. Under v2 that distinction becomes a category boundary, so the field is redundant for that purpose -- though `cand_ici` still usefully separates challengers from open seats, which the category collapses.

No, the other categories don't need splitting

I went through each:

Geography (39) works exactly as designed -- it tracks the district match and adds nothing beyond it, which is the honest outcome. Its limitation is that we only see headquarters, not plants. That's a data problem, not a category problem.

Committee (524) is the big one, and I already tested the obvious split -- chair versus member -- and it produced nothing: $2,250 vs $2,000 median, identical repeat rates. Splitting by *which* committee isn't a motive distinction either; `motive_detail` already names the committee, so you can cut on it in analysis without another category.

Social ties (6) and **Others (0)** are too small to divide. Keep both -- social ties because it cost two datasets to build and is theoretically central, Others as a safety valve the full sample will eventually need.

So v2 is one change, and it takes you from 5 categories to 7. That's the upper edge of comfortable, but three of the seven are tiny, so the working taxonomy is really four.

The thing that would improve classification isn't a category

Worth separating two goals. More categories improve *resolution* -- what the labels can tell you. They don't improve *accuracy*.

All 330 contestable cases turn on one question: does this committee cover this firm? The two weakest points there are the ones I flagged when classifying:

- **Ways and Means** -- the tax code touches every firm, so I credited it only for distinctive stakes. That line is mine, not the taxonomy's.
- **Appropriations** -- it works through subcommittees the data doesn't record, so I credited it only where the firm clearly sells into federal programmes.

Writing those two rules explicitly into the v2 prompt -- with worked examples of what counts and what doesn't -- would do more for classification quality than any new category. It also makes the exercise more reproducible, since a second model would inherit the rule rather than reinvent it.

And I'd hold ideology for v3

Adding it now would make eight categories and confound two changes at once. Run the split first; if `incumbent_access` stays large and undifferentiated at 292, that's the evidence for adding ideology -- and the firm partisan-tilt variable it needs -- as a separate step.

--- AUTHOR [2026-07-29 18:58:12] ----------
1. I agree and think incumbent_leader should be better called incumbent_powerful. 2. I agree with your handling with "Ways and Means" and "Appropriations" committees. 3. I agree that we can try the v2 taxonomy, look at the result of incumbent_access before deciding if we should add ideology. But before we try it, I want to confirm one thing: now that we that have incumbent_powerful and Committee, what should be priority order. I think we should make it clear before trying it.

--- AGENT [2026-07-29 18:58:32] ----------
Good question to settle first -- it's the one place where v2 could quietly change what v1 already decided. Let me check one edge case:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && python -c " import pandas as pd d

--- AGENT [2026-07-29 18:59:17] ----------
`incumbent_powerful` is the better name -- it matches `cand_power_l1`, which is what the rule actually keys on.

The priority order

Firm-relational categories first, exactly as in v1:

1. **Geography** -- HQ district match
2. **Committee** -- jurisdiction over *this* firm
3. **Social ties**
4. *then the fallback block*
5. **Others**

Committee outranks `incumbent_powerful`, which preserves your earlier decision unchanged: *the category records why the donation was made, the field records who the candidate was.* Bill Young chairing Appropriations while Triumph supplies aerospace parts stays `committee`, with `cand_power_l1 = 1` alongside it.

`incumbent_powerful` fires only when the candidate holds power but **nothing firm-specific explains the donation**. In the current sample that's the honest minority: of 140 powerful candidates, 83 are already explained by committee, 2 by geography, 1 by a social tie. Only **54 (39%)** would become `incumbent_powerful`.

The fallback block needs no internal ordering

This is the part worth being precise about: the three new categories are a **partition, not a priority sequence**. They cannot conflict, because they're defined on mutually exclusive conditions --

	condition
`incumbent_powerful`	`cand_power_l1 = 1`
`incumbent_access`	incumbent, `cand_power_l1 = 0`
`contestant_investment`	not an incumbent

and I confirmed the data cooperates: **zero non-incumbents are powerful**, so there's no candidate who could fall into two of them. The priority list only has to place the block; inside it, the assignment is deterministic.

(Two non-incumbents do hold a committee seat -- sitting members contesting a different seat. They need no special rule: if the committee has jurisdiction they're `committee`, otherwise `contestant_investment`.)

One practical consequence worth knowing

Because committee, geography and social ties all keep their v1 meanings, **v2 can be derived from the existing labels mechanically** -- split the 431 `incumbent_contestant` rows on two columns already in the file. No reclassification, no rerun, no tokens.

That gives you the v2 distribution immediately, which is all you need to judge whether `incumbent_access` at 292 is still too large and undifferentiated to leave alone.

The caveat: a *fresh* v2 run isn't guaranteed to match the derived version exactly. A model told up front that `incumbent_powerful` exists might push a borderline committee case into it -- the categories on offer shape marginal calls. So the derived version is right for the decision about ideology, but if v2 becomes the taxonomy of record, it should be produced by an actual run.

Want me to derive it now so you can see where `incumbent_access` lands?

--- AUTHOR [2026-07-29 19:03:45] ----------
1. Let's record our v2 classification in taxonomy_decisions.md and create the classification_prompt_v2.md. I want the classification_prompt_v2.md looks like we run the classification from the start because I may apply it to my full sample. Also I think we can include cand_power_l1 = 1 as poweful as well because retired speaker can still be very power. 2. But for this analysis, I agree with you that we can preserve what we have got and only split the 431 incumbent_contestant rows.

--- AGENT [2026-07-29 19:04:05] ----------
Let me check the "retired Speaker" point empirically, since it's buildable and changes the category:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python - ↪ <<'PY' import pandas as pd P='2026.07 AI - Political Donation M

--- AGENT [2026-07-29 19:04:42] ----------
Only **4 rows** in the residual are formerly-but-not-currently powerful -- and their median donation is $1,000, *below* both the currently-powerful ($2,000) and the never-powerful ($1,500). Let me derive v2 and then explain what I'd do with that.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && python - <<'PY' import pandas as

--- AGENT [2026-07-29 19:05:22] ----------
Your clarification lands on a distinction worth separating, because the two readings have different answers.

If you mean chairs and ranking members count alongside Speaker/whips -- yes, that is already the rule. `cand_power_l1 = 1` covers all of them, which is why a former Speaker now chairing a committee stays powerful.

If you mean someone with no current post at all -- I built that variable and checked. Only 4 of the 431 residual rows are formerly-but-not-currently powerful, and their median donation is **$1,000**, below both the currently powerful ($2,000) and the never powerful ($1,500). The conceptual case points the same way: what a PAC buys from the Speaker is the ability to schedule or block a bill, and a former Speaker cannot do that. I'd keep them in `incumbent_access` and record `cand_ever_power_l1` as a field so the question stays testable at full-sample scale.

v2 derived -- `AI Talk/..._v2.csv`

Category	n	share
committee	524	52.4%
incumbent_access	**292**	**29.2%**
contestant_investment	85	8.5%
incumbent_powerful	54	5.4%

```
| geography | 39 | 3.9% |
| social_ties | 6 | 0.6% |

The three new categories separate on variables that played no part in defining them:

| | median $ | repeat | state match |
|---|---|---|---|
| incumbent_powerful | $2,000 | **35%** | 30% |
| incumbent_access | $1,500 | 20% | 22% |
| contestant_investment | $1,000 | **1%** | 28% |
| *committee (reference)* | *$2,000* | *26%* | *13%* |

Now the documents:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/Guidance" && python - <<'PY' import i

--- AGENT   [2026-07-29 19:06:06] ----------------------------------------
Now the standalone v2 prompt:
      [action] Write: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/Guidance/classification_prompt_v2.md

--- AGENT   [2026-07-29 19:07:11] ----------------------------------------
Agreed and done -- the split is already derived. Let me add the `cand_ever_power_l1` field to the build
script so it's reproducible, then finalise:
      [action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk/2.add_committee_fields_and_classi
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk" && python - <<'PY' import io
      [action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research
      ↪  projects\2026.07 AI - Political Donation Motive\AI Talk"; $p = Start-Proces
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python - <<'PY' import pandas as
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && cat >> Guidance/_runlog.md <<'EOF

--- AGENT   [2026-07-29 19:08:52] ----------------------------------------
v2 is recorded and derived.

## `AI Talk/random_1000_house_firm_cand_cycle_don_20260729_claude-opus-5_v2.csv`

| Category | n | share |
|---|---|---|
| committee | 524 | 52.4% |
| **incumbent_access** | **292** | **29.2%** |
| contestant_investment | 85 | 8.5% |
| incumbent_powerful | 54 | 5.4% |
| geography | 39 | 3.9% |
| social_ties | 6 | 0.6% |

`motive_v1` is retained alongside `motive`, so every split is traceable back to its v1 label.

## `classification_prompt_v2.md` -- written for a fresh full-sample run

Self-contained, assuming no knowledge of earlier rounds. Two things in it are new rather than carried over:

**The two committee lines are now rules with tables rather than my judgment.** Ways and Means requires a
*distinctive* stake -- excise, tariffs, Medicare payment, retirement products, targeted credits -- with an
explicit "do not credit" column for ordinary corporate tax. Appropriations requires federal money the firm
actually receives. And because Energy and Commerce spans telecom, energy, FDA, Medicaid, consumer protection
and environment, the prompt now requires naming *which strand* applies in `motive_detail`.

That matters for the full sample: those rules were in my head during this run, so a rerun without them would
diverge.

**Category 4 has an explicit "power means power now" clause**, which is where your retired-Speaker point
landed.

## On that point
```

`cand_ever_power_l1` is now built in script 2 -- 159 rows ever held a senior-party post, 19 hold none currently, and **4 of those sit in `incumbent_access`**. Recorded as a field, not a category, so it stays testable at full-sample scale where the count will be larger and the question actually answerable.

One caveat worth carrying forward

This file is **derived, not reclassified**. That's the right call for the decision it serves -- whether `incumbent_access` at 29.2% needs ideology added -- because the split uses only columns already in the data.

But a model told up front that `incumbent_powerful` exists might push a borderline committee case into it; the categories on offer shape marginal calls. So if v2 becomes the taxonomy of record for the paper, it should be produced by an actual run against `classification_prompt_v2.md` rather than inherited from this derivation. That's noted in the runlog.

`incumbent_access` is still the second-largest category and still defined by absence -- which is precisely the v3 question you wanted to see first.

--- AUTHOR [2026-07-29 19:18:57] ----------
I want to confirm one thing: you use `cand_power_l1` = 1 as a condition for Incumbent_powerful. Assuming it's 2011 year and 2012 Novmber will be a new cycle. Does `cand_power_l1` = 1 mean the candidate holds a powerful position between 2011 Jan to 2013 Jan or between 2009 Jan and 2011 Jan? I though "l1" means lag? I just want to confirm it. I thought when we mean powerful candidate, we meant the candidate holds a powerful position as of the election date, right?

--- AGENT [2026-07-29 19:19:27] ----------
Important question, and checking it turned up a real problem -- not with the data, but with the name I gave it.

[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -c "
↪ import pandas as pd c=pd.read_stata('1.Common Dataset/Politi

--- AGENT [2026-07-29 19:20:08] ----------
Verified, and the answer is **the first one**: for a 2012-cycle observation, `cand_power_l1 = 1` means the candidate holds the position **January 2011 - January 2013** -- the Congress sitting throughout the donation window and on election day. That is what you wanted.

The proof is Dave Camp. He shows as **Ways and Means chair** for the 2012 cycle. He became chair in January 2011 with the 112th Congress; in the 111th (2009-2011) he was only ranking member. So the field is reading the 112th, not the 110th or 111th.

But the name is wrong, and that's my error

`_l1` implies a lag relative to the donation. **There isn't one.** The `+2` shift in the build script corrects for something else entirely: the Stewart-Woon file labels each Congress by *the election that produced it*, so the 112th Congress is filed under "cycle 2010." Shifting by two undoes that convention and lands on the contemporaneous Congress.

Committee file labels the 112th Congress as	cycle 2010
The 112th actually sits	Jan 2011 - Jan 2013
Donation cycle 2012 covers	Jan 2011 - Nov 2012
So the roster is	**contemporaneous, not lagged**

Had I merged on cycle directly, a 2012 observation would have picked up the **113th** Congress -- seated January 2013, after the election. That's the look-ahead bug the shift exists to prevent. The suffix records how the fix was implemented rather than what the variable means, which is exactly backwards for a variable name.

Proposed rename

Your instinct to question it is right, and a referee would ask the same thing. The names should say *sitting*, not *lagged*:

Now	Proposed
`cmte_l1`	`cmte_sitting`
`cand_power_l1`	`cand_power_sitting`
`cand_ever_power_l1`	`cand_ever_power`
`exec_roster_l1.csv`	`exec_roster_preelection.csv`
`Code/1.build_exec_roster_l1.py`	matching rename

```
The executive roster has the same problem -- it's built as of the day *before* the election, so it's also
contemporaneous, not lagged.

This touches the build script, both prompts, the taxonomy file, the memo, the slides and two filenames, so
I'd rather you confirm before I run it. The alternative is to keep the names and add a one-line definition
wherever they appear -- cheaper, but it leaves a trap for anyone reading the data without the documentation.

One precision caveat either way: the source gives one record per member-committee-Congress, so a mid-Congress
change -- someone taking a chair in the middle of a session -- isn't captured.

--- AUTHOR  [2026-07-29 19:27:33] ----------------------------------------
1. Is the reason that we can't name cand_power_l1 as cand_power to make the donation time consistent with
powerful positiin time that in each row, we also have the election result variables (e.g., cand_power for
that election cycle)? So it's just a way of data construction. Because we want to election results (including
committee assignment and leader position) be in row, the powerful candidate at the time of donation (i.e.,
before election date) will be coded as cand_power_l1. Is this understanding correct? If so, I think
cand_power_l1 is a correct variable name and our classification is ok.

--- AUTHOR  [2026-07-29 19:27:52] ----------------------------------------

cand_power_l1 is a correct variable name and our classification is ok.

--- AGENT   [2026-07-29 19:28:23] ----------------------------------------
Yes -- your reading is correct, and it makes my rename proposal wrong.

The convention is the source data's own: **the Stewart-Woon file indexes a Congress by the election that
produced it.** Under that indexing, for cycle 2012:

| | Congress | Period |
|---|---|---|
| `cand_power` (period *t*) | 113th, Jan 2013 - Jan 2015 | what the election **produced** -- an outcome
variable |
| `cand_power_l1` (period *t-1*) | 112th, Jan 2011 - Jan 2013 | sitting during the donation window --
**pre-determined** |

So once the dataset carries the election results in the same row -- which is the plan, since committee
assignment and leadership after the election are exactly the outcome variables -- the unsuffixed name is
already taken by the post-election object, and the pre-election one *is* the lag. `_l1` is not a description
of how the merge was done; it's the correct time index.

I was anchoring "contemporaneous" on the donation window. But the row is indexed by **election cycle**, and
the natural period-*t* object for a cycle is what the election produces. Under that indexing the sitting
Congress genuinely is *t-1*. Keeping the source file's convention also means anyone joining our data back to
Stewart-Woon uses the same index, which is worth more than a name that reads intuitively in isolation.

**So the names stay, and the classification is fine.** `incumbent_powerful` keys on power held during the
donation window through election day, which is what you specified.

One thing still worth fixing, cheaply: the convention is currently *inferable* rather than *stated*. Let me
write it down where it's used.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python - <<'PY' import io NOTE =

--- AGENT   [2026-07-29 19:28:51] ----------------------------------------
One cosmetic artefact from the insert -- a doubled separator:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/Guidance" && python -c " import io fo

--- AGENT   [2026-07-29 19:29:14] ----------------------------------------
Confirmed on both counts, and my rename proposal is withdrawn.

**Your reading is right.** Once the row carries the election results -- post-election committee assignment
and leadership, which are the outcome variables the second half regresses on -- the unsuffixed name is
already spoken for. `cand_power` would mean the Congress the election *produced*; `cand_power_l1` is then
correctly the one sitting while the donation was made. The suffix is a time index, not a merge artefact.
```

Renaming to `_sitting` would have been worse in two ways: it breaks the correspondence with the source data, and it frees a name that the outcome variables need.

The classification is fine. `incumbent_powerful` keys on power held during the donation window through election day, which is what you specified.

What I changed

Only documentation. The convention was inferable but never stated, so both `taxonomy_decisions.md` and `classification_prompt_v2.md` now carry a short section spelling it out -- the period-*t* / period-*t-1* logic, the 2012 worked example, and the Dave Camp verification (Ways and Means chair for cycle 2012, a post he took in January 2011 with the 112th, ranking member only in the 111th).

It also records two smaller points:

- **`exec_roster_l1` follows by extension** -- a firm has no post-election counterpart, so there the suffix simply marks the pre-election vintage.
- **One caveat**: the source has one record per member-committee-Congress, so a mid-session change -- someone taking a chair partway through a Congress -- isn't captured.

That last one is the only remaining timing imprecision, and it's small. It would matter if a firm gave specifically because someone had just been elevated mid-Congress; that donation would show the person's start-of-Congress role instead.

--- AUTHOR [2026-07-29 19:33:12] ----------
1. I think we should make this point clear in classification_prompt_v2.md and v2 in taxonomy_decisions.md to make readers and LLMs less likly to get confused. 2. Following this clarification, do we need to redo the split of the incumbent_powerful category we just did? 3. The mid-Congress change is fine because I don't think it's common.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/Guidance" && grep -n "^## \|^### " ta

--- AGENT [2026-07-29 19:33:49] ----------
It's already inside the v2 section but sits after "What was rejected," which reads as an afterthought. Let me move it up to where it governs and retitle it:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/Guidance" && python - <<'PY' import i

--- AGENT [2026-07-29 19:34:06] ----------
Now making it unmissable at the point of use in the prompt:
[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/Guidance/classification_prompt_v2.md
[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/Guidance/classification_prompt_v2.md
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/Guidance" && python - <<'PY' import i
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && python -c " import pandas as pd d

--- AGENT [2026-07-29 19:35:13] ----------
All three settled.

1. The timing rule is now stated where it's used

In `taxonomy_decisions.md` -- moved up inside the v2 section so it sits with the category table rather than after the rejections, and retitled *"What `_l1` means, and why it is not a lag behind the donation."*

In `classification_prompt_v2.md` -- it appears three times now, deliberately:

- ?0, with the full explanation and the Dave Camp verification
- **At category 2**, because `cmte_l1` keys on it: *"despite the suffix, that is the Congress sitting while the donation was made... the roster a donor could actually see"*
- **At category 4**, with an instruction rather than a description: *"Do not adjust for the suffix, and do not go looking for a more current measure; there isn't one that a donor could have seen."*

That last phrasing matters for an LLM. A model that reads `_l1` as "lagged" might otherwise try to *compensate* -- reaching for the post-election Congress on the theory that the supplied field is stale. Telling it not to is more robust than explaining the convention once at the top.

```
Category 4 also now says explicitly that `cand_ever_power_l1` records past power and must **not** be used
there, since the two names are one character apart.

## 2. No redo needed

The split keys on `cand_power_l1`, and the clarification confirms that variable already means power held
during the donation window through election day -- which is the definition you specified. Nothing about the
data changed; only my understanding of the name did.

I verified the file rather than asserting it: all three categories still match their stated conditions
exactly, so **no observation needs reclassifying.**

## 3. Mid-Congress changes

Agreed and left as a recorded caveat. Worth one line of context for later: it would only bite if a firm gave
specifically *because* someone had just been elevated mid-session, and that donation would show the
start-of-Congress role instead. Rare, and it would understate `incumbent_powerful` rather than inflate it --
so the direction is conservative.

--- AUTHOR  [2026-07-29 19:46:51] ----------------------------------------
1. You can record the v2 classification results in a classification_20260729_claude-opus-5_overview.md as an
extension of v1 result. 2. Similarily, you can make 1-2 page in the slide deck that shows the v2 result as ab
extension of v1 result.

--- AGENT   [2026-07-29 21:14:52] ----------------------------------------
Both done.

## Memo -- section 8 of `classification_20260729_claude-opus-5_overview.md`

Written as an extension rather than a replacement, so sections 1-7 still describe v1 and the reader can see
what changed. It covers the split and the new priority order, the behavioural evidence, the two things tested
and rejected, how the file was produced, and the `_l1` convention that tripped us up -- including the Dave
Camp verification.

## Slide -- page 8, "Refining the Largest Residual"

It opens with the problem rather than the fix: *43% of donations sat in a category defined by what was
absent.* Then the three-way split against a committee reference row:

| | Donations | Median gift | Gave again 3+ cycles |
|---|---|---|---|
| *(committee, for reference)* | *524* | *$2,000* | *26%* |
| Incumbent, **powerful** | 54 | $2,000 | **35%** |
| Incumbent, **access** | 292 | $1,500 | 20% |
| **Contestant** | 85 | $1,000 | **1%** |

The two readings are stated as findings, not left for the audience to derive: donations to the powerful look
like committee donations and are *more* persistent; donations to contestants almost never repeat, so they can
be neither relationship maintenance nor access.

It closes with **what we did not split** -- chair versus member of the relevant committee, $2,250 against
$2,000 with identical repeat rates. That belongs on the slide because it shows the split was tested rather
than assumed, which is the thing a sceptical listener will want.

## Two notes

I **dropped the "same state as HQ" column** from the slide table. At 30/22/28 across the three groups it
doesn't separate them, so it was taking space without doing work. It's still in the memo where space is free.

One **4pt overfull vbox** remains on the new frame -- smaller than a descender, not clipping anything. I
```

verified the page renders complete, source note and all. I spent more passes on that than it deserved; flagging it rather than chasing it further.

--- AUTHOR [2026-07-29 21:17:56] ----------
1. I think many Incumbent candidate may not hold a rank in any committe? If so, would it be more accurate to not include "rank" in "Incumbent, access -- rank and file"? Or is my understanding is incorrect? 2. Do you think if we should do v3 taxonomy that has ideology? One concern I have is that it may be difficult to define ideology for both firms and candidates?

--- AGENT [2026-07-29 21:18:24] ----------
Both good questions. Let me check the first one against the data:
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && python -c " import pandas as pd d

--- AGENT [2026-07-29 21:18:46] ----------
96% of them **do** hold committee seats -- 2.2 on average. So the category is "no leadership post," not "no committee."

Your reading of "rank" as a committee rank is a misparse of the idiom (*rank and file* = ordinary members), but that's exactly the reason to change it: if a coauthor misreads it, an audience will.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/AI Talk/Slide" && python -c " import

--- AGENT [2026-07-29 21:19:06] ----------
The other occurrences are correct usage (chair *vs* rank-and-file member of a committee). But the prompt's `motive_detail` value should match:
[action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance/classification_prompt_v2.md
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python - <<'PY' import pandas as pd P='2026.07 AI - Political Donation M
[action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation Motive\AI Talk\Slide"; & "C:\Users
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && git add -A && git commit -q -F -

--- AGENT [2026-07-29 21:20:24] ----------
1. Relabelled -- you caught a real ambiguity

96% of `incumbent_access` candidates hold committee seats, 2.2 on average. Only 11 of 292 hold none. So the category means *no leadership post*, not *no committee* -- and "rank and file" invited exactly the misreading you had.

The slide and the prompt's `motive_detail` value now say **"no leadership post,"** and the prompt records the 96% so the boundary can't be misread. I left the other "rank-and-file" references alone -- those describe a chair *versus* an ordinary member of a committee, which is the idiom used correctly.

2. On ideology -- your concern is half right, and that half is the easy half

Candidate ideology is not the problem. DIME's dynamic CFscore and DW-NOMINATE are established published measures. The only care needed is vintage: use the **t-1 dynamic** score, never the static one (fitted over the whole 1979-2024 history, so look-ahead by construction) and never the contemporaneous one (partly determined by the very donation being classified).

Firm ideology is the problem -- so don't measure it. I'd argue we should never try to define a firm's ideology. What the category needs isn't an ideology construct; it's whether *this donation fits a pattern of one-sided giving*. That's directly observable from the donation master with no new data:

I built it to check feasibility. Firm partisan tilt at t-1 -- the share of the firm's PAC dollars going to Republicans in the prior cycle:

Coverage	**837 of 1,000 rows** (83.7%) have a prior-cycle giving record
Median prior-cycle Republican share	0.61

And the discriminator separates in the right direction:

	lopsided (>=80% to one party) **and** aligned with this donation

```
| `incumbent_access` | **18.6%** (45 rows) |
| `committee` | 12.7% |

So an ideology category would claim roughly 45 of the 292 `incumbent_access` rows -- about 4.5% of the sample
-- and it's *less* prevalent among committee-motivated donations, which is what you'd want if the two motives
are distinct.

**My recommendation: yes to v3, but built this way.** Define the category on the firm's *giving pattern*, not
on any firm-ideology score. Two conditions: the firm gave lopsidedly to one party last cycle, and this
donation goes to that party.

There's a sharper test available too, which the sample period supports. A *pragmatic* PAC shifts toward
whoever controls the House; an *ideological* one holds its tilt through turnover. Control changed in 2006,
2010 and 2018, so you can distinguish them behaviourally rather than by assertion -- and that would be a
genuinely novel measure rather than a borrowed score.

Two cautions. It takes the taxonomy to eight categories, which is past comfortable. And 16% of rows have no
prior-cycle giving history, so the category is unavailable for first-time donors -- those would have to stay
in `incumbent_access` with the reason recorded.

--- AUTHOR  [2026-07-29 21:33:19] ----------------------------------------
1. Let's not use "no leadership post", but "may sit in other committees" on page 8 because I think it's
clearer. Then we can also include the information like "96% of them do hold committee seats -- 2.2 on
average." on that page so the audiance knows the political strength of the incumbent_access. One addtional
question: on avergae, what's the percentage of House representatives that don't sit in any committee? You
don't need to look at my data, I just want to have a rough number. 2. What does "Gave again 3+ cycles" mean
on page 8? Does it mean giving again in the next cycle or giving again for the next three cycles? We should
make the point clear or drop it. I think it might be better if we have a column of the percentage of the
three category out of 43%, so the audiance will immediatelly knows link the contents on two pages, or we can
have one separate page that shows the whole breakdown with the updated taxonomy where the percentage of other
categories are the same to their numbers on page 6. 3. I think you can add 1-2 bullet points on firm partisan
tilt on page 3/7 as it can be one piece of background information, including % of firms whose >=80% goes to
Republic and Democratic Party respectively. To have more space on that page, we can make the table smaller.

--- AGENT   [2026-07-29 21:33:42] ----------------------------------------
Let me get the numbers for the partisan-tilt bullets first.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && python -
      ↪  <<'PY' import pandas as pd m=pd.read_stata('2024.12 Supply chai

--- AGENT   [2026-07-29 21:34:05] ----------------------------------------
Now the slide edits. First page 8:
      [action] Read: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk/Slide/trial_sample.tex

      [action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research
      ↪  projects\2026.07 AI - Political Donation Motive\AI Talk\Slide"; & "C:\Users

--- AGENT   [2026-07-29 21:36:03] ----------------------------------------
Down to a single **0.18pt** box -- a hairline. Verifying both pages render fully:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && PYTHONIOENCODING=utf-8 python -c
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && git add -A && git commit -q -F -
```

```
--- AGENT   [2026-07-29 21:36:45] ----------------------------------------
All three done. Deck is 8 pages, one 0.18pt hairline box.

## 1. Page 8 relabelled

`Incumbent, access -- may sit on committees`, plus a new bullet that states the point directly: *"'Access'
does not mean politically weak: **96%** of them sit on committees, **2.2** on average -- they simply chair
none."*

**On your side question:** roughly **1-2% of House members hold no standing committee assignment.** It's
essentially the Speaker, who by tradition takes none; sometimes the floor leaders and whips, who hold few or
none; and members seated mid-Congress in special elections still awaiting assignment. Everyone else has at
least one, because committee seats are how the House does business and members compete for them. Our
incumbents are at 98.8%, which matches.

## 2. "Gave again 3+ cycles" was ambiguous -- and neither of your readings

It wasn't "gave again next cycle" or "gave for three more cycles." It counts donations that are the **third
or later cycle of giving to that same candidate** -- a measure of relationship depth, looking backward.
Relabelled **"3rd+ cycle with this candidate."**

I also added your **"Share of that 43%"** column -- 12.5 / 67.7 / 19.7 -- so the audience connects the split
straight back to the residual named on the earlier slide without doing arithmetic. That was the better of
your two options: a separate full-breakdown page would repeat four numbers the audience already saw, and the
linkage is the only thing they actually need.

To make room, the "what we did not split" point moved into the source note. It's still there for anyone who
asks, but it was the least load-bearing item on the slide.

## 3. Partisan tilt added to page 4

| | share of firm-cycles |
|---|---|
| >=80% to Republicans | **20%** |
| >=80% to Democrats | **3%** |
| Split between 20-80% | **77%** |

Median Republican share 0.61, computed across 10,530 firm-cycles in the donation master. Table set in
`footnotesize` to fit.

The bullet closes with why it's there rather than leaving it as trivia: *one-sided giving is the exception,
which is what makes a firm's own tilt useful for identifying an ideological motive.* That plants the v3 idea
without committing to it -- and the 3% figure quietly warns that a Democratic-ideology category would be very
thin.

--- AUTHOR  [2026-07-29 21:55:41] ----------------------------------------
1. On page 8: change "they simply chair none" to a phrase meaning that "they chair none and sit on committees
that don't directly overview firm's primary industry". No need to make "1%" of "3rd+ cycle with this
candidate" for "Contestant --holds no seat" bold. 2. On page 4: make "Most corporate PACs give to both
parties, with a Republican tilt" the second bullet point and make "A firm's headquarters does not sit in one
congressional district" the first bullet point. Also I think "39% of the sample maps to 2-4 districts -- the
HQ ZIP straddles district lines" is bit of overclaim. I think one place correspond to one CD. The reason we
have "39% of the sample maps to 2-4 districts" because we only have and use firms' ZIP and the ZIP-CD
crosswalk map. I don't want to leave the impression with the audiance that "39% of firms in our sample maps
to 2-4 districts". We can use the word "may" or "coarsely". Also add ", with a median Republican share 0.61
tilt (computed across 10,530 firm-cycles)" after "Most corporate PACs give to both parties" (My idea is make
"Most corporate PACs give to both parties, with a Republican tilt" bit brief and add new information but
still keep it in one line). 3. The left footnote should be "Inferring Corporate Political Donations Motives
with LLMs".
      [action] Edit: G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/AI Talk/Slide/trial_sample.tex

      [action] PowerShell: Set-Location "G:\OneDrive - The Pennsylvania State University\PhD research
      ↪  projects\2026.07 AI - Political Donation Motive\AI Talk\Slide"; & "C:\Users

--- AGENT   [2026-07-29 21:58:02] ----------------------------------------
Down to 1.3pt. Verifying the three changes rendered:
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && PYTHONIOENCODING=utf-8 python -c
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && git add -A && git commit -q -F -

--- AGENT   [2026-07-29 21:58:44] ----------------------------------------
All three applied. 8 pages, one 1.3pt residual box.

## The overclaim -- you were right, and it mattered

*"39% of the sample maps to 2-4 districts"* did read as a fact about firms. It isn't: a firm sits at one
address in one district. The multiplicity is entirely an artefact of locating headquarters by **ZIP code**,
and a ZIP can straddle district lines.

The bullet now leads with the limitation rather than the number:

> **We locate a headquarters only coarsely, by ZIP code**
> A firm sits at one address in one district -- but a ZIP can span several, so for 39% of the sample the HQ
maps to 2-4 districts.

That ordering matters. The old version stated a striking number and then explained it away; this one tells
the audience what kind of number it is before they see it.

## Page 4 reordered and tightened

HQ coarseness first, partisan tilt second. The tilt headline now carries the number instead of the adjective
-- *"with a median Republican share of 0.61 across 10,530 firm-cycles"* -- and stays on one line.

To make room I dropped two low-information rows from the table (*gave in >1 quarter*, *median relationship
age*) and combined the party shares onto one line. The cycle-by-cycle ZIP detail moved to the source note.

## Page 8

*"They chair none of them, and none of those committees oversees the firm's primary industry"* -- that's the
actual content of the category, and it also pre-empts the obvious question about why a committee-holding
incumbent isn't in the committee category. Bold removed from the contestant 1%.

## Footer

Now **"Inferring Corporate Political Donations Motives with LLMs"** on every page.

One small thing, entirely your call: *"Donations Motives"* is slightly off grammatically -- *"Donation
Motives"* would be standard. I used your wording exactly rather than silently editing the title, but it's a
one-character fix if you want it.
```

```
--- AUTHOR  [2026-07-30 03:36:08] ----------------------------------------
The audiance of AI talk may not understand Claude code and expect me and Stefan to show what prompts and code
I used to generate this sample output. What should I show to them? I don't we can really show a log during
the presenation. I can show classification_prompt_v1.md, classification_prompt_v2.md, and
1.build_exec_roster_l1.py. I can also show my initial prompt to generate the sample (i.e., Prompt
Record.docx). Do I need to show something else, do you have a better idea?
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && echo "commits: $(git rev-list --c

--- AGENT   [2026-07-30 03:37:32] ----------------------------------------
Your list covers the **inputs** but not the **outputs or the process** -- and for an AI-methods audience
those are the more interesting halves.

## Show these four, in this order

**1. One filled output row.** This is the single most persuasive artifact you have, and it's not on your list:

| | |
|---|---|
| firm / candidate / cycle | Avis Budget -> James Maloney, 2000 |
| `motive` | `social_ties` |
| `motive_detail` | education: Harvard University, 4-year gap |
| `confidence` | 1 |
| `reasoning` | Maloney 1972 and director Len Coleman 1976 attended Harvard within five years.
Institutionally verified with both graduation years, but co-attendance is not proof of acquaintance. |
| `source_1` | Wikidata `educated_at` + BoardEx degree year \| URL \| date |

In ten seconds an audience sees that the output is structured, self-explaining, cites its source, **and
reports its own low confidence.** No prompt text achieves that.

**2. The four-file architecture, not the prompt text.** A full prompt is unreadable on a slide. What
transfers is the separation of concerns: `taxonomy_decisions.md` (what the categories are and why),
`classification_prompt_v*.md` (what the model receives), `run_procedure.md` (how a run is executed and
checked), `_runlog.md` (conditions of each run). That's a reusable pattern anyone in the room could adopt
tomorrow.

**3. `git log --oneline` -- this is your answer to "show us the log."** You have **43 commits** with
substantive messages. Nobody wants a transcript; they want evidence of process. And the log's most credible
feature is the reversals: *"Document the `_l1` time convention rather than renaming," "Correct row 721:
United Parks was identifiable," "Drop the roster cap."* A clean log looks curated. One with visible course
corrections looks real.

**4. Your initial prompt** -- yes, show it. It's short, it's the origin of everything else, and the AFA
requires submitting it anyway.

## The thing missing from your list, and I'd make it a full slide

**One case where the AI was confidently wrong, and the check that caught it.**

Every AI talk says the tool made work faster. Almost none shows where it produced plausible, well-formatted,
wrong output. That's the most valuable thing you can give this audience, and it costs you nothing in
credibility -- it *buys* credibility.

The best example is intuitive to anyone: matching candidate and executive schools gave **62
candidate-executive pairs**. Northwest Airlines had five Harvard directors and a Harvard congressman. Looked
like a finding. Adding one condition -- graduation years within five years -- cut it to **11**. Harvard has
hundreds of thousands of alumni; institution matching was mostly measuring institution size.

A second, more technical option if the room is quantitative: a regex matching `CEO` also matched **"Division
CEO"**, which put **540 people** in JPMorgan's 2014 executive roster against a real board of 17. Caught only
because the number was absurd on its face.

## What not to show

The full prompt on screen, and any raw transcript. Both are long, and neither rewards reading at presentation
speed. Hand the prompts out as files or put them in an appendix.

## Framing suggestion

Open the methods portion with *why these artifacts exist*: the AFA session requires submitting every AI
```

conversation, a human time log, and a human-versus-AI line count. That constraint is what forced the discipline -- and it explains to the audience why there's a paper trail at all, rather than making it look like unusual fastidiousness.

Want me to build these as three appendix slides -- the output row, the file architecture, and the error case? They'd sit after the current eight, so you can jump to them if asked rather than presenting them linearly.

--- AUTHOR [2026-07-30 03:43:44] ----------
Can you return my initial prompt to construct the 1000 observation sample for this exercise?

--- AUTHOR [2026-07-30 03:44:29] ----------
Can you return my initial prompt or the one similar to it to construct the 1000 observation sample for this exercise?

--- AGENT [2026-07-30 03:44:42] ----------
I should be straight about something first: **I've never seen your initial prompt.** The 2026-07-22 do-file predates any session I have a record of -- that's the gap recorded in `PROVENANCE.md`. Let me check whether `Prompt Record.docx` has it:

    [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && python -c " import zipfile,re try

--- AGENT [2026-07-30 03:45:23] ----------
`Prompt Record.docx` is locked by Word, so I can't check it -- close the file and I'll look. If the original is in there, use that rather than anything I write.

Failing that, here's a **reconstruction** derived by working backwards from the archived 2026-07-22 do-file. It asks for exactly what that script does:

> I need a 1,000-observation trial sample of corporate PAC donations to House candidates, drawn from my cycle-level donation master.
>
> **Source:** `2024.12 Supply chain - politics\Data\20250829\gvkey_cand_don_cycle_data_cycle_2000_22.dta` -- firm-candidate-cycle donation records, 2000-2022, keyed on gvkey, cand_id, cycle.
>
> **Sampling.** Keep House candidates only (`cand_office == "H"`). Cap each firm at 100 observations so no single firm dominates, drawing randomly within firm. Then draw 1,000 observations, of which exactly **500 must have `cand_office_st == "PA"`** and 500 must not. Set a seed so it reproduces.
>
> **Then merge on, in this order:**
>
> 1. **Candidate details** from the DIME crosswalk at `1.Common Dataset\Politics\2.Complied Data by Others\Database on Ideology, Money in Politics, and Elections\federal_candid_icpsr_crosswalk_1979_2022.dta`, restricted to House seats, matched on cand_id and cycle. Keep the candidate name and district; drop the ICPSR and Bonica identifiers I don't need.
> 2. **House committee assignments** from `1.Common Dataset\Politics\Committee Assignment\house_standing_cmte_cand_candid_1993_2022.dta`, matched on cand_id and cycle. Keep observations even where no committee record exists, but flag which ones have it.
> 3. **Firm headquarters** from `hq_firm_cd_cycle_2000_2024.dta` in the same 20250829 folder -- HQ state, congressional district code and district number, matched on gvkey and cycle.
> 4. **Historical GICS and company name** from `ccm_annual_gics_2000_2024_incorporate_historical_gics.dta`, matched on gvkey and year, using the historical rather than current classification.
>
> Drop any observation with no HQ state. Report distinct counts of cycle, gvkey and cand_id at the end so I can check the spread. Order the columns so firm identity comes first, then candidate, then the donation variables. Save as both `.dta` and `.csv` to `2026.07 Motives for Pol Donation\AI Talk\`, named `random_1000_house_firm_candidate_don_cycle_level_max100_per_firm`.
>
> Use `joinby` with `unmatched(both)` and show me the `_merge` tabulation at each step so I can see what matched.

One caution about using this for the AFA submission

This is not your initial prompt -- it's my inference of what it must have said. For the talk that's fine, as long as you say so. For the AFA appendix it isn't, because the requirement is the actual conversation.

Three honest options, in order of preference:

1. **Recover the original** from `Prompt Record.docx`. Best outcome -- close Word and I'll read it.
2. **Declare the sample construction as pre-existing human-authored infrastructure** and begin the documented AI record from the first session that has a transcript. This is what `PROVENANCE.md` already says, and it

```
costs you nothing: the call for papers permits direct human contributions provided they're documented.
3. Submit the reconstruction **explicitly labelled as reconstructed**, with a note that the original session
wasn't captured.

Option 2 is cleanest and it's already written down. A reconstruction presented as the original would be the
one thing in this project's record that isn't true.

================================================================================================================
SESSION 2 of 11   e46c5e60-d793-4cdb-85d3-279ef78aa193

# Session catch-up (reconciliation) routine

Memos are written by Claude sessions; the user works between sessions
(reviewing, rerunning in Stata, editing scripts, changing decisions).
NEVER treat the memo's NEXT line or recorded results as current state
without reconciling first.

## 1. Establish the memo baseline
Read the project status memo's latest entries and its NEXT line; note the
date of the last recorded entry.

## 2. Detect offline work
Scan for files modified AFTER the last memo entry date (code folders,
output tables, drafts, the memo itself):
- Git Bash: `find <code/output/writeup dirs> -newermt "YYYY-MM-DD" -type f`
  (or compare mtimes with `ls -lt | head`).
- If the code folder is a git repo: `git status` + `git diff` against the
  last session's commit gives EXACT deltas -- prefer this when available.

## 3. Reconstruct, then confirm (do NOT ask the user to enumerate)
The user makes many changes between sessions -- major and minor mixed --
and should not have to list them. READ the changed files and reconstruct
the changelog yourself:
- Changed scripts: read them and compare specifications, variable
  definitions, and windows against what the memo describes.
- Regenerated outputs: compare key coefficients in current result files
  against the numbers recorded in the memo.
- Drafts: skim changed sections (python-docx for .docx).
Classify each change MAJOR (decision, specification, sample, or results
changed) or MINOR (refactoring, formatting, table cosmetics). Present the
reconstructed changelog in that order and ask the user only two things:
(a) is this reading correct, and (b) the WHY behind major changes that
cannot be inferred from the files. Without version control the diff is
against the memo's description, not the true prior file -- flag
reconstructions that are uncertain rather than guessing.

## 4. Record the reconciliation
Append a short memo entry: "User offline work since <date>: <changes>;
NEXT revised to: <...>" -- so the offline work enters the inter-session
record. Tombstone depth unless the user's changes are substantive.

## 5. Protect user modifications
Before editing ANY file this session, re-read its current content -- never
edit from memory of a previous session's version. If a script differs
from what the memo describes, the user's version wins; flag the
discrepancy instead of "fixing" it back.

## 6. Then proceed
Only after 1-5, act on the (possibly revised) NEXT line or the user's
stated task.
```

```

--- AGENT   [2026-08-11 00:22:06] ----------------------------------------
I've reconciled the repo against the memos. Here's what I found.

## Memo baseline

No status memo exists yet (CLAUDE.md says "to be created at the first wrap-up"). The de facto record is three
files, all last written **2026-07-29**: `Guidance/_runlog.md` (runs 1-3), `Guidance/taxonomy_decisions.md`
(v1/v2), and `AI Talk/classification_20260729_claude-opus-5_overview.md`. Last commit `9548fa1`, 2026-07-29
17:58. Today is 2026-08-10, so there are **12 days** to reconcile.

## Reconstructed changelog since 2026-07-29 17:58

**1. Deck hand-edited by you and recompiled -- uncommitted** (`trial_sample.tex` 18:07, `.pdf` 18:06, both
after the last commit; no agent transcript covers them). Three changes, and the PDF does reflect all of them:

| Page | Change | Read |
|---|---|---|
| 4 headline | "Most corporate **PACs** give to both parties" -> "Most **firms** give..."; 10,530 firm-cycles
moved into parentheses | MINOR -- tightening |
| 4 sub-bullet | Dropped the tail: *"-- which is what makes a firm's own tilt useful for identifying an
ideological motive"* | **MAJOR** -- retracts a forward claim about the deferred party/ideology category |
| 8 frame title | "Refining the Largest Residual" -> "Refining the *Incumbent/contestant* Residual" | MINOR
-- names the thing |

**2. A short agent session on 2026-07-30** (24 messages, ~9 minutes, in the same `be55af56` transcript) that
**changed no files**. You asked what to show an AI-methods audience who won't know Claude Code. The
recommendation was: one filled output row, the four-file architecture rather than prompt text, `git log
--oneline` (43 commits, reversals visible), your initial prompt, plus a new slide on **one case where the AI
was confidently wrong** -- the Harvard institution match (62 pairs -> 11 once graduation years were required)
or the `CEO` regex that matched "Division CEO" and put 540 people in JPMorgan's 2014 roster. Three appendix
```

slides were offered and never built.

3. `Prompt Record.docx` edited 2026-07-31 20:15. Untracked by design (`.gitignore:45`), so no diff is possible -- this reconstruction is from current content only. It holds your scoping prompt, the five coauthor categories, the ChatGPT outcome-category list, and the coauthor's reply narrowing to measurable categories. **It does not contain the 2026-07-22 sample-construction prompt** -- which is what the Jul 30 session hoped it would. The `PROVENANCE.md` gap therefore stands unchanged, and Option 2 (declare sample construction as pre-existing human-authored infrastructure) is still the position.

4. Nothing else moved. No data, code, taxonomy, or classification output changed since Jul 29.

Two things the record is now behind on, flagged not fixed

- **`sessions/` was never refreshed.** The archived copy is the Jul 27 snapshot (608 KB); the live transcript is **6.4 MB** covering Jul 27-30. `scripts/archive_sessions.py` hasn't been re-run. `PROVENANCE.md`'s session log likewise stops at Jul 27 and records none of the Jul 28-30 work. This is the AFA appendix (1) requirement.
- **`HUMAN_LOG.md` has two entries, both with `?` minutes**, and nothing for Jul 28-31 -- including your deck edits and the docx work. That's appendix (2).

AFA submission is **2026-08-31 -- 21 days out**.

Done. Both commits are in, and the split verified: the deck's three hand-edited lines now register as human
(`AI=345 HUMAN=3`), which is exactly what the naive method got wrong.

## Reconciliation

Your offline work is reconstructed and recorded in `PROVENANCE.md` and the new `STATUS_MEMO.md`: the 07-29
deck edits, the 07-30 discussion session, the 07-31 docx edit, and the talk. The deck edits are committed as
yours, with no `Co-Authored-By` trailer.

## AFA record -- two corrections you should know about

Both verified against the data, not inferred:

- **The 2026-07-22 do-file as you wrote it is not in the repo.** The `_archive/` copy already carries six
```

agent edits from 06:00-06:01Z on 07-27 -- its own header says the PA quota was removed that day. At most 33 of its 174 lines are the agent's, so >=141 are yours.
- **The archived CSV/DTA are not the PA-stratified draw either.** Both are byte-identical, 1,792 rows / 690 triples, **4.7% PA** -- the post-removal rerun. `CLAUDE.md` claimed `_archive/` held the PA-stratified version; corrected. The 2026-07-22 sample is genuinely gone.

Appendix (3): 144 human lines against 3,022 AI -- 4.5%. `scripts/line_fractions.py` recomputes it. Naive blame reports 100% AI, because the `bc3076c` snapshot commit carries an AI trailer over your do-file; the script corrects that one case and names the evidence. Report it beside the **81 human turns** -- 4.5% alone misdescribes a project where every substantive call is yours.

One number was mislabeled

The v2 justification table's **"repeat rate"** (35 / 20 / 1 / 26) is `nth_cycle > 2` -- the rate of reaching a **third** cycle with the same candidate, not of giving twice. It reproduces exactly, as do the medians and state-match columns. The ranking survives all three definitions (second-donation: 57/40/5/51; prior-cycle: 48/36/2/44), so the conclusion holds. **The deck always had it right** -- "3rd+ cycle with this candidate" -- so nothing wrong was presented. Both memo files relabeled.

v3 -- closed as no

The v2 file said to decide on whether `incumbent_access` stays "large and undifferentiated." It stays large, and the diagnosis is sharper than undifferentiated:

- **283 of 292 rows at confidence exactly 3**, nine at 2. No internal gradation whatsoever.
- **`motive_2nd` is `others` for 209 of 292 (72%).** Asked for a runner-up, the model had nothing.
- **96.2% hold a committee seat**, 2.16 on average, none judged relevant.

So the category is the negative image of the committee-jurisdiction call, not a motive wanting subdivision. Candidate party separates nothing inside it -- median $1,500 vs $1,000 (**p = 0.58**), third-cycle rate 20.7% vs 17.9% (**p = 0.65**) -- failing the standard v2 itself met.

Recorded in `taxonomy_decisions.md` under the original deferral, so it reads resolved. Two things I kept explicitly open there: candidate party is **not** firm alignment, so reopening requires firm partisan concentration at t-1, never party; and the in-state-not-in-district split (n=64) has one significant gap (**p = 0.032** on persistence, size n.s. at p = 0.105), shows the same gradient among committee rows, and would reopen your district-only ruling -- recorded, not recommended.

Open

Why did you cut the p.4 clause -- "which is what makes a firm's own tilt useful for identifying an ideological motive"? It's the one input to the v3 decision that isn't on the record, and it removed the exact claim v3 would have rested on. If you cut it because you'd stopped believing firm tilt can identify ideology, that's a stronger reason for today's "no" than anything I measured, and it belongs in the taxonomy file.

`STATUS_MEMO.md` NEXT also carries: the taxonomy of record is still *derived* rather than run (`classification_prompt_v2.md` has never been executed), and correctness has never been tested -- the 200-row human coding sheet has sat uncoded since 07-28.

--- AUTHOR [2026-08-11 01:30:35] --
I'm happy with the new classification taxanomy. One shortcoming is when we consider Geography motive for political donations, we currently only consider HQ locations. But firms may donate to candidates who represent the district where its important establishments are located, so we should classify those donations as geography category as well. G:\OneDrive - The Pennsylvania State University\PhD research projects\1.Common Dataset\Infogroup includes data of infogroup_business and \Infogroup\establishment_footprints\code has the code to merge the data to Compustat. My idea is since I may also use establishment location data of public firms for other projects, can we fist update infogroup_public_establishments_2014_2019.parquet to the period between 1997 and 2025? Then we can in other future analysis, we will consider establishment locations for donations driven by geography motive as well.

--- AGENT [2026-08-11 01:30:42] --
Good -- this is open item O4 in the taxonomy file, and building it as a shared asset first is the right order. Let me look at what's there before proposing anything.

--- AGENT   [2026-08-11 01:35:11] ----------------------------------------
Scan is ~40% through (about 15 minutes left). Two blockers are already confirmed, and they matter for scoping.

## What the pipeline actually is

Two steps, and your ask sits on the first:

| | Output | What it is |
|---|---|---|
| 1.1 | `infogroup_public_establishments_2014_2019.parquet` (309 MB) | Establishments of ticker-bearing
parents, with lat/long |
| 1.2 | `eld_firm_establishments_2014_2019.parquet` (207 MB) | The same panel **keyed on gvkey** |

For the geography motive you need 1.2 -- a donation row is `gvkey x cycle`, so establishments have to carry a
gvkey. Extending 1.1 alone leaves the asset unusable for this project, so I'd scope both.

## Two hard blockers, verified against the extracts

- **CRSP stocknames ends 2024-12-31.** Active name rows: 9,182 in 1997, 6,944 tickers in 2014, **0 in 2025**.
The ticker->PERMCO step fails outright for archive year 2025.
- **CCM annual starts at fyear 1999**, and 1999 is partial (1,614 rows against ~11-12k in normal years).
**1997 and 1998 have no coverage at all.**
```

So 1997-1998 and 2025 -- three of the 29 years you want, including both endpoints -- cannot be gvkey-matched with what's on disk. Both fixes are small WRDS pulls (a full-history `crsp_stocknames` refresh and `ccm_annual` back to 1997), but they need your Duo approval and, by your convention, go through the `crsp-wrds-expert` agent.

Three things I'd change in the build, not just the date range

- **The current script holds every year in memory and concatenates at the end.** Fine for 6 years; 29 years is roughly 5x the rows and will not hold. I'd stream year-by-year into a `ParquetWriter`.
- **Write to a new file, not over the old one.** The README warns that two BWE notebooks (ELD and Port) read the 2014-2019 files by name. New `_1997_2025` outputs leave them working.
- **The parent linkage may be incomplete.** The build links establishments to parents through `parent_number` alone, but the file also carries `subsidiary_number` and `company_holding_status`, which it ignores -- while the README describes the output as "ticker-bearing + subsidiaries." Worth a look before a 29-year run rather than after.

One thing this buys you that I didn't expect

Latitude and longitude are populated on essentially every record. That means an establishment can be assigned to exactly one congressional district from its coordinates -- where your HQ measure inherits the ZIP-straddling problem and maps 39% of firm-cycles to 2-4 districts. The establishment-based geography motive could be *cleaner* than the HQ one, not just broader. It's a design fork for later (coordinates + district shapefiles vs. your existing ZIP-CD crosswalk, which would keep the two measures consistent), and I'm not deciding it now.

I'll report the per-year coverage table when the scan finishes -- that determines which archive years exist at all and how many ticker-bearing parents each has.

--- AUTHOR [2026-08-11 01:45:25] ----------
1. I think we can build a new gvkey-establishment location data for the period between 1997 and 2024. You can pull the needed data from WRDS. The generated sample will be saved in \1.Common Dataset\Infogroup. You can also stream year-by-year into a ParquetWriter and create an updated python code for this task. 2. Does infogroup data also include the latitude and longitude of the HQs? If so, we can later use it for the HQs' district location as well, considering district boundary changes over time. Also, we will eventually only use even year establishment year for Geography motive to remove the bias caused by relocation during a cycle. These two issues are project specific after we construct the gvkey-establishment sample for the period between 1997 and 2024.

--- AUTHOR [2026-08-11 01:46:19] ----------
Base directory for this skill: C:\Users\DevinZ\.claude\skills\wrds-schema

WRDS Schema Pre-loader

You are starting a session that involves WRDS PostgreSQL queries. Before writing any queries, load the schema knowledge you need by dispatching specialist agents in parallel.

Connection

Connection details are in `~/.pg_service.conf`; password in `~/.pgpass`.

```bash
psql service=wrds
```

For Python, use `psycopg2.connect("service=wrds")`. Do NOT use `pd.read_sql` (broken with psycopg2 on Python 3.13) -- use cursors directly and cast `Decimal` to `float`.

Prerequisite: The specialist agents (`crsp-wrds-expert`, `optionmetrics-wrds-expert`, `taq-wrds-expert`) must have `Bash` in their `tools:` frontmatter in `~/.claude/agents/`. Without it, they cannot run `psql` queries.

What to do

```
Based on `CRSP stocknames and CCM link history for ticker-to-gvkey matching 1997-2024` (or "all" if none
given), launch the appropriate specialist agents **in parallel** using the Task tool. Each agent should query
the WRDS database to retrieve current schema details and return a concise reference.

### Agent dispatches

For each requested database, launch a Task with `subagent_type` set to the matching specialist:

| Keyword | Agent | Task |
|---------|-------|------|
| `crsp` | `crsp-wrds-expert` | Retrieve schema for `crsp.dsf`, `crsp.dsi`, `crsp.msf`, `crsp.msi`,
`crsp.stocknames`, delisting tables. Confirm column names (`date` not `caldt`), PERMNO lookup for SPY
(84398), index columns in `dsi` (`spindx`, `sprtrn`). Note Decimal type from psycopg2. |
| `optionm` | `optionmetrics-wrds-expert` | Retrieve schema for `optionm.opprcd{YYYY}` (yearly partitioned),
`optionm.securd`, `optionm.zerocd`. Confirm: `strike_price` is strike*1000, SPX SECID=108105, SPY
SECID=109820, XSP SECID=189691. Column names for options tables. LEAPS expiry cycles (Jun/Dec for 2Y). |
| `comp` | `crsp-wrds-expert` | Retrieve Compustat `comp.funda` key columns, CCM linking via
`crsp.ccmxpf_lnkhist` (PERMNO-GVKEY, linktype LC/LU, linkprim P/C). |
| `taq` | `taq-wrds-expert` | Retrieve TAQ table structure, trade filtering rules (TR_CORR, TR_SCOND), NBBO
tables. Note: TAQ requires SAS on WRDS, not SQL. |

### Agent prompt template

Each agent should receive a prompt like:

> You are pre-loading schema knowledge for a WRDS session. Query the database to confirm current table
structures and return a concise reference card. Do NOT write analysis code -- just retrieve and summarize
schema.
>
> Run these queries via psql:
> 1. `SELECT column_name, data_type FROM information_schema.columns WHERE table_schema='...' AND
table_name='...' ORDER BY ordinal_position;`
> 2. Any quick validation queries (e.g. `SELECT MIN(date), MAX(date) FROM crsp.dsi LIMIT 1`)
>
> Return a compact reference with: table name, key columns (name + type), date ranges, important IDs, and
known gotchas.

### After agents return

Compile their results into a single **Schema Reference** block and present it to the user. Keep it compact --
a lookup table, not prose. Example format:

```
=== CRSP ===
crsp.dsi: date(date), vwretd(numeric), sprtrn(numeric), spindx(numeric) | 1926-2024
crsp.dsf: permno(int), date(date), prc(numeric), ret(numeric), vol(numeric) | 1926-2024
  SPY PERMNO: 84398
  Gotcha: psycopg2 returns Decimal, cast with .apply(float)

=== OPTIONMETRICS ===
optionm.opprcd{YYYY}: secid, date, exdate, cp_flag, strike_price(/1000!), best_bid, best_offer,
impl_volatility, delta, volume, open_interest
  SPX SECID: 108105 | SPY SECID: 109820 | XSP SECID: 189691
  2Y LEAPS: expire Jun/Dec only, DTE 600-830 range for quarterly initiation
optionm.zerocd: date, days, rate | zero-coupon rates by maturity
optionm.securd: secid, ticker, cusip, index_flag
  Gotcha: strike_price is strike * 1000 (divide by 1000 in queries)
```

Known gotchas (always include these)

1. **`pd.read_sql` broken on Python 3.13** -- use `cursor.execute()` + `cursor.fetchall()` +
`pd.DataFrame(rows, columns=[...])`
2. **Decimal type** -- psycopg2 returns `decimal.Decimal` for numeric columns. Always `.apply(float)` or
`float()` before math/numpy operations.
3. **CRSP column names** -- `crsp.dsi` uses `date` (not `caldt`), `spindx` (not `sprindx`)
4. **OptionMetrics strike** -- `strike_price` column stores strike * 1000. Divide by 1000.
5. **OptionMetrics yearly tables** -- option prices are in `optionm.opprcd{YYYY}`, NOT a single table. Loop
years 1996-2025.
6. **SPX LEAPS cycle** -- 2-year options only expire in June and December. Monthly initiations produce
```

```
duplicate expiry targets. Use quarterly initiation for 2Y.
7. **Exec pricing** -- use `(best_bid + 3*best_offer) / 4` for realistic execution (between mid and ask).

HQ coordinates: **99.99% populated, every year back to 1997.** Answer to your Q2 is yes.
      [action] Bash: cd "C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-Univer⌋
      ↪  sity-PhD-research-projects-2026-07-AI---Political-Donation-Mo

--- AGENT   [2026-08-11 01:58:09] ----------------------------------------
Pass 2 is running (~15 min). Here's where things stand.

## Your Q2: yes, and it's better than I expected

The parent/HQ record is itself an establishment row, so it carries coordinates like any other:

| | HQ (ticker-bearing) records, 1997-2024 |
|---|---|
| Records | 142,182 |
| **Latitude / longitude** | **99.99%** |
| ZIP / state | 100% |

Coverage is 100.00% in 1997 and never drops below 99.93% in any year. So you can assign HQ districts by
point-in-polygon against the district map in force for each cycle, instead of through the ZIP crosswalk that
currently maps 39% of firm-cycles to 2-4 districts. Boundary changes handle themselves, since you'd match
coordinates against the cycle's own boundaries.

**The weak link, and it's on the firm side, not the geography side.** Infogroup only tags a subset of listed
firms with a ticker: **2,813 distinct tickers in 1997 against 9,031 CRSP-active tickers (31%)**, rising to
5,757 against 9,460 in 2024 (61%). An establishment-based geography measure will be thin in the early cycles.
Worth measuring against your donation sample's gvkeys specifically rather than against all of CRSP -- that's
the denominator that matters, and I'll do it once the panel exists.

## What's built

**WRDS pulls** (done, in `Infogroup\establishment_footprints\identifiers\`) -- the asset no longer depends on
the Bullwhip project's extracts:

- `crsp_stocknames_20260810.csv` -- 78,325 rows, 9,031 tickers active in 1997, 9,460 in 2024
- `ccm_lnkhist_20260810.csv` -- the CCM link *history*, not an annual panel. This is what fixes 1997-1998:
the old build joined a `fyear`-keyed panel starting in 1999, so the two earliest years had no coverage at all
- `compustat_names_20260810.csv` -- fallback, now bounded by `year1`/`year2`

**`code\1.extract_public_establishments.py`** -- two streaming passes, writing per batch. Pass 1 took 16
seconds and found 142,182 ticker records; pass 2 is scanning now.

## The thing that would have quietly poisoned the data

In archive years 1998-2002, Infogroup writes `parent_number = '000000000'` as a "no parent" sentinel rather
than leaving it null -- 78% of rows in a 200k sample of 2000, against 11-15% genuinely parented rows in the
years either side.

**1,993 ticker-bearing records carry that sentinel.** Matching on `parent_number` unfiltered, as the
2014-2019 script does, would have attached roughly 8.6 million unrelated establishments per year to those
firms and reported it as their footprint. It never bit before because the old build started in 2014. The
guard is `NULL_PARENTS` in step 1, with a comment saying not to remove it.

Two further corrections are in `code\2.match_establishments_to_gvkey.py`:

- **The old build dropped the headquarters.** It inner-joined establishments onto the parent map on `(year,
parent_number)`, so any ticker record without a parent_number -- 6,759 of them, plus the 1,993 sentinel cases
-- fell out entirely, taking the firm's HQ row with it. Those now match on their own `(year, abi)`. Given
what you want this for, losing HQs would have been the worst possible failure.
- **The Compustat ticker fallback is now time-bounded**, so a ticker reassigned to a different firm can't
leak across decades.

I'll run step 2 when pass 2 lands, then report per-year gvkey coverage and the overlap with your 599
donation-sample firms. Your even-year restriction and the district assignment stay project-side, as you said
```

```
-- I'm not building them into the shared asset.

--- AUTHOR  [2026-08-11 02:01:27] ----------------------------------------
We can also use Ticker to link Infogroup data and Compustat data, and then we add gvkey to Ticker. I only
want gvkey to be the firm identifier in the final sample.

Built and committed.

## The panel

`1.Common Dataset\Infogroup\establishment_footprints\infogroup_gvkey_establishments_1997_2024.parquet` --
**19,630,381 gvkey-establishment-years**, 7,767 gvkeys, 660 MB. GVKEY is the only firm identifier, as you
asked; `abi` stays because it identifies the establishment rather than the firm, and the ticker/parent_number
that built each link went to `gvkey_ticker_crosswalk_1997_2024.parquet` so the match is still auditable
without a second firm ID in the analysis file.

Every row has coordinates, plus ZIP/county/FIPS/tract/CBSA, SIC/NAICS and location employment. Firms per year
run 2,062 (1997) to 4,387 (2024); median firm-year footprint is 10 establishments.

## Your ticker->Compustat point

Both routes now run for every year and are compared before either is used. Where both fire they **agree
96.5%** (109,147 of 113,106 ticker-years). CRSP/CCM wins the other 3.5%, because its tickers are historical
and its links are dated while Compustat's ticker is the current one -- the direct route adds firms CRSP can't
resolve rather than overriding it. The Compustat side is bounded by `year1`/`year2` and to tickers
identifying exactly one gvkey in that window, so a reused ticker can't pull in a firm from another decade.
69.3% of Infogroup's 142,182 ticker records resolve to a gvkey.

## Your Q2: yes

HQ records carry coordinates on **99.99%** of ticker records -- 100.00% in 1997, never below 99.93% in any
year -- and `is_hq` flags them (98,084 of 98,320 gvkey-years have exactly one). So HQ districts can be
assigned point-in-polygon against the map in force for each cycle, which handles boundary changes by
construction and replaces the ZIP crosswalk that currently maps 39% of firm-cycles to 2-4 districts.

## What the raw file was hiding

Checking before building caught two defects in the inherited code that produce *wrong* data, not missing data:

- **`parent_number` carries a `'000000000'` sentinel in 1998-2002** -- 78% of rows in a 200k sample of 2000,
against 11-15% genuinely parented rows either side. **1,993 ticker-bearing records carry it.** Matching
unfiltered, as the legacy script does, attaches ~8.6M unrelated establishments per year to those firms. It
never bit because that build started in 2014.
- **The legacy inner join drops the headquarters** -- 6,759 ticker records have no parent_number, plus the
1,993 sentinel cases, and all of them fell out of the output entirely. For a design about where a firm *is*,
that's the worst thing to lose.

Links now come from `crsp.ccmxpf_lnkhist` rather than an annual panel starting at fyear 1999, which is what
makes 1997-1998 possible at all. 2025 is excluded deliberately: CRSP stocknames ends 2024-12-31, so nothing
in 2025 can carry a gvkey.

## Two things to settle before this becomes a motive

Both are project-side, both recorded in `STATUS_MEMO.md` and against O4, neither baked into the shared asset:

**Coverage trends with the calendar.** 470 of your 599 firms appear and 742 of 1,000 donation rows match an
```

establishment in the cycle year -- but 36.7% in cycle 2000 against 96.2% in 2022. Your sample already has the committee share trending the same direction (37.8% -> 70.9%). Treating "no establishment match" as "no establishment" would manufacture that trend rather than measure it, so the missing-data rule needs deciding first -- possibly restricting the establishment geography test to 2012 onward.

An "establishment" includes unstaffed locations. The largest footprints in the panel are Redbox kiosks (69,696 in 2017), UPS drop boxes and Dunkin' counters. A Redbox in a district is not a reason to give a congressman money, so this needs an `employee_size_location` or `address_type_indicator` filter before it touches a motive.

Your even-year restriction is noted in the memo as the rule for the measure, not the asset -- the panel keeps every archive year so other projects can use it.

--- AUTHOR [2026-08-11 02:25:21] ----------
I want to first be certain about the firm_establishment location sample before thinking about what we will use for the project. Two questions: 1. In infogroup_gvkey_establishments_1997_2024.parquet, we don't need to make gveky the only identifier. We can also include ticker in the sample as well. 2. Why the sizes of infogroup_gvkey_establishments_1997_2024 and infogroup_public_establishments_1997_2024 different so much? So gvkey doesn't cover all public firms?

--- AGENT [2026-08-11 02:25:40] ----------
Two good questions. The second one has a real answer that I should check rather than assert -- let me decompose the loss.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common

--- AGENT [2026-08-11 02:25:57] ----------
Size gap is mostly columns, not rows. Now decomposing the 7.33% row loss and diagnosing the unresolved tickers.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
↪ Dataset/Infogroup/establishment_footprints" && PYTHONIOENCODING=utf

--- AGENT [2026-08-11 02:27:19] ----------
7.32% from unresolved tickers, 0.01% from coordinates. Now -- why do those tickers fail?
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
↪ Dataset/Infogroup/establishment_footprints" && PYTHONIOENCODING=utf

--- AGENT [2026-08-11 02:27:53] ----------
Two things in that list are genuine defects, not out-of-universe firms. Checking Berkshire and Brown-Forman directly.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
↪ Dataset/Infogroup/establishment_footprints/identifiers" && PYTHONIO

--- AGENT [2026-08-11 02:28:22] ----------
That's the answer, and it exposes a real defect. Three sources write share classes three different ways:

Firm	Infogroup	CRSP	Compustat
Berkshire Hathaway	`BRK.A`	`BRK`	`BRK.B`
Brown-Forman	`BFA`	`BF`	`BF.B`
Crawford & Co	`CRDA`	`CRD`	`CRD.A`

None match exactly, so dual-class firms drop out. Let me measure how much a class-aware match recovers, with a name check to stop it inventing links.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
↪ Dataset/Infogroup/establishment_footprints" && PYTHONIOENCODING=utf

--- AGENT [2026-08-11 02:29:10] ----------
The guard is earning its place: without it 1,696 "recoveries", of which ~93% are junk (Mendocino Brewing -> MuniEnhanced Fund, BAB Systems -> British Airways). Stripping a letter off a 4-letter OTC ticker usually lands on an unrelated NYSE one.

At 0.9 similarity, 116 survive and the one bad case at 0.8 (CTI Industries -> Chart Industries) is excluded. Let me check what that's worth in establishments before wiring it in.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
↪ Dataset/Infogroup/establishment_footprints" && PYTHONIOENCODING=utf

--- AGENT [2026-08-11 02:30:41] ----------
13 firms, all clean -- but **265,049 establishment-years (+1.35%)**, because Berkshire Hathaway alone is

```
enormous. Worth having. Wiring it in along with your ticker column.

--- AGENT   [2026-08-11 02:34:37] ----------------------------------------
Checked it properly rather than guessing. Short answer: **the ticker match is already exact everywhere except
one narrow fallback, and that fallback is 13 firms you can audit in full.**

## Exact matching is clean where it runs

Routes A and B are both exact. And exact matching against CRSP doesn't hide ambiguity: across 211,421
ticker-years, a ticker maps to more than one PERMCO in just **17 cases (0.01%)** -- and **zero** after
preferring common shares. So there's no silent collision problem lurking inside the exact match.

## The only non-exact part, in full

Route C exists because the three sources spell share classes differently (`BRK.A` / `BRK` / `BRK.B`), so
dual-class firms match nothing. It contributes **13 firms, 265,008 establishment-years, 1.33% of the panel**
-- the entire list:

| ticker | gvkey | name | years | estab-years |
|---|---|---|---|---|
| BRK.A | 002176 | Berkshire Hathaway | 1997-2024 | 255,134 |
| CRDA | 003581 | Crawford & Co | 1997-2024 | 7,361 |
| NWSA | 012886 | News Corp | 1997-2008 | 1,251 |
| MOGA | 007549 | Moog Inc | 1997-2021 | 705 |
| LMCA | 032280 | Liberty Media | 2002-2005 | 339 |
| FCE.A | 004842 | Forest City Realty | 2018 | 109 |
| AHNA | 010439 | ATC Healthcare | 2007 | 44 |
| NRCIB | 065587 | National Research | 1998-2012 | 24 |
| BWL.A | 002342 | Bowl America | 2021 | 18 |
| BELFA | 002124 | Bel Fuse | 1997-1998 | 10 |
| FWVB | 031593 | First West Virginia Bancorp | 1997 | 8 |
| AGM.A | 015153 | Federal Agricultural Mtg | 2024 | 3 |
| SQZB | 037282 | SQZ Biotechnologies | 2023 | 2 |

Every one matched its CRSP/Compustat name at >=0.90 similarity. **Berkshire is 96% of the contribution** --
```

```
drop route C and you lose Berkshire Hathaway from all 28 years.

Your instinct is right about the danger, though: run the same rule *without* the name check and it proposes
1,696 matches of which ~93% are wrong (Mendocino Brewing -> MuniEnhanced Fund, BAB Systems -> British
Airways). The name check is doing all the work.

## Two wrong-match risks that exact matching does *not* fix

Worth knowing these are larger than route C:

- **3,959 ticker-years (3.5%) where CRSP and Compustat give different gvkeys for the same exact ticker.** I
keep CRSP. Exact matching doesn't resolve this -- it just picks a side silently.
- **1,343 `(year, parent_number)` keys map to more than one gvkey**, resolved "keep first." That's a
parent-linkage ambiguity, unrelated to tickers, and it's ten times route C's size.

## Something I found while verifying, which matters more for your project

`gvkey 184254` carries 69,696 Redbox kiosks in 2017 -- that's **Apollo Global Management**, ticker APO.
Apollo bought Outerwall/Redbox in 2016, so the link is *correct* in ownership terms (in 2015 the same kiosks
sit under Outerwall, gvkey 065026). But it means a PE sponsor's "establishment footprint" is its portfolio
companies' locations. Any PE or holding-company gvkey will behave this way, and for a geography motive that's
a distortion worth a rule.

## Your Q1 is done

`ticker` is in the panel, populated on **100%** of rows -- taken from the parent map, so it's the firm's
ticker on every location, not just the HQ row. Panel is now 19,895,389 rows, 7,769 gvkeys, 696 MB.
      [action] AskUserQuestion:

--- AGENT   [2026-08-11 03:03:22] ----------------------------------------
Both questions answered, and the panel is final.

## Q1 -- `ticker` is in

Panel is now **19,895,389 rows / 7,769 gvkeys / 696 MB**, keyed on `gvkey` with `ticker` on **100% of rows**.
It's the *firm's* ticker pulled from the parent map, not just the HQ row's, so it's usable on every location.
`parent_number` stayed in the crosswalk -- say the word and it's one line to add.

## Q2 -- the size gap is mostly columns, not rows

Two separate things were compounding:

- **Rows: 21,183,487 -> 19,895,389, a 6.1% loss.** Decomposed: **6.1% whose ticker resolves to no gvkey**,
**0.01% missing coordinates.** Nothing else.
- **Bytes: 1.24 GB -> 696 MB.** The panel drops `address_line_1`, `city`, `parent_number`,
`subsidiary_number`, `business_status_code`, `year_established`. The two address strings are high-cardinality
and expensive, which is why the file nearly halves while the row count barely moves.

**So no -- gvkey doesn't cover all public firms, and that's mostly correct behaviour rather than a defect.**
30.7% of Infogroup's ticker *records* don't resolve, but only 6.1% of establishments, because the failures
concentrate in small firms. **88.6% of unresolved tickers are 4 characters** against 61.5% of resolved ones,
and the names are exactly what that implies: Apollo Bancorp, Ballston Spa Bancorp, Hamlin Bank & Trust,
Decker Manufacturing, Original Sixteen to One Mine. Small OTC and pink-sheet companies that simply aren't in
CRSP or Compustat, so no gvkey exists to find.
```

The part that *was* a defect

Buried in that unresolved list were Berkshire Hathaway, News Corp, Liberty Media, Moog, Crawford -- dual-class firms, dropped because the three sources spell share classes three different ways. Your exact-matching question landed right on it. Fixed with a class-variant fallback gated on >=0.90 name agreement, yielding **13 firms and 265,008 establishment-years**, every one listed in the README and flagged `match_source='share_class'` so you can drop them with one filter. Berkshire now runs all 28 years (1,946 establishments in 1997 to 12,503 in 2024).

I also verified the thing your question implied I should: **ticker collisions inside CRSP are 17 of 211,421 ticker-years, and zero after preferring common shares.** Exact matching isn't hiding ambiguity there. What it doesn't fix, and both are bigger than the fuzzy step: **3,959 ticker-years where CRSP and Compustat return different gvkeys** for the same exact ticker (CRSP kept), and **1,343 parent keys mapping to more than one gvkey** (keep-first).

One more thing found while verifying

Those 69,696 Redbox kiosks belong to `gvkey 184254` -- **Apollo Global Management**, which bought Outerwall in 2016. The link is right by ownership, and the panel tracks the handover correctly (Outerwall holds them in 2015). But it means a PE sponsor's establishment footprint is its portfolio companies' locations. Apollo would appear to have a presence in essentially every congressional district in the country. Any PE or holding-company gvkey in your donation sample needs a rule before the geography motive touches it -- recorded as the third project-side trap alongside the coverage gradient and the unstaffed-location problem.

Everything is committed: `establishment_footprints` (README with the full 13-firm audit table), `DATA_CATALOG.md`, and the project memo.

--- AUTHOR [2026-08-11 03:54:47] ----------
So what's the difference between infogroup_gvkey_establishments_1997_2024 and infogroup_public_establishments_1997_2024?

--- AUTHOR [2026-08-11 03:55:26] ----------
So what's the difference between infogroup_gvkey_establishments_1997_2024 and infogroup_public_establishments_1997_2024? Which one should I use for our political donation motive project?

--- AGENT [2026-08-11 03:55:40] ----------
Straight answer below, but one thing I should check first -- the public file has three columns the gvkey panel drops, and one of them may matter for your design.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common ↪ Dataset/Infogroup/establishment_footprints" && PYTHONIOENCODING=utf
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common ↪ Dataset/Infogroup/establishment_footprints" && PYTHONIOENCODING=utf
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common ↪ Dataset/Infogroup/establishment_footprints" && PYTHONIOENCODING=utf

--- AGENT [2026-08-11 03:56:52] ----------
`business_status_code` turns out to be worth having, so I'm adding it before answering:

code	meaning	share of ticker rows	share of other locations
1	headquarters	85.3%	0.02%
2	branch	0.45%	98.1%
3	subsidiary (Bloomingdale's, Burdine's)	3.7%	1.9%
9	single-location firm (Bank of Utica)	7.4%	0%
[action] Edit: G:\OneDrive - The Pennsylvania State University\PhD research projects\1.Common ↪ Dataset\Infogroup\establishment_footprints\code\2.match_establishments_
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common ↪ Dataset/Infogroup/establishment_footprints/code" && python -u 2.mat
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common ↪ Dataset/Infogroup/establishment_footprints" && python - <<'PY' p="R

--- AGENT [2026-08-11 03:58:31] ----------
The difference

They're the two stages of one pipeline. The public file is the raw catch; the gvkey panel is that catch with firm identifiers attached.

| | `..._public_establishments_...` | `..._gvkey_establishments_...` |

```
|---|---|---|
| What it is | every establishment of any ticker-bearing parent | the same, restricted to those that resolve
to a Compustat firm |
| Rows | 21,183,487 | 19,895,389 |
| Size | 1.24 GB | 697 MB |
| **`gvkey`** | **no** | **yes** |
| `is_hq`, `match_source` | no | yes |
| `address_line_1`, `city` | yes | no |
| `parent_number`, `subsidiary_number`, `year_established` | yes | no |

The 6.1% row gap is entirely firms whose ticker resolves to no gvkey (plus 0.01% missing coordinates). The
much larger size gap is the two street-address string columns.

## Use the gvkey panel

Not a close call, for three reasons:

1. **Your donation sample is keyed on gvkey.** The public file has no gvkey, so you'd have to redo the
ticker->CRSP->CCM->Compustat match yourself to join anything.
2. **The 6.1% it drops are exactly the rows this project cannot use.** Those are small OTC and pink-sheet
firms with no gvkey -- Apollo Bancorp, Bank of Utica, Original Sixteen to One Mine. They can never appear in
a Compustat-based donation sample, so the panel loses nothing you could have used.
3. **`is_hq` is only in the panel**, and it's what answers your HQ-district question.

I just moved the one column worth rescuing. `business_status_code` is now in the panel (22 columns, 697 MB)
-- it separates headquarters from branches from subsidiaries from single-location firms, which is a filter
your geography motive will likely want, and `is_hq` alone doesn't give you it (only 85.3% of ticker records
are Infogroup's designated HQ).

**Nothing else in the public file is worth going back for.** `year_established` is populated on 1.4% of rows,
`subsidiary_number` carries the same all-zeros sentinel that nearly broke the parent match, and lat/long
beats a street address for district assignment anyway. Keep the public file as the reproducible intermediate
-- it's what lets step 2 rerun in 41 seconds instead of 13 minutes -- but read from the panel.

## One thing this settles that you'd otherwise have to worry about

**Closed establishments aren't a contamination problem.** Each archive year is an independent snapshot of
operating businesses, so a plant that shuts simply stops appearing in the next year -- absence *is* the
signal. There's no defunct-location flag to apply and no stale-footprint filter to build. That interacts well
with your even-year rule: reading a cycle's own archive year gives you the locations operating in that cycle,
nothing carried forward.

--- AUTHOR  [2026-08-11 04:07:14] ----------------------------------------
One question before we use the infogroup_gvkey_establishments_1997_2024 sample for our political donation
motive project: so we have latitude, longitude, and zipcode of establishments in the
infogroup_gvkey_establishments_1997_2024 data? I plan to use only even year snapshot as the location of
establishments for different cycles. Do you think this approach sound reasonable? Is there dataset that
allows us to use latitude and longitude to assign the a place to a district or we need to use zipcode to
assign the district to different establishments?

--- AGENT   [2026-08-11 04:07:46] ----------------------------------------
Three good questions. Let me check the first two directly and test the third empirically.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
      ↪  Dataset/Infogroup/establishment_footprints" && PYTHONIOENCODING=utf
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
      ↪  Dataset/Politics" && echo "=== shapefiles anywhere in Politics? ===

--- AGENT   [2026-08-11 04:08:23] ----------------------------------------
No shapefiles locally -- but you've already built cycle-keyed ZIP->CD crosswalks, including a folder marked
"Wrong data (not map yr t,t+1 CD-ZIP back to yr t-1 cycle)", so you've already settled the vintage question
once. Let me look at what you built.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
      ↪  Dataset/Politics/1.CD_ZIP Crosswalk/Final 2004-2024 zip_district_li

--- AGENT   [2026-08-11 04:08:43] ----------------------------------------
That's exactly the right input. Now the decisive test -- with ~70 establishments per firm and ZIPs straddling
districts, does "firm has an establishment in the candidate's district" stay informative or fire almost
everywhere?
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" &&
      ↪  PYTHONIOENCODING=utf-8 python - <<'PY' import pandas as pd, glob, os, py
```

```
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" &&
      ↪  PYTHONIOENCODING=utf-8 python - <<'PY' import pandas as pd, glob, os, py

--- AGENT   [2026-08-11 04:10:21] ----------------------------------------
Answering your clarified question first, then finishing the test.

**Yes -- Census TIGER/Line congressional district shapefiles.** They're free, public, and published per
Congress:

- `https://www2.census.gov/geo/tiger/TIGER{year}/CD/` -- e.g. `tl_2012_us_cd112.zip`. Vintages run cd106
(1999) through cd119, so every cycle you need, 2000-2024, has a matching map.
- For anything earlier or for a single consistent series, the **UCLA/Lewis et al. historical district
shapefiles** (`cdmaps.polisci.ucla.edu`) cover 1789-2013.
- **IPUMS NHGIS** redistributes the same boundaries with cleaner vintage labels.

The mechanics are a point-in-polygon join -- `geopandas.sjoin(points, districts, predicate="within")` -- and
geopandas 1.1.3 and shapely 2.1.2 are already installed on this machine, so nothing new to set up. It would
assign each establishment to exactly one district instead of a set.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" &&
      ↪  PYTHONIOENCODING=utf-8 python - <<'PY' import pandas as pd, glob, os, py

--- AGENT   [2026-08-11 04:11:34] ----------------------------------------
Test is done, and it changes the design picture. Let me record it before I lose the numbers.
      [action] Edit: G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI -
      ↪  Political Donation Motive\STATUS_MEMO.md
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && git add -A && git commit -q -m "S

--- AGENT   [2026-08-11 04:12:22] ----------------------------------------
## 1. Yes -- all three, on every row

| field | coverage |
|---|---|
| `latitude`, `longitude` | 100.00% |
| `zipcode` (5-digit) | 100.00% |
| `state`, `fips_code` | 100.00% |
| `county_code`, `census_tract`, `cbsa_code` | 99.9% |

## 2. Lat/long -> district: yes, several sources

As above -- **Census TIGER/Line** (`www2.census.gov/geo/tiger/TIGER{year}/CD/`, vintages cd106-cd119, so
every cycle 2000-2024 is covered), **UCLA/Lewis** for the long historical series, or **IPUMS NHGIS**.
Point-in-polygon via `geopandas.sjoin`, and geopandas is already installed here.

It's worth doing: **18.6% of ZIP-cycles in your crosswalk map to more than one district**, so the ZIP route
inflates every firm's district set the same way it inflates HQ. But I have to be straight with you -- it is
not what makes or breaks this measure. See below.

One consistency point if you go that way: `hq_cd_label` in the trial sample came from the ZIP crosswalk, so
switching establishments to coordinates would measure the two geographies by different rules. Rebuild the HQ
side the same way if you switch.

## 3. Even-year rule: sound, and I can put a number on it

Comparing each cycle's own archive year against the preceding odd year, for the 599 sample firms: the
district **set** is identical for only 14.3% of firm-cycles, but **the binary district match flips on just
6.0% of donation rows.** So the choice is defensible and barely moves anything.

One correction to the reasoning, though: most of that set instability is **Infogroup coverage churn** --
locations entering and leaving the archive between vintages -- not firms relocating. The even-year snapshot
is still the right pick, but the good reason is that it's the vintage closest to the election-date cutoff you
already adopted, not that it removes relocation bias.

## The thing you should see before designing the measure

I ran your crosswalk against the panel to size the category, and it doesn't survive in its naive form:

| establishment filter | median districts covered | "candidate's district" hit rate |
|---|---|---|
| **all locations** | **57** | **33.0%** |
```

```
| >=10 employees | 34 | 25.1% |
| >=50 employees | 15 | 15.2% |
| >=250 employees | 5 | **6.5%** |
| *HQ only (current)* | *1-4* | *3.9%* |

A typical sample firm has establishments in **57 of 435 districts**. Counting any of them makes geography
fire on **a third of all donations**, against 3.9% today. That converts geography from the scarce,
informative category it is in v1/v2 into the largest category in the taxonomy -- and it would fire on firms
that have a UPS drop box in the district.

**Materiality is the lever, not geocoding.** An employment threshold does far more than point-in-polygon:
>=250 employees brings it to 6.5% and a median of 5 districts, which is the range where "the firm has a real
presence in this district" means something. That's the parameter to think about, and it's a judgment call
about what counts as an establishment worth donating over -- a 400-person plant, plausibly; a franchise
counter, no.

Worth deciding before anything gets built, since the threshold defines the category rather than tuning it.

--- AGENT [2026-08-11 04:39:04] ----------
Validation done. **They're comparable -- good enough to use, with one caveat that's about the ticker link rather than the HQ.**

Coverage

Your 10-X file has 124,186 gvkey-years / 12,888 gvkeys (2000-2024). Overlap with the Infogroup HQ record: **75,326 gvkey-years, 6,371 gvkeys** -- 60.7% of your rows, 76.5% of Infogroup's. The shortfall is the ticker-coverage gradient, not a matching failure.

Agreement

	all	2000-04	2010-14	2020-24
state exact	**95.8%**	92.8%	96.4%	96.7%
ZIP5 exact	**84.9%**	72.6%	86.3%	89.8%
ZIP3 (metro)	**92.7%**	87.5%	93.5%	94.5%

And at the level this project actually needs -- **the two sources put the firm in the same congressional district set 91.3% of the time**, 94.4% overlap at all, only **5.6% land somewhere the other doesn't touch**. Where ZIP5 differs, the median gap is **9.4 km** and 65.4% are within 25 km, so **HQs agree or are within 25 km on 94.8% of gvkey-years**.

Agreement improving steadily over time matches everything else we've seen about Infogroup's coverage.

The big disagreements aren't errors -- they're two different constructs

The worst cases are systematic, not random:

- **Fairchild Semiconductor**: files from San Jose, Infogroup reads South Portland, Maine -- where the fab is.
- **Contango ORE**: files from Houston, Infogroup reads Fairbanks -- where the mine is.

The 10-X header is the **filing address**; Infogroup's is the **operating headquarters**. For a geography motive about where a firm's people and plants sit, Infogroup's is arguably the better construct -- which is worth deciding deliberately rather than treating the 10-X as ground truth and Infogroup as noise.

One caution, and a correction to my own first read

Company names disagree on 9.15% of gvkey-years, which looked alarming until I checked what was in it: **Compustat's `conm` is the firm's *current* name, Infogroup's is the name in that archive year.** So NPK International/Newpark, BXP/Boston Properties, U-Haul Holding/AMERCO, Logility/American Software all read as mismatches and are the same firm. **A name mismatch is not evidence of a bad link.**

Requiring a name *and* state mismatch narrows it to **1.41% (328 gvkeys)** -- and even most of those are genuine mergers and renames that moved the HQ (Six Flags/Cedar Fair, Columbia Banking/Umpqua, DuPont/Dow).

What survives is a small residue of **true ticker-reuse errors, caused by Infogroup carrying a stale ticker**:

- gvkey 038722 (**Stem Inc**) picks up **Microbot Medical**, which still shows the `STEM` ticker its predecessor StemCells used.
- gvkey 039665 (**Theseus Pharmaceuticals**, `THRX` from 2021) picks up **Innoviva**, which used `THRX` as Theravance until 2016.

This is the answer to your earlier exact-matching question, arriving from the other direction: year-bounding the *Compustat* side doesn't defend against staleness on the *Infogroup* side. True rate is well under 1.4%, and the name-plus-state disagreement flag is a ready screen if you want a clean subsample.

Both repos committed; the README and status memo carry the full numbers.

--- AUTHOR [2026-08-11 04:53:30] ----------
1. I think historical name is ok and even better. 2. So it seems that it's better to use Infogroup HQ data rather than 10-X file one? And then we directly use Census TIGER/Line (www2.census.gov/geo/tiger/TIGER{year}/CD/, vintages cd106-cd119 to add the district information for both HQ and estbalishment for cycles 2000-2024? Would this way give the best matching result?

--- AGENT [2026-08-11 04:54:10] ----------
Both are good questions, and the second one has a hidden dependency I should test before saying yes: **point-in-polygon only beats the ZIP crosswalk if the coordinates are actually rooftop-level.** If Infogroup geocodes to ZIP centroids, you'd get the same answer with extra steps.

```
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
      ↪  Dataset/Infogroup/establishment_footprints" && PYTHONIOENCODING=utf

--- AGENT   [2026-08-11 04:55:00] ----------------------------------------
Coordinates are 5-6 decimals (~1 m), and the big clusters are real co-location -- ZIP 92802 is Disneyland,
32830 is Walt Disney World. So the precision is genuine, not centroid fallback. Now let me verify my earlier
claim about TIGER vintages before you act on it.
      [action] ToolSearch: select:WebFetch
      [action] WebFetch: https://www2.census.gov/geo/tiger/
      [action] WebFetch: https://www2.census.gov/geo/tiger/TIGER2012/CD/

--- AGENT   [2026-08-11 04:55:47] ----------------------------------------
That changes my earlier advice, so let me pin it down -- **TIGER2012 contains `cd112`, not `cd113`**, i.e.
the Congress *sitting* that year, not the one elected.
      [action] WebFetch: https://www2.census.gov/geo/tiger/PREVGENZ/cd/
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && cat >> STATUS_MEMO.md <<'EOF'  ##

--- AGENT   [2026-08-11 04:57:56] ----------------------------------------
## 1. Historical name

Agreed -- and it's the better property for this project, since you want to know what the firm was called *at
the time of the donation*. The only consequence is diagnostic: a name mismatch against Compustat's `conm` is
now expected rather than suspicious, so it can't be used on its own as a link-quality flag. Name **and**
state disagreement together still works.

## 2. HQ source -- I'd say no, keep the 10-X file

The agreement numbers argue *for* Infogroup, but coverage argues against, and coverage wins here:

| | 10-X header file | Infogroup HQ |
|---|---|---|
| gvkeys | **12,888** | 6,371 (overlapping) |
| gvkey-years | **124,186** | 98,424 |
| coverage over time | flat | **31% of listed firms in 1997 -> 61% in 2024** |

The HQ-based geography category is currently the one measure in your taxonomy **without** a coverage
gradient. Switching its source would import one -- in exchange for a 91.3% district agreement, which isn't a
gain at all since the two mostly say the same thing.

So: **10-X/Compustat historical HQ stays primary. Infogroup supplies establishments.** Infogroup's HQ is
already inside the establishment panel as `is_hq`, so an establishment-in-district test picks it up anyway,
and you can use it as an operating-HQ robustness check where the legal/operating distinction matters
(Fairchild's San Jose filing address vs. the South Portland fab).

## 3. TIGER -- yes, but I need to correct what I told you earlier

**`TIGER{Y}/CD/` contains the Congress *sitting* in year Y, not the one elected in it.** I verified:
`TIGER2012/CD/` holds `tl_2012_us_cd112.zip` -- the 112th, i.e. the *pre*-2010-redistricting map. The
districts actually contested in the 2012 cycle are the 113th's.

So for cycle *Y*, the file you want is **`TIGER{Y+1}` -> `cd{107 + (Y-2000)/2}`**. Using TIGER2012 for cycle
2012 would assign every firm to maps that weren't on the ballot -- and 2012 and 2022 are exactly the
redistricting years where it matters most.

My "cd106-cd119 all in TIGER" was also wrong on availability. It's split across two Census locations:

| cycles | Congress | source |
|---|---|---|
| 2000-2006 | cd107-cd110 | `www2.census.gov/geo/tiger/PREVGENZ/cd/cd1NNshp/` (carries cd103-cd110) |
| 2008-2024 | cd111-cd119 | `www2.census.gov/geo/tiger/TIGER{Y+1}/CD/` |

Both public, different formats and naming conventions -- budget some cleanup.

## Would this give the best matching result?

**The most precise, yes. The best, only partly** -- and I want to be straight about which constraint is
binding.

Point-in-polygon is a genuine improvement: 18.6% of ZIP-cycles map to multiple districts, so the ZIP route
```

inflates every firm's district set and forces the 2-4 district ambiguity on 39% of HQs. Coordinates remove that, and Infogroup's are real -- 5-6 decimals, and the big same-coordinate clusters are true co-location (ZIP 92802 is Disneyland, 32830 Walt Disney World), not centroid fallback.

But precision isn't what's limiting this measure. **The establishment hit rate is 33% because large firms genuinely operate in 57 districts, not because ZIPs are ambiguous.** Point-in-polygon might shave that to the high 20s. The materiality threshold moves it from 33% to 6.5%. If you do one thing, do the threshold.

The honest ordering:

1. **Decide the materiality threshold** -- defines whether the category exists at all.
2. **Decide the missing-data rule** for the coverage gradient (36.7% of cycle-2000 rows have a footprint vs 96.2% in 2022).
3. **Then** TIGER point-in-polygon, which sharpens a measure whose character is already set by 1 and 2.

One caveat on doing HQ and establishments the same way: the 10-X file has no coordinates, only ZIP. So if you keep it as the HQ source, HQ stays on the ZIP crosswalk while establishments move to polygons -- a measurement asymmetry you'd need to state, or resolve by geocoding the 10-X addresses.

--- AUTHOR [2026-08-11 05:10:07] ----------
Want to confirm one thing: so " cycles | Congress | source
|
+-----------+-------------+---+
| 2000-2006 | cd107-cd110 | www2.census.gov/geo/tiger/PREVGENZ/cd/cd1NNshp/ (carries cd103-cd110) |
+-----------+-------------+---+
| 2008-2024 | cd111-cd119 | www2.census.gov/geo/tiger/TIGER{Y+1}/CD/ |" will
give a latitude, longitude level matching when we use the Infogroup data?

--- AGENT [2026-08-11 05:10:31] ----------

↪ Political Donation Motive" && cat >> STATUS_MEMO.md <<'EOF' **

--- AGENT [2026-08-11 05:12:18] ----------
Yes -- mechanically, all of those are polygon shapefiles, so `geopandas.sjoin(points, districts, predicate="within")` with Infogroup's lat/long gives you exactly one district per establishment. That's true point-in-polygon assignment, not a ZIP lookup.

But the two halves of that table are **not equal quality**, and I should have flagged it when I wrote it.

PREVGENZ is the *generalized* series

GENZ = GENeraliZed -- simplified boundaries built for small-scale mapping, not full-resolution TIGER/Line. The file sizes give it away:

file	coverage	size
`cd99_110_shp.zip` (PREVGENZ, national)	all US districts, 110th	**4.5 MB**
`tl_2012_us_cd112.zip` (TIGER, national)	all US districts, 112th	**45 MB**

Ten times the detail for the same geography. Generalized boundaries are smoothed, so an establishment sitting near a district line can land on the wrong side of it. Still much better than the ZIP crosswalk -- you get one district instead of a set of 2-4 -- but it isn't the precision the later years give you.

Full resolution reaches further back than I said

`TIGER2010/CD/` has `108/` and `111/` subdirectories, so:

cycles	Congress	source	resolution
2002	cd108	`TIGER2010/CD/108/`	**full**
2008	cd111	`TIGER2010/CD/111/`	**full**
2010-2024	cd112-cd119	`TIGER{Y+1}/CD/`	**full**
2000, 2004, 2006	cd107, cd109, cd110	`PREVGENZ/cd/cd1NNshp/`	**generalized**

So only three cycles are stuck with generalized boundaries, not four.

```
## The thing to carry into the design

Geocoding precision is **worse in the early cycles** (generalized boundaries for 2000, 2004, 2006).
Infogroup's firm coverage is **also worse in the early cycles** (36.7% of cycle-2000 donation rows have a
footprint vs 96.2% in 2022).

Both measurement artifacts push the same direction. **Any time trend you find in an establishment-based
geography motive would be partly measurement, not behaviour** -- and your sample already has the committee
share trending the same way. That's an argument for restricting the establishment test to later cycles rather
than trying to correct for it.

## Practical gotchas when you build it

- **CRS**: TIGER is NAD83 (EPSG:4269), Infogroup is WGS84 -- about a metre in CONUS, immaterial here, but set
it explicitly so geopandas doesn't warn or silently mismatch.
- **The district field is renamed every vintage**: `CD107FP`, `CD112FP`, ... `CD119FP`. The loader needs
per-vintage handling.
- **File layout differs**: PREVGENZ ships per-state `cd{ss}_{NNN}_shp.zip` plus a national `cd99_*`;
TIGER2010 nests per-state files under a Congress subdirectory; TIGER2012+ has a single national
`tl_{Y}_us_cd{NNN}.zip`.
- **At-large states** code district as `00` or `98`, and DC/territories need a rule -- your crosswalk's
district numbering has to line up with DIME's `cand_office_district`.

Recorded in the memo with the size evidence, so the next session doesn't re-derive it.

--- AGENT   [2026-08-11 05:47:41] ----------------------------------------
Merge validated: **706 polygon parts -> 437 districts**, and the state counts are right for the 107th (CA 52,
NY 31, TX 30, FL 23, PA 21). Registering the asset in the catalog while downloads continue.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
      ↪  Dataset" && git -C Politics rev-parse --is-inside-work-tree 2>/dev/

--- AGENT   [2026-08-11 05:48:13] ----------------------------------------
The download is running in the background and will take roughly another **90 minutes** -- Census serves these
at about one state file per 20 seconds, and four of the vintages ship per-state (57 + 56 + 56 + 56 files)
rather than as a single national zip.

## Where it's going

```
1.Common Dataset\Politics\1.CD Boundary Shapefiles\
  code\download_cd_shapefiles.py    rerun to refresh; --merge to re-merge only
  raw\cd{NNN}\                      Census zips exactly as distributed
  merged\cd{NNN}.gpkg               one national GeoPackage per Congress  <- use these
  README.md
```

Registered in `DATA_CATALOG.md` so it's findable from other projects.

Two things I found while building it

PREVGENZ ships no `.prj` file -- only `.shp/.dbf/.shx`, so geopandas reports `crs=None`. A
point-in-polygon join against that would either fail or silently compare unprojected coordinates. The merge
now assigns EPSG:4269 (NAD83) explicitly, which is what Census documents for these.

The files have one row per polygon *part*, not per district. cd107 arrives as **706 rows for 437
districts**, because islands and detached pieces are stored separately. The merge dissolves on state x
district. Validated on cd107: 437 districts, and the state counts are exactly right for the 107th -- CA 52,
NY 31, TX 30, FL 23, PA 21.
```

The cycle->file mapping, now in the README

cycle	Congress	file	resolution
2000-2006	107-110	`cd107`-`cd110`	**generalized**
2008-2018	111-116	`cd111`-`cd116`	full
2020	*117 -> 116*	**`cd1162`**	full
2022-2024	118-119	`cd118`, `cd119`	full

There is no cd117 and that's correct -- the 117th Congress ran on the 116th's districts, since post-2020 redistricting first applied to the 118th. Both TIGER2021 and TIGER2022 carry cd116. Cycle 2020 uses `cd1162.gpkg`, the TIGER2021 vintage, which is cd116 *plus* the court-ordered redraws after 2018 (North Carolina). So cycle 2018 -> `cd116`, cycle 2020 -> `cd1162`.

I'll run the merge step once downloads finish and report the district counts per Congress as a check -- 435 voting districts plus DC and territories, with the apportionment shifting at 2002 and 2012 exactly as it should.

--- AUTHOR [2026-08-11 05:50:58] ----------
1. For cd107-cd110, would it be better to use generalized resolution or match the location based on zip-cd crosswalk files? 2. I feel it may not be correct to consider all establishment locations when evaluating geography donation motive. What will be a good cutoff to consider only certain establishments for a firm?

--- AGENT [2026-08-11 05:51:41] ----------
Both are design questions where I'd rather show you numbers than reason in the abstract. Let me run Q2 properly first, since it decides whether the category exists.

--- AGENT [2026-08-11 05:53:47] ----------
Downloads at cd111 (21/56); still roughly 75 minutes out.

Q1 -- use the generalized shapefiles, not the ZIP crosswalk

Three reasons, in increasing order of importance:

1. **One district per point instead of a set.** The ZIP route returns 2+ districts for 18.6% of ZIP-cycles and forces an arbitrary allocation -- in the analysis below I had to split each establishment's employment evenly across the districts its ZIP touches, which is a fudge with no justification behind it.
2. **The error geometry is smaller.** Generalized boundaries are displaced near district lines only, on the order of hundreds of metres. ZIP ambiguity spans the whole ZIP -- kilometres to tens of kilometres in rural areas -- and hits *every* establishment in a straddling ZIP, not just those near a line.
3. **Definitional consistency across the panel.** This is the real argument. If 2000-2006 uses ZIP and 2008+ uses polygons, your measure changes definition at exactly the point where Infogroup coverage and boundary precision already improve. You'd bake a structural break into the series at 2008 and never be able to separate it from behaviour.

And this is testable rather than arguable. `cd108` exists in *both* forms -- generalized in PREVGENZ, full resolution in `TIGER2010/CD/108/`. Downloading the full-res version (~20 min) would let me measure directly: what share of establishments does the generalized file assign to a different district than full resolution, and what share does the ZIP crosswalk get wrong against the same benchmark. That settles Q1 with data. Say the word and I'll queue it.

Q2 -- threshold at the district level, not the establishment

First, the construction point: **aggregate to the district before thresholding.** Thirty stores in one district may total 600 jobs where no single store passes any bar. The unit that matters is the firm's presence in the district.

Here's the menu, all on your 1,000-row sample (HQ-only benchmark = 2.3% under this method, 3.9% in the current sample):

rule	hit rate	median districts/firm
all establishments	33.0%	56
jobs in district >= 250	9.6%	5
jobs in district >= 500	**5.3%**	3
jobs in district >= 1000	2.5%	2
district >= 5% of firm employment	5.4%	3
district >= 10% of firm employment	3.3%	2
top-3 districts by employment	4.5%	3
share >=5% **and** jobs >=250	4.0%	3

My recommendation: absolute jobs >= 500 as the primary, not a share-based rule -- and the reason is specific to your data problem.

A share rule needs the *denominator* -- the firm's total footprint -- to be correctly measured. Infogroup's coverage is incomplete and improves over time, so every share is computed on a partial footprint and the bias trends with the calendar. The absolute rule only needs the establishments *in that district* to be captured; it never touches the firm's total. Given that the coverage gradient is this measure's known weak point, don't build a construction that compounds it.

The trade-off is that an absolute rule isn't scale-free -- it favours large firms. That's a real cost, and it's why the share rule belongs in robustness rather than nowhere.

The reassuring part: four quite different constructions -- absolute >=500 (5.3%), share >=5% (5.4%), top-3 (4.5%), the combined rule (4.0%) -- all land between 4% and 6%, close to the HQ benchmark. The category's size is not an artifact of which rule you pick, as long as you pick something restrictive. That's a robustness table that writes itself.

One addition I'd make: count the HQ district regardless of headcount. A headquarters is politically salient through executive presence and civic profile even when employment is modest, so the natural construction is `HQ district ? districts passing the threshold`.

What not to do: don't tune the threshold to make the hit rate look right. Pick >=500 on the reasoning above, show the full ladder as robustness, and let the reader see the measure isn't sensitive to it.

--- AGENT   [2026-08-11 06:14:49] ----------------------------------------
Fixed and resumed. What happened:

**cd107-cd116 all downloaded fine.** The job died on cycle 2020's file because I'd assumed `TIGER2021/CD/`
was per-state like TIGER2023 and TIGER2025. It isn't -- it carries a single national `tl_2021_us_cd116.zip`
(39.8 MB), and my regex only matched per-state names, so it found nothing and exited rather than downloading
the file sitting right there.

Two changes: cd1162 is now declared national, and `state_zips()` matches both `tl_{Y}_{ss}_cd{NNN}.zip` and
`tl_{Y}_us_cd{NNN}.zip` so the same assumption can't bite on a future vintage. Already-downloaded files are
skipped on resume, so it picked up where it left off.

Remaining: cd1162 (one national file), then cd118 and cd119 (56 per-state files each, ~20 min apiece), then
the merge across all thirteen. I'll report the district counts per Congress when it lands -- that's the check
that the apportionment shifts at 2002 and 2012 the way it should.

The two design answers in my previous message stand and don't depend on this finishing.

What's on disk

`1.Common Dataset\Politics\1.CD Boundary Shapefiles\` -- thirteen national GeoPackages, `cd107` through `cd119`, one per Congress, covering every cycle 2000-2024. Normalised `cd_congress` / `cd_statefp` / `cd_district`, dissolved to one row per district, CRS set. Raw Census zips kept alongside, plus a rerunnable script and README. Registered in `DATA_CATALOG.md`.

Two checks, both passed

Apportionment reproduces exactly -- the cheapest test that each file is the map it claims to be:

	cd107	cd108	cd112	cd113	cd118
CA	52	53	53	53	**52**
NY	31	**29**	29	**27**	**26**
TX	30	**32**	32	**36**	**38**
PA	21	**19**	19	**18**	**17**

Every shift matches the 2000, 2010 and 2020 reapportionments, including California's first-ever seat loss in 2022.

End-to-end, 807,827 Infogroup establishments in 2012 joined to `cd113`: **100.00%** received a district, and **99.6%** of those fall inside the ZIP crosswalk's set for the same point. The two methods agree.

This strengthens my Q1 answer considerably

I told you 18.6% of ZIP-cycles straddle districts. That understates the problem badly, because it weights every ZIP equally. Weighted by **where establishments actually are**:

- Only **37.1%** of establishments have an unambiguous ZIP.
- **62.9%** sit in a ZIP the crosswalk maps to two or more districts.

Businesses concentrate in dense, multi-district ZIPs. So the ZIP route leaves nearly two-thirds of your establishments ambiguous, and point-in-polygon resolves all of them while agreeing with the ZIP set 99.8% of the time when it picks. **Use the shapefiles for all cycles, generalized ones included** -- the generalized boundaries' error is confined to points near district lines, whereas ZIP ambiguity affects 63% of establishments outright.

One consequence you should know about

The threshold menu I gave you needs recomputing. Those numbers -- 33.0% unrestricted, 5.3% at >=500 jobs -- came from the ZIP route, which credits an establishment to *every* district its ZIP touches. With 63% of establishments ambiguous, that inflated every firm's district set, and I split employment evenly across straddled districts to compensate, which was a fudge. Under point-in-polygon each establishment lands in one district, so both the district counts and the hit rates will come down. The *ranking* of the rules should survive; the levels won't.

I'd recompute the menu on polygons before you fix a threshold. That's maybe fifteen minutes of work now that the shapefiles exist -- say the word.

Two bugs worth remembering, both caught by checking rather than by the code failing loudly: PREVGENZ ships no `.prj` (CRS came back `None`), and these files carry one row per polygon *part* -- cd107 arrives as 706 rows for 437 districts.

--- AUTHOR [2026-08-11 06:29:45] ----------
OK. You can recompute the menu on polygons. After it, you can do the following things to create the sample: 1. I aggree to use use the generalized shapefiles, not the ZIP crosswalk. 2. I aggre to have thresholds at the district level, not the establishment. Let's use jobs in district >= 250 for establishment to be considered. All HQ location will be considered but we use zip-cd crosswalk + 10-X HQ for the cycle-gvkey-HQ-cd rows because the 10-X HQ information has more data point and it only has ZIP information. So the final sample is the current HQ-CD data + newly created selected establishment-CD data at the GVKEY and cycle level. You can save final sample in \2026.07 AI - Political Donation Motive\Data and code to create the sampe in \2026.07 AI - Political Donation Motive\Code.

## The menu on polygons -- my caveat was overcautious

The levels barely moved from the ZIP version: unrestricted 33.0% -> 29.3%, **>=250 jobs 9.6% -> 9.0%**, >=500
5.3% -> 5.4%. The ranking is identical. The earlier menu was sound.

## What's on disk

`Data\firm_cycle_district_2000_2024.parquet` and `.dta` (labelled variables, Stata-ready), built by
`Code\2.build_firm_district_panel.py`.

**325,597 firm-cycle-district rows, 12,516 gvkeys, cycles 2000-2024.** One row per gvkey x cycle x district,
with `in_hq` and `in_estab` as separate flags plus `estab_jobs`, `n_estab`, `hq_zip`, `hq_cd_n`, `cd_label`,
and a `source` field:

| source | rows |
|---|---|
| establishment only | 234,051 |
| HQ only | 75,290 |
| both | 16,256 |

Median 2 districts per firm-cycle.

## Match rates on your 1,000-row sample

| | rate |
|---|---|
| HQ district | **3.5%** |
| establishment (>=250 jobs) | **9.0%** |
| **either** | **11.3%** |
| establishment adds beyond HQ | **+7.8pp** |

The HQ figure of 3.5% against the sample's own `hq_cd_match_cand` of 3.9% is a useful check -- the
```

reconstruction lines up with what's already in the trial sample.

Your HQ decision solved the coverage gradient. 94-100% of donation rows in every cycle now have their firm in the panel, against 36.7% in cycle 2000 when the footprint had to come from Infogroup alone. That was the single biggest threat to this measure and it's largely gone. `in_estab` alone still trends (2.2% in 2000, 13.7% in 2014, 5.1% in 2022); `in_hq` does not.

One problem the threshold doesn't solve

McDonald's (gvkey 007154) is in all 436 districts, every cycle -- median 1,170 employees per district, minimum 432. That's not an error: ~13,000 US restaurants genuinely put 250+ employees in every district. Best Buy, Target, Gap, FedEx, Cendant, Wendy's and Berkshire do the same. **50 gvkeys exceed 200 districts.**

The 250-job threshold answered "is this establishment big enough to matter." It doesn't answer "is this district *distinctive* for this firm." A firm present everywhere has no particular geographic tie to any candidate -- so every McDonald's donation would be labelled `geography`, and these ubiquitous chains are heavy donors.

I didn't fix it, because the threshold was your call and this is a separate decision. Three options, in ascending order of how much they change the construct:

1. **Ubiquity cap** -- set `in_estab = 0` for firm-cycles in more than ~50 districts. Removes about 50 gvkeys, leaves everything else untouched.
2. **Require top-k by employment** as well as >=250 jobs. Scale-free, but reintroduces dependence on the firm's footprint being completely observed.
3. **District share of firm employment above a floor.** Same dependence, and the coverage gradient bites hardest here.

I'd take option 1 -- it's the narrowest fix for the specific defect and doesn't reintroduce the denominator problem you avoided by choosing an absolute threshold. Worth settling before `in_estab` feeds any classification, and recording it in `taxonomy_decisions.md` as part of the geography rule rather than as a filter buried in code.

--- AGENT [2026-08-11 13:30:29] ----------
1. What "both" means

`source` records *why* a district is in the panel for that firm-cycle:

value	meaning	rows
`estab`	establishments employ >=250 there, but it's not the HQ district	234,051
`hq`	the 10-X headquarters ZIP maps here, but establishments don't reach 250	75,290
`both`	**the HQ is here *and* establishments employ >=250**	**16,256**

So `both` is the strongest form of geographic presence -- headquarters plus real employment. Median 721 jobs across 5 establishments in those districts.

The `hq`-only rows split about evenly into two quite different cases, which is worth knowing before you use them:

- **46.7%** are firms Infogroup doesn't cover that cycle at all -- no footprint exists to test.
- **53.3%** are firms Infogroup *does* cover, whose HQ district simply has fewer than 250 employees.

Those aren't interchangeable. The first is missing data; the second is a real measurement that came in below

threshold. Only 17.8% of HQ districts clear 250 jobs, which is itself informative -- most headquarters are modest employers.

2. I'd use 500

	>=250	>=500
gvkeys in >200 districts	**50**	**22**
districts per firm-cycle (median / p90)	2 / 17	2 / 11
establishment hit	9.0%	5.4%
either, with HQ	11.3%	8.0%
donation size, matched vs not	$2,000 vs $2,000, p=0.26	$2,500 vs $2,000, p=0.18
3rd+ cycle rate, matched vs not	32.2% vs 21.1%, **p=0.022**	38.9% vs 21.1%, **p=0.004**

The deciding evidence is that **discrimination improves at the higher threshold.** The persistence gap widens from 11.1pp to 17.8pp and the p-value falls fivefold. If the marginal 250-499 districts were genuine geographic ties, adding them shouldn't dilute the association -- but they do, which says those districts are mostly noise.

Two secondary points in the same direction: it halves the ubiquity problem (50 -> 22 firms in more than 200 districts), and it keeps geography scarce at 8.0% including HQ, nearer the 3.9% the category occupies in v1/v2.

Held to your own standard, that persistence result is suggestive, not a keeper. 54 matched rows against 90, one test among several I ran in the same session, and the donation-size difference is insignificant at both thresholds. It should be re-run on the full sample before it carries weight. I'd take 500 on the combination of that evidence and the ubiquity reduction, not on the p-value alone.

No rebuild needed to switch. `estab_jobs` sits on every row and the file's floor is 250, so `estab_jobs >= 500` gives you the tighter rule directly. Only going *below* 250 would require regenerating.

And whichever you pick, the ubiquity screen is still needed on top -- McDonald's clears 500 in every district too, so the maximum stays 436 either way.

--- AUTHOR [2026-08-11 13:34:48] ----------
1. Ok, let's use 500 as the threshold. 2. Just want to confirm: cycles correspond to incoming congress and the snapshot of establishments and HQs we use is the even year of that cycle, right?

--- AGENT [2026-08-11 13:35:19] ----------
Both confirmed -- and on (2) there's a deliberate asymmetry with the committee convention that I want to make explicit, since it looks like an inconsistency.

--- AGENT [2026-08-11 13:37:57] ----------
1. Rebuilt at 500

`in_estab` now means **>=500 jobs in the district**. I kept the rows down to 250 rather than dropping them, flagged `in_estab_250`, so the looser cut stays available as a robustness check with no rebuild -- and `source` marks them `estab_below_rule` so they can't be mistaken for qualifying rows.

source	rows
`estab` (>=500, not HQ)	109,514
`hq` (no qualifying establishments)	80,772
`both`	10,774
`estab_below_rule` (250-499, retained)	124,537

Geography under the rule -- `in_hq | in_estab` -- is 8.0% of donation rows, against 3.9% for the HQ-only measure currently in the trial sample. Median 2 districts per firm-cycle, p90 down from 17 to 11.

Still outstanding: **22 gvkeys exceed 200 districts.** The ubiquity screen isn't affected by the threshold change.

2. Yes on both -- and the asymmetry is intentional

Cycles map to the incoming Congress. Cycle 2012 -> the 113th, seated January 2013. That's what the shapefile selection implements: cycle 2012 uses `cd113`, not `cd112`.

Both snapshots are the cycle's own even year -- Infogroup archive year 2012 for establishments, 10-X header year 2012 for HQ.

The part worth flagging, because it looks like an inconsistency and a referee will ask: **this is the opposite of the `_l1` convention you use for committees.**

	cycle 2012 uses	why
committees (`cand_power_l1`)	**112th** -- the *sitting* Congress	The donor observes the committees in session. The incoming Congress's assignments are made *after* the election, so using them is look-ahead.
districts (`cd113`)	**113th** -- the *incoming* Congress	The candidate is running for a seat defined by the *new* map. Redistricting is complete and public before the election, so the donor knows it. Using the sitting map would place firms in boundaries that were never on the ballot.

Both are pre-election from the donor's standpoint; they just attach to different objects. The committee is a property of the Congress in session, the district is a property of the election being contested. I've written this into the build script's header so it doesn't get "corrected" later.

One edge case recorded there too: in redistricting years the map can still be in litigation early in the cycle. A donor giving in early 2011 may not have seen the final 2012 boundaries. It affects 2002, 2012 and 2022 at the margins, and it's the one case where the district convention has a genuine look-ahead sliver.

--- AUTHOR [2026-08-11 13:48:10] ----------
1. Then let's rename in_estab as in_estab_500. 2. How do you know "Geography under the rule -- in_hq | in_estab -- is 8.0% of donation rows"? 3. Regarding the inconsistency result you mentioned in the last run, I feel we should use _l1 committee membership assignment rather than _t committee membership assignment because _t committee membership assignment hasn't happened? So our current approach implicitly have an assumption that the district may not change for the next congress (it may change every ten years when the boundary is redrawn). If we use _t committee membership
  assignment in our analysis, we will implicitly asssume that the election results and assignments are very predictable, so both firms and politicians know that before the election. I feel the first approach has fewer assumptions?

--- AUTHOR [2026-08-11 13:49:03] ----------

      ↪  Political Donation Motive" && cat >> STATUS_MEMO.md <<'EOF'  ##

--- AGENT   [2026-08-11 13:53:09] ----------------------------------------
## 1. Renamed

`in_estab` -> `in_estab_500`, symmetric with `in_estab_250`. Panel regenerated, nothing else changed. Columns
are now:

`gvkey . cycle . cd_state . cd_district . cd_label . in_hq . hq_cd_n . hq_zip . estab_jobs . n_estab .
in_estab_500 . in_estab_250 . source`

## 2. Where the 8.0% comes from

For each of the 1,000 trial donation rows I test whether `(gvkey, cycle, cand_office_st,
cand_office_district)` appears in the panel with the flag set:

| | count / 1000 |
|---|---|
| `in_hq` | 35 (3.5%) |
| `in_estab_500` | 54 (5.4%) |
| **either -- the geography rule** | **80 (8.0%)** -- 9 of them both |
| `in_estab_250` | 90 (9.0%) |
| either, using 250 | 113 (11.3%) |
| *sample's own `hq_cd_match_cand`* | *39 (3.9%)* |

So it's literally 80 rows out of 1,000. Two caveats worth keeping attached to that number: it's the **trial
sample**, not the donation universe, so treat it as an order of magnitude. And the 3.5% against the sample's
own 3.9% is the reconstruction check -- two HQ measures from different sources (10-X + ZIP crosswalk here,
Compustat historical HQ there) landing in the same place.

## 3. Your reasoning is right, and better than mine

You've put it more precisely than I did. The two conventions don't just differ -- they differ in **how much
predictability each assumes**:

- **Committees at *t*** would need the donor to predict the election outcome *and* the subsequent committee
assignment. Two unknowns.
- **Committees at *t-1*** assume nothing. The donor observes the sitting Congress.
- **Districts at *t*** assume only that the boundaries are known -- and they are. Redistricting is completed
and published in law before the election, and happens once a decade, not every cycle.

So `_l1` committees plus incoming-Congress districts is the combination that assumes least. That's the
version to put in the paper; I've recorded it in the memo in your formulation.

**And I checked something that could have quietly broken this.** If your ZIP crosswalk used the *sitting* map
while my shapefiles used the incoming one, `in_hq` and `in_estab_500` would sit on different boundaries in
redistricting years. Test on cycle 2012, restricted to ZIPs where the crosswalk is unambiguous *and* the two
maps disagree (n=181): the crosswalk matches **cd113 55.8%** against **cd112 37.0%**, and the Arizona cases
settle it -- ZIP 85001 is AZ-07 in your crosswalk and under cd113, AZ-04 under cd112. **Your crosswalk
already uses the incoming map.** Both halves of the panel agree.

The one residual is the edge case already in the script header: in redistricting years the map can be in
litigation early in the cycle, so a donor giving in early 2011 may not have seen the final 2012 boundaries.
It touches 2002, 2012 and 2022 only.
```

```
## 4. Ubiquity -- agreed, closed

You're right, and I'd been treating a fact as a defect. A national chain genuinely does have 500+ employees
almost everywhere and genuinely does donate across many districts; suppressing that would be imposing an
assumption, not removing one. No screen. I've recorded it as closed so it doesn't get reopened as a "problem"
in a later session -- with the note that if the geography category later looks inflated for chains, the place
to look is the classification prompt, not the panel.

--- AUTHOR  [2026-08-11 14:11:42] ----------------------------------------
Regarding the inconsistent of redistricting years you found, here is my thought: for non-redistricting years,
_l1 committees plus incoming-Congress districts is the combination that assumes least. But for redistricting
years, many _l1 districts may change, so _l1 committees plus incoming-Congress districts may not be useful,
even if the combination still assumes least. On the other hand, _t committees plus incoming-Congress
districts may be more accurate because the boundary is real, even if it means we bear the costs of the
assumptions that candidates and firms can predict which candidates are going to win (I think it's the case
for many districts). So the idea is to use an approach with relatively lower costs. What do you think?

--- AGENT   [2026-08-11 14:12:17] ----------------------------------------
Let me test the premise your proposal rests on, because I think it may cut the other way.

      ↪  Political Donation Motive" && cat >> STATUS_MEMO.md <<'EOF'  ##

--- AGENT   [2026-08-11 14:16:07] ----------------------------------------
I'd keep one convention. Three reasons, and the third settles it.

## The two axes are independent

`cmte_l1` and `cand_power_l1` are properties of the **person**, not the district. Redistricting redraws
boundaries; it doesn't change which committees a sitting member serves on. Dave Camp chairs Ways and Means in
the 112th regardless of how Michigan's lines move.

So switching committee timing can't fix a boundary problem -- it's a different object. The concern you're
pointing at is real, but it lives entirely on the district side.

## The predictability premise runs the other way

From DIME, House candidates 2000-2022:

| | redistricting cycles | other cycles |
|---|---|---|
| incumbents winning re-election | 80.0% | 81.6% |
| candidates running for an **open seat** | **21.3%** | **16.2%** |

Redistricting years have *more* open seats and marginally *lower* incumbent survival -- retirements and
member-vs-member races spike when maps move. So "firms and candidates can predict who wins" is **less** true
in exactly the cycles where you'd be adopting it. That said, the gap is modest and 2012's open-seat share
(17.1%) is near average, so I'd call this supporting rather than decisive.

## The problem is empirically absent

The real redistricting concern is the case you're circling: a firm sat in an incumbent's **old** district,
gives to them, and the **new** district no longer contains the firm. Our rule would miss a tie that was
```

genuinely geographic.

I tested it directly -- current rule (new map, contested district) against old map plus the candidate's prior-cycle district:

cycle	incumbent rows	new-map rule	old map + old district	**recovered only by old**
2002	59	5	4	**0**
2012	91	6	5	**0**
2022	76	1	1	**0**

Zero of 226 rows would change. The reason is mechanical once you see it: a firm with 500+ employees somewhere doesn't move when a boundary does. If the incumbent still represents that area, the new district contains the firm too. Redistricting shifts *marginal* territory; large employers mostly sit in the core that stays put.

What I'd add to your reasoning

You framed this as choosing the lower-cost assumption, which is the right frame. The cost I don't think is priced in is that **a variable whose definition changes across cycles is very hard to defend**. A referee sees "committee timing switches in 2002, 2012, 2022" and immediately asks whether the results ride on the definitional break rather than on behaviour. And this panel already carries two time-varying properties -- Infogroup coverage and boundary resolution, both improving over time. A third would make them inseparable.

So: **`_l1` committees and incoming-Congress districts, in every cycle.** You keep the assumption-minimal combination, and you give up nothing measurable -- the thing it would have bought is zero rows.

--- AUTHOR [2026-08-11 20:39:03] ----------
We need to make one change to the data: Let's also add a >=100 no. of employees to the firm_cycle_district data because I may later even use 100 as the cutoff point.

--- AGENT [2026-08-11 20:39:17] ----------
Straightforward -- the floor has to drop to 100 so those rows exist in the file at all.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Code" && grep -n "JOBS_KEEP\|JOBS_MIN
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Code" && python - <<'PY' p="2.build_f
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Code" && python - <<'PY' p="2.build_f

--- AGENT [2026-08-11 20:51:03] ----------
That's exactly what I built -- `in_estab_100` is in the file. My verification script had a bug (rebuilding the lookup set inside the loop), so let me rerun it properly.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && PYTHONIOENCODING=utf-8 python - <<'PY' import pandas as pd, numpy as np,
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && cat >> STATUS_MEMO.md <<'EOF' ##

--- AGENT [2026-08-11 20:51:52] ----------
Done -- `in_estab_100` is in the panel, exactly as a filterable dummy.

The file's floor had to drop from 250 to 100 jobs for those rows to exist at all, so the panel grew from 325,597 to **588,479 rows** (parquet 3.5 MB, dta 46 MB). `in_estab_500` is unchanged and remains the rule.

flag	rows	districts/firm-cycle (median / p90)	trial-sample match	with HQ
`in_hq`	91,546	1 / 4	3.5%	--
`in_estab_500` (rule)	120,288	2 / 11	5.4%	**8.0%**
`in_estab_250`	250,307	2 / 17	9.0%	11.3%
`in_estab_100`	520,876	3 / 30	13.9%	16.0%

Columns are now `gvkey . cycle . cd_state . cd_district . cd_label . in_hq . hq_cd_n . hq_zip . estab_jobs . n_estab . in_estab_500 . in_estab_250 . in_estab_100 . source`.

One thing to watch when you filter. `source` still describes each row under the *rule* -- so a district clearing 100 or 250 but not 500, and not an HQ district, reads `estab_below_rule` (387,419 rows). That's deliberate, so the 500 rule can't be misread, but it means you should filter on the flag (`in_estab_100 == 1`) rather than on `source` when you want a looser cutoff.

And for when you come to use it: 100 puts geography at **16.0%** of donation rows -- four times the current HQ-only measure, twice the rule -- with a p90 of 30 districts per firm-cycle. At that point the category is closer to "the firm operates here" than "this district is where the firm is." The evidence I ran earlier pointed the other way (discrimination improved going from 250 to 500), so I'd treat 100 as a sensitivity bound rather than a candidate rule unless something new argues for it. Having the dummy there costs nothing either way.

--- AUTHOR [2026-08-11 21:13:04] ----------
So it means with in_estab_100 cutoff and HQ district condition, we have 16.0% geographically motivated donations out of the 1000 observations we draw. Is this understanding correct?

--- AGENT [2026-08-11 21:13:27] ----------
Not quite, and the gap matters. Let me show you exactly what the 16.0% is and isn't -- including what adopting it would do to your other categories.

[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && ↪ PYTHONIOENCODING=utf-8 python - <<'PY' import pandas as pd, numpy as np

[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && cat >> STATUS_MEMO.md <<'EOF' ##

--- AGENT [2026-08-11 21:14:46] ----------
Not quite -- and the gap is the thing your paper is about.

16.0% is the share where a geographic *condition* is satisfied: the firm's HQ is in the candidate's district, or its establishments there employ >=100. That's a **necessary** condition for a geography motive, not a sufficient one. Whether presence is the *reason* for the gift is precisely what the classifier is supposed to decide.

The proof is inside the 160 rows. Here's what they're labelled today, under v2's HQ-only geography:

condition	rows	already `geography`	would be reclassified	taken from `committee`
HQ or >=500	80 (8.0%)	38	42	21 (4% of committee)
HQ or >=250	113 (11.3%)	38	75	36 (7% of committee)
HQ or >=100	160 (16.0%)	38	122	**59 (11% of committee)**

59 of the 160 are currently `committee`. For those rows both facts are true at once -- the firm employs people in the district *and* the candidate sits on a committee with jurisdiction over its business. The condition can't say which drove the donation. What would move them into `geography` is the priority rule (geography ranks first), which is a convention you adopted, not something the data established.

So the accurate sentence is:

> 16.0% of donations satisfy the geographic condition at the 100-employee cutoff. Under the v1/v2 priority rule that would become the *size of the geography category*, absorbing 11% of what is currently committee.

Why I'd flag this rather than let it pass

This is the exact conflation your `CLAUDE.md` positions the paper against -- proxies that "conflate motive with opportunity: a firm headquartered in a chairman's district loads on three proxies at once." Widening the geographic condition manufactures more of those multi-loading rows and then resolves them by fiat. At 100 employees you'd be doing it to 122 donations.

Two things follow:

1. **Read 8/11/16% as upper bounds on geography's share, never as estimates of it.** The number tells you how many donations *could* be geographic, which is the useful thing for sizing the category -- not how many *are*.

2. **The classifier needs to actually adjudicate.** `_runlog.md` already records that geography "tracks the district-match rate exactly -- the category reports what the HQ mapping says and adds nothing." The model echoed the indicator rather than judging it. Handing it a wider indicator makes that worse, not better. If the establishment measure enters the taxonomy, the prompt should put presence and jurisdiction side by side as competing explanations and require a stated reason for choosing, instead of letting the priority order decide silently.

That's also the honest answer to why 500 looked better than 250 earlier: the tighter condition produces fewer rows where two motives both plausibly apply.

--- AGENT [2026-08-11 21:21:41] ----------

That was the slow first version of the verification script finishing in the background. Its numbers match the corrected run exactly -- 588,479 rows, 12,695 gvkeys, and 3.5% / 8.0% / 11.3% / 16.0% across the four conditions. Nothing to revise.

State of things:

- **`Data\firm_cycle_district_2000_2024.{parquet,dta}`** -- 588,479 firm-cycle-district rows, built by `Code\2.build_firm_district_panel.py`, with `in_hq`, `in_estab_500` (the rule), `in_estab_250`, `in_estab_100`, plus `estab_jobs` and `n_estab` so any cutoff is a filter rather than a rebuild.
- **`1.Common Dataset\Politics\1.CD Boundary Shapefiles\`** and the **Infogroup gvkey establishment panel** are both registered shared assets with their own READMEs and rebuild scripts.
- Everything is committed, and `STATUS_MEMO.md` carries the decisions with their evidence.

The open item I'd flag for whenever you pick this up next: the geography category can't just inherit the priority rule if the establishment measure enters. On the current v2 labels, 59 of the 160 rows meeting the >=100 condition are classified `committee`, and the ordering would silently reassign them. That's a prompt-design decision -- presenting presence and jurisdiction as competing explanations and requiring a stated reason -- rather than a data one, so the panel is ready either way.

--- AUTHOR [2026-08-11 21:28:30] ----------

We also need to make changes to taxonomy_decisions and prompts regarding Ways and Means committees and Appropriations committees.
I want to remove the following restrictions when classifying donation motives.
Ways and Means -- a distinctive stake, not the tax code in general. It holds taxation, tariffs, Social Security and Medicare. Every corporation pays tax, so a general corporate-tax interest does **not** qualify; crediting it on that basis would make the category meaningless.

O2 -- No rule for which firms care about Appropriations. Membership is fully covered in Stewart & Woon (895 member-Congress rows, 190 members). What is missing is the firm side: the GICS4 crosswalk has 11 committees and no Appropriations link, because exposure is firm-specific (federal contractors, funded research, infrastructure) rather than industry-generic. Round-1 approach: let the model judge and log its reasoning.

Because these two committees don't oversee specific industries, we don't need to link specific industries to them. The idea is that if a firm donates to a member of those two committees, we can classify those donations under "committee" motive category. I want to update or create new versions of classification_prompt and taxonomy_decisions md files to reflect the changes.

--- AGENT [2026-08-11 21:28:41] ----------

Let me read the current prompt and see exactly what's being relaxed, then size the change before writing it.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance" && grep -n -i -B3 -A12 "way
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && PYTHONIOENCODING=utf-8 python - <<'PY' import pandas as pd, numpy as np

--- AGENT [2026-08-11 21:29:24] ----------

Correction to my own arithmetic before I write it: geography outranks committee in the priority order, so those 8 rows shouldn't move.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects" && PYTHONIOENCODING=utf-8 python - <<'PY' import pandas as pd d=pd.read_csv

--- AGENT [2026-08-11 21:29:48] ----------

Correct impact: **70 rows move**, committee 524 -> 594. Now writing v3.

      ↪  Political Donation Motive" && sed -n '186,200p' Guidance/taxono
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && cat >> STATUS_MEMO.md <<'EOF'  ##

--- AGENT   [2026-08-11 21:31:50] ----------------------------------------
Done -- taxonomy **v3** and **`classification_prompt_v3.md`**.

## What changed

`classification_prompt_v3.md` is a copy of v2 with only ?2 altered. The seven categories and the priority
order are untouched, so the two files diff cleanly.

| | v2 | v3 |
|---|---|---|
| Ways and Means | credited only for a distinctive stake -- excise, tariffs, Medicare payment, targeted
credits | **membership qualifies** |
| Appropriations | credited only where the firm sells into a federal programme | **membership qualifies** |
| every other committee | jurisdictional link to *this* firm | unchanged |

I wrote the reasoning into the prompt rather than just the rule, since the model needs to know *why* the
exception exists or it'll try to apply the old test anyway: these two committees have no sectoral
jurisdiction to test against, so a jurisdiction test has nothing to bite on. The prompt also says a specific
stake may still be named in `motive_detail` if visible, but its absence is never grounds to reject the
category.

`taxonomy_decisions.md` gains a v3 section with v1 and v2 left intact, per that file's append-only rule.
**Open item O2 is closed** -- the rule is membership, so the missing GICS4-Appropriations link is no longer a
gap to fill.

## What it does to the trial sample

234 rows (23.4%) have a candidate on one or both committees -- 143 Ways and Means, 91 Appropriations. Of
those, 156 were already `committee`, and **8 are `geography`, which outranks committee and so keeps them**.
That last point cost me a correction: my first pass moved those 8 and overstated the change as 78 rows.

**70 rows move:**

| | v2 | v3 |
|---|---|---|
| committee | 524 (52.4%) | **594 (59.4%)** |
| incumbent_access | 292 (29.2%) | **234 (23.4%)** |
| incumbent_powerful | 54 | 44 |
| social_ties | 6 | 4 |
| geography | 39 | 39 |
| contestant_investment | 85 | 85 |

These are v2's labels re-sorted under the v3 rule, not a fresh run -- same caveat as the v2 derivation, since
a model told up front that membership suffices may allocate borderline cases differently.

## One consequence I've recorded rather than argued about

The rule is right on its own terms -- a donation to a Ways and Means member *is* a committee donation, and
rejecting it because the committee's remit is broad was the wrong test. But it makes the measure more
mechanical: **234 of the 896 committee-holding rows (26%) now need no judgement at all.** Only 662 still turn
on the firm-to-committee jurisdiction call.

That call is exactly what the redundancy gate identified as the measure's engine -- 33% of v1 labels weren't
recoverable from the five mechanical indicators, and the disagreement sat almost entirely there. So **the
gate should be re-run after the next classification round.** If non-recoverability drops materially below
33%, the taxonomy has traded interpretive validity for coverage, and that's worth knowing before a referee
finds it. It's in the memo and the v3 section so the next session picks it up.

--- AUTHOR  [2026-08-11 23:21:48] ----------------------------------------
1. I feel our approach treats the Ways and Means Committee and the Appropriations Committee as not having
```

overseen industries, right? If so, we should do the following: if a candidate sits on multiple committees, we should first consider committees that have corresponding industries to oversee.
2. I think our priority order is still geography -> committee -> social ties -> incumbent/contestant. And we also have a secondary motive to be assigned as well, right? One question I have here: since we include the Ways and Means Committee and the Appropriations Committee, should we adjust the priority order and make "social ties" have higher priority over "committee"?

--- AGENT [2026-08-11 23:22:20] ----------
Both questions bear on the same thing, and I think there's a sharper answer than the one you're proposing. Let me get the numbers first.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && PYTHONIOENCODING=utf-8 python - <
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && PYTHONIOENCODING=utf-8 python - <

--- AGENT [2026-08-11 23:23:47] ----------
Numbers in hand. On Q1 you're right, and on Q2 there's a sharper version of your instinct.

Q1 -- yes. 108 of the 234 W&M/Appropriations rows (46%) also sit on another committee. And of the 70 rows that *move* under v3, 27 also hold a sectoral committee -- but those were judged to have no jurisdiction over the firm, so the broad-committee membership is genuinely what credits them. Ordering sectoral first is the right rule and changes what `motive_detail` records in the 108 overlap cases.

Q2 -- your instinct is right, but "committee got bigger" isn't the strongest reason. The real one is that **v3 broke the taxonomy's own stated principle.** The v1 priority order was justified as *"firm-relational categories before candidate-only ones."* Under v3, a Ways and Means credit tests **no firm-specific link at all** -- it's candidate-only. So v3 placed a candidate-only condition above a firm-relational one.

That reframes the fix. Committee is now two different things doing different work:

basis	firm-specific?	judgement?	rows
sectoral jurisdiction over *this* firm	yes	yes	662 of 896 committee-holders
W&M / Appropriations membership	**no**	no	234

Which suggests they belong at different priority levels rather than sharing one slot:

```
1  geography                            firm-relational
2  committee -- sectoral jurisdiction    firm-relational
3  social ties                          firm-relational
4  committee -- W&M / Appropriations     candidate-only
5  incumbent_powerful  6 access  7 contestant
8  others
```

This restores the stated principle, and it implements your Q1 automatically -- sectoral committees are considered before the broad ones by construction.
[action] AskUserQuestion:

--- AGENT [2026-08-11 23:26:32] ----------
What would you like to clarify? Some things I can expand on if useful:

On the numbers. The trial-sample counts I quoted for social ties are soft. My reconstruction from `Data/social_tie_shortlist_*.csv` finds 8 donation rows with a qualifying tie (+/-5-year graduation overlap), while the actual v2 run labelled 6 rows `social_ties`. The two don't line up exactly -- the run's promotions (Tenet->Altmire, Salesforce->Lieu) came through the government-affairs channel and may sit outside my reconstruction. So "social_ties 4->6" under the split is an estimate, not a count. The direction is solid; the magnitude is small either way, because the category is tiny.

On what the split would cost. It makes the priority order seven slots instead of six and requires the classifier to record *why* a committee credit fired -- which I'd want anyway as a `committee_basis` field, so the redundancy gate can be re-run on the judgement-based subset alone. That's the part that protects against committee becoming a lookup table.

On what I may be assuming that you'd read differently. I treated a W&M/Appropriations credit as "candidate-only" because no firm-specific test is applied. You could argue the opposite: every corporation has a tax and appropriations interest, so the link *is* firm-relational, just universal rather than distinctive. If that's your reading, the case for reordering weakens considerably and "leave it as is" becomes defensible.

Or something else entirely -- whether social ties belongs as a category at all given it's 0.4-1% of the sample, whether the secondary-motive field (`motive_2nd`) should carry the runner-up rather than reordering the primary, or how any of this interacts with the fresh v3 run that hasn't been done yet.

Which of these, or something I haven't listed?

--- AUTHOR [2026-08-11 23:32:22] ----------
1. I think committee -- sectoral jurisdiction should only capture the committee have jurisdiction over the firm. Then we consider the Ways and Means Committee and the Appropriations Committee. If a candidate sits on other committee, I don't think we should classify donations to them as "committee" motive? Also would it be better to have two split variables such as "committee -- sectoral" and "committee -- W&M / Appropriations"?
2. If we do what I wrote in 1, do we still need to re-prioritize the ordering? Also I agree the secondary-motive field (motive_2nd) should carry the runner-up rather than reordering the primary, so we don't have no issues on this.

--- AGENT [2026-08-11 23:32:48] ----------
Let me check one thing that determines the answer to your second question -- whether the two bases can both fire on the same row.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && PYTHONIOENCODING=utf-8 python - <

--- AGENT [2026-08-11 23:33:25] ----------
Confirmed and decisive: **the two bases are not mutually exclusive.** Seven v2 rows credit a sectoral committee while the candidate also sits on Ways and Means (Navient -> Budget chair *and* W&M; UST -> Agriculture *and* W&M). A single categorical would force a false choice. And the true count is higher than 7 -- v2 recorded only the first committee it credited, so it never looked further.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance" && grep -n "## 5" classific
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance" && python - <<'PY' p="class
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance" && python - <<'PY' p="taxon

--- AGENT [2026-08-11 23:34:45] ----------
Both settled, and your framing in (1) resolved (2).

1. Committee logic -- implemented as you describe

The prompt now works through committees in order:

1. **A committee with jurisdiction over this firm** -> credit it, name it in `motive_detail`, set `cmte_sectoral`
2. **Ways and Means or Appropriations** -> membership alone qualifies, set `cmte_broad`
3. **Any other committee with no jurisdiction** -> **not** category 2; the row falls through

That third rule was already how v1 and v2 worked, but it wasn't stated as a rule -- it's explicit now.

And yes, two split variables is the better design -- because the two bases are not mutually exclusive. Seven v2 rows already credit a sectoral committee while the candidate also sits on Ways and Means: Navient (Budget chair *and* W&M), UST (Agriculture *and* W&M), RRI Energy (Natural Resources *and* W&M). A single categorical field would force a choice between two facts that are both true. Two dummies record both.

The true count is higher than seven, incidentally -- v2 stopped at the first committee it credited and never looked further. The v3 prompt now tells the model to check every committee in `cmte_l1` before writing the row.

2. No, you don't need to reprioritise -- and the dummies are why

This is the part I'd underweighted when I proposed the split ordering. My concern was that a candidate-only condition (broad-committee membership) now outranks a firm-relational one (a social tie), contradicting v1's stated rationale. That concern was about **information being destroyed** -- the tie disappearing into a `committee` label.

But with `cmte_sectoral`, `cmte_broad` and `motive_2nd` all recorded, nothing is destroyed. Any alternative ordering becomes reconstructible after the fact:

```
social ties above broad-committee credits:
    motive=="committee" & cmte_sectoral==0 & motive_2nd=="social_ties"  ->  social_ties
```

```

That's **strictly better than choosing an order now**, because it turns the priority order into a robustness check rather than a baked-in assumption. You can report the main taxonomy and show the alternative in a footnote, without re-running the model. My proposed seven-slot ordering would have locked in one answer and made the others unrecoverable.

**One condition, and it needs watching.** This only works if `motive_2nd` actually carries an outranked tie. In v2 it was `others` on 72% of `incumbent_access` rows -- the field has not been reliable. So the v3 prompt now *requires* it: if a social tie exists but is outranked, `motive_2nd` must be `social_ties`. Worth making that an explicit QC check on the next run, since it's a new requirement rather than existing behaviour.

Files: `Guidance/classification_prompt_v3.md` and the v3 section of `Guidance/taxonomy_decisions.md`, both committed. v1 and v2 remain untouched.

--- AUTHOR  [2026-08-11 23:35:42] ----------------------------------------
Yeah, so the ordering I have is something like geography -> committee-sectoral -> committee- W&M / Appropriations -> social ties -> incumbent/contestant. This is the questioN I wanted to ask.

--- AGENT   [2026-08-11 23:35:59] ----------------------------------------
That ordering is **operationally identical to what v3 already does** -- let me show you why, because it's worth being sure rather than taking my word.

--- AGENT   [2026-08-11 23:37:24] ----------------------------------------
Adopted -- and worth being explicit about why it's safe:

## Your ordering produces exactly the labels v3 already produces

```
yours: geography -> committee-sectoral -> committee-W&M/Approp -> social ties -> incumbent/contestant
v3 was: geography -> committee ------------------------------> social ties -> incumbent/contestant
```

Splitting a category into consecutive slots can only change an outcome if something ranks **between** them. Here both committee slots sit above social ties, so for any row: if either committee basis holds, both forms assign `committee`; if neither holds, both fall through to social ties. Identical, by the resolution rule itself.

(That "between" case is exactly the variant I floated earlier -- social ties *between* sectoral and broad -- and you've declined it. Which is the one substantive fork here, and it's now closed.)

So this is a documentation change. But a good one: the five-slot form puts the sectoral-first rule **into the priority order**, where a reader will see it, instead of leaving it buried in ?2. It's now the stated order in both `classification_prompt_v3.md` and the v3 taxonomy section.

## One thing I corrected while I was in there

The prompt still carried v1's justification -- *"firm-relational categories come before candidate-only ones."* That sentence no longer describes the order: a Ways and Means credit tests no firm-specific link, yet outranks a social tie. Leaving a false rationale in a prompt is worse than leaving none, since the model reads it and may generalise from it.

It now says plainly that the order is your decision, and that it's **recoverable rather than binding** -- `cmte_sectoral`, `cmte_broad` and `motive_2nd` between them record enough to re-derive any alternative ordering after the fact. That's also why the prompt now *requires* `motive_2nd` to carry an outranked social tie: it's the only thing making the order recoverable, and in v2 that field was unreliable (`others` on 72% of `incumbent_access` rows).

## Where v3 stands
```

- `Guidance/classification_prompt_v3.md` -- v2 with ?2 rewritten, the five-slot priority, and two new output columns
- `Guidance/taxonomy_decisions.md` -- v3 section appended; v1 and v2 untouched; open item O2 closed
- Not yet run. The trial-sample figures I've quoted (committee 524->594, `incumbent_access` 292->234) are v2's labels re-sorted under the v3 rule, not a fresh classification.

When you do run it, the two checks I'd put in QC: that `motive_2nd` actually carries outranked ties, and the redundancy gate re-run on the `cmte_sectoral == 1` subset alone -- that's the part of committee that still turns on judgement, and it's the number that tells you whether the measure still has an engine.

--- AUTHOR [2026-08-11 23:39:53] ----------
So if a candidate sits on both committee-sectoral and committee- W&M / Appropriations and the donation is not geography motivated, the motive_2nd would be "committee- W&M / Appropriations", right? We can use better variable values for what I mean, but this is my idea. The committee-sectoral is the one that has jurisdiction over firm's industry, rather than ant sectoral committee. What do you think? Ways and Means credit may carry firm-specific link, which is just less direct than a sectoral committee.

--- AGENT [2026-08-11 23:40:27] ----------
Three separate things there, and you're right on the third -- my language was imprecise. Let me take them in order.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive/Guidance" && grep -c "cmte_sectoral"

--- AGENT [2026-08-11 23:41:45] ----------
Taking your three points in reverse order, because the third one changes the other two.

You're right, and "candidate-only" was my error

A Ways and Means credit **does** rest on a firm-specific link -- every corporation has a tax, tariff or appropriations interest. What it lacks isn't the link, it's **differentiation**: the link is identical for every donor, so it says nothing about why *this* firm gave to *this* candidate. A jurisdiction match is the same kind of link, made specific.

That correction actually **rescues the priority rationale instead of abandoning it**. The order isn't "firm-relational before candidate-only" (which was false), it's *the more discriminating form of the link outranks the less discriminating one*. Which is a better justification than the original, and it puts geography -> jurisdiction -> W&M -> ties on one coherent scale.

It also strengthens the v3 rule itself. The "money committee" regularity -- Ways and Means and Appropriations members raising far more than other members -- is exactly what a real-but-undifferentiated link predicts. Under v2's stricter test you'd have been rejecting the best-documented pattern in the literature. Both files now say this.

`cmte_sectoral` -> `cmte_juris`

Your warning was the right one: "sectoral" invites "any industry-oriented committee." The test is jurisdiction over *this firm's* business -- Agriculture is an industry committee, but for a software firm it's slot 2 only if the firm's business actually falls under it. The prompt now says that in those words, and the priority slot reads **"Committee -- jurisdiction over this firm"** rather than "sectoral." Renamed everywhere in the v3 files; nothing has been run under the old name.

On `motive_2nd` -- I'd not do it that way

Your goal is right: record that both bases applied. But `cmte_juris` and `cmte_broad` already do it, and putting `committee` in `motive_2nd` costs two things:

1. **It mixes category with basis.** `motive_2nd = committee` when `motive = committee` isn't a runner-up motive, it's a footnote about the same one.
2. **It crowds out the social tie** -- and that's load-bearing. `motive_2nd` carrying an outranked tie is the only thing that makes your priority ordering re-derivable after the fact. A row with jurisdiction + W&M + a tie has one `motive_2nd` slot; if the broad committee takes it, the tie is gone and the alternative ordering

can't be reconstructed.

So the prompt now states `motive_2nd` is the runner-up **category**, never a second reading of the same one, and stays free for the next genuinely different motive. When both committee bases fire you get `motive = committee`, `motive_detail = the jurisdiction committee`, `cmte_juris = 1`, `cmte_broad = 1` -- which is strictly more information than `motive_2nd` could hold, and in queryable form.

If you'd still rather see it in `motive_2nd`, the clean version is a separate `cmte_second` field rather than overloading the runner-up -- say the word and I'll add it.

--- AUTHOR [2026-08-11 23:47:31] ----------
1.To make "cmte_sectoral -> cmte_juris" more explict, let's use "cmte_sectoral -> cmte_sector_juris". 2. So you think a better version of motive_2nd should to include the next categorical value, and because "cmte_sector_juris" and "cmte_broad" are two values of cmte_broad, we should be better to use a separate category?
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && python - <<'PY' for p in [r"Guida

--- AGENT [2026-08-11 23:48:01] ----------
Two wording residues from the successive edits -- fixing so the prompt doesn't contradict itself.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance" && python - <<'PY' p="class

--- AGENT [2026-08-11 23:48:39] ----------
1. Renamed

`cmte_sector_juris` and `cmte_broad`, throughout the v3 files. v1 and v2 untouched, and nothing has been run under any earlier name.

While renaming I found two contradictions the successive edits had left in the prompt, both now fixed: it told the model "do not look for a firm-specific link" while the rationale said the link exists but is undifferentiated. It now gives the operational instruction (don't ask for a *distinctive* stake) and the reason (the link is the same for every firm, which is what makes it untestable) without the two fighting.

2. Yes to your first half -- with one correction on the second

`motive_2nd` = the next different category. Confirmed.

But `cmte_sector_juris` and `cmte_broad` are not two values of one variable -- they're two independent dummies, and that distinction is the whole point. Both can be 1 on the same row: 7 confirmed cases in v2 (Navient on Budget *and* Ways and Means; UST on Agriculture *and* Ways and Means), and certainly more, since v2 stopped at the first committee it credited and never looked further.

If they were two values of a single field you'd have to choose one, and you'd lose the fact that both applied -- which is exactly the information you wanted recorded. Two dummies keep both.

So the final scheme:

field	holds
`motive`	the category, one of seven
`motive_detail`	the specific thing -- for `committee`, the jurisdiction committee if one applies, else W&M / Appropriations
`motive_2nd`	runner-up **category**, always different from `motive`; carries an outranked social tie
`cmte_sector_juris`	1 if a committee has jurisdiction over this firm's business
`cmte_broad`	1 if the candidate sits on Ways and Means or Appropriations

One design point worth flagging, since it's what makes the dummies pay for themselves: they're filled on **every row where the candidate holds a committee seat**, whatever `motive` ends up being -- including rows classified `geography` or `incumbent_access`. That's what lets you re-run the redundancy gate on the `cmte_sector_juris == 1` subset alone. Which is the check that tells you whether committee still has an engine after v3 made 26% of it mechanical, and it only works if the flags are recorded independently of the label.

--- AUTHOR [2026-08-11 23:51:29] ----------
Obviously the classification rule is the most crucial for this project, so we need to think about it more thoroughly. Here is a question/comment from my coauthor: Whether that is accurate or not depends on the confidence around the secondary motive. If the bar is the same for primary and secondary then that's fine and we can just create a blanket "multiple reasons" variable to capture those. If the secondary motive is allowed to have lower confidence, then this is not the same thing as what I was describing.

```
My point is basically that we shouldn't have a priority ordering.  All else equal, a same-state or
same-district candidate who chairs an important committee is probably more valuable than a chair from another
state.

The more I think about this the more I feel we should drop the incumbent flag and just have the three reasons
and an "other" category, where none of the reasons are ranked and a candidate can check more than one box.
. What do you think?

--- AGENT   [2026-08-11 23:52:15] ----------------------------------------
This is the most consequential question in the session, and I think your coauthor is right. Let me put
numbers behind that rather than just agreeing.

      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && cat >> STATUS_MEMO.md <<'EOF'  ##

--- AGENT   [2026-08-11 23:54:31] ----------------------------------------
I think your coauthor is right on all three points -- and two of them are supported by evidence this session
already produced.

## The confidence objection is not hypothetical

The prompt caps `social_ties` at confidence 2. So the secondary motive is **already** held to a different bar
than the primary, exactly the case your coauthor says would break the equivalence. Today, "primary +
secondary" genuinely isn't "multiple reasons."

The fix is what they're implying: one 1-5 scale per flag, no caps. Weak evidence for a tie shows up as low
confidence *on that flag* rather than as a ceiling on the category. The blanket "multiple reasons" variable
is then just the row sum of the flags.

## The priority rule decides a large share of geography -- and is about to get worse

| geography measure | geography rows | **also satisfy committee** | rows with >1 reason |
|---|---|---|---|
| HQ only (current, 3.9%) | 39 | **21%** | 14 (1.4%) |
| HQ or estab >=500 (8.0%) | 80 | **40%** | 38 (3.8%) |
| HQ or estab >=100 (16.0%) | 160 | **48%** | 81 (8.1%) |

Under HQ-only the rule hid almost nothing -- which is why this hasn't bitten yet. Under the establishment
panel we just built, it silently resolves **40% of the geography category**.

Your coauthor's example is literally in the data: same state + committee + powerful is 17 rows, which v2
split 12 `committee` / 4 `incumbent_powerful` / 1 `geography` -- entirely on the ordering, not on anything
about the donations.

## Dropping the incumbent flag is the most defensible part

`incumbent_access` is **283 of 292 rows at confidence exactly 3**, with `motive_2nd = others` for 72%. It's
the negative image of the committee judgement, not a motive.

And dropping it costs nothing, because incumbency is already the field `cand_ici`. Your coauthor is applying
the taxonomy's *own* principle more consistently than the taxonomy does -- v1 made power a field on the
grounds it's "an intensity dimension of access rather than a distinct motive." That reasoning applies to
incumbency word for word.

## What it costs, so it's priced

- **"Other" becomes 31-37%.** Large, but that mass is currently hidden inside `incumbent_access` at 29.2%
saying nothing. "None of the three reasons is established" is a *finding* about corporate PAC giving, not a
classifier failure.
- **The research question shifts** from "the primary motive" to "which motives apply." `CLAUDE.md`'s R
survives intact; the phrase "primary motive" in it doesn't. Your call.
- **Box-checking inflation is the real implementation risk.** Unranked multi-select invites the model to tick
```

```
everything. Each flag needs its own evidence requirement and its own confidence, which makes each row more
work.

## One synthesis worth putting to your coauthor

They object to a **global** priority rule. That's compatible with asking the model, per row, *which reason
was decisive and why* -- a per-observation judgement rather than a taxonomy-level convention. It keeps a
primary for the outcome regressions while dropping the fiat.

It's also where an LLM should beat a mechanical rule: a rule can't say which of three satisfied conditions
mattered; a reader of the record might. And it's **testable** -- if the "decisive" field turns out as
uninformative as `motive_2nd` did, that's a finding about what this method can deliver, which is worth
reporting either way.

## Timing favours doing it now

**Nothing has been run under v3.** Switching costs no redone classification -- only the prompt and taxonomy
files, which are cheap. Doing it after a run would be expensive.

Four decisions, if you want to take them back to your coauthor: adopt multi-label as v4; keep a per-row
"decisive reason" field or not; drop all three incumbent/contestant categories (retaining `cand_ici` and
`cand_power_l1` as fields); and which geography measure feeds the flag.

--- AUTHOR  [2026-08-12 00:01:08] ----------------------------------------
So what will the the updated categories and rules we want to have? Should we have multiple columns (one
column for one motive) and tick the column as long as one donation meets the criterion of that column?

--- AGENT   [2026-08-12 00:01:38] ----------------------------------------
Here's the concrete design. Let me put it in a file you can send your coauthor rather than leaving it in
chat, and keep v3 intact until it's agreed.
      [action] Write: G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI -
      ↪  Political Donation Motive\Guidance\taxonomy_v4_proposal.md
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -

--- AGENT   [2026-08-12 00:03:16] ----------------------------------------
Understood -- discussion document, not a decision. That's how it's labelled, and v3 stays of record.

Your finer-"other" idea unlocks something specific that I should flag, because it dissolves an objection that
has blocked a category twice.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/Guidance" && python - <<'PY' p="taxon

--- AGENT   [2026-08-12 00:04:14] ----------------------------------------
Understood on both counts -- it's a discussion document for you to react to, and v3 stays of record.

## Answering your question directly

**Yes: one column per reason, ticked independently.** Four unranked flags, any number of which may fire:

`m_geography` . `m_committee` . `m_social_tie` . `m_other`

with `n_reasons` as their sum (your coauthor's "multiple reasons" variable, free) and `m_none` where nothing
is established.

Two things in the draft go beyond restating the idea, and they're the parts I'd most want your reaction to:

**`m_other` is a positive claim, not the residual.** It means "a different reason was found, here it is."
Rows where nothing is established have all four flags at 0. v1-v3 conflated these -- the `others` category
explicitly mixed "a different motive" with "not enough information," which are opposite epistemic states.

**Merge the mechanical flags; ask the model only for the judged ones.** `m_geography` now comes entirely from
the district panel, and `cmte_broad` is a string match on `cmte_l1`. Asking the model to tick those invites
an echo -- `_runlog.md` already records that in v1 geography "tracks the district-match rate exactly ... and
adds nothing." That leaves three genuine judgements: `cmte_sector_juris`, `m_social_tie`, `m_other`. It also
makes the redundancy gate honest by construction, since under v3 the mechanical flags would sit *inside* the
thing being tested.

## Your finer-`other` point unlocks something specific
```

Implemented as `other_type` (controlled vocabulary, multi-valued) + `detail_other` (free text, always required) + `conf_other`, seeded from reasons the record shows have nowhere to go -- `leadership_access` (which `_runlog.md` explicitly flags as homeless), `ideology`, `state_delegation`, `bill_sponsorship`, `trade_association`, `relationship_maintenance`, `constituent_executive`. Open list: a type that recurs gets promoted to its own flag next version, one that never fires gets dropped. The taxonomy learns from a round instead of being fixed in advance.

And here's the thing worth putting to your coauthor. Both v1 and v2 defer party/ideology for one stated reason:

> "it overlaps category 3 across most of the sample rather than at the margin, so a priority rule would *set* its size by convention instead of differentiating it."

That objection exists only because there is a priority rule. Under unranked flags, an overlap is just recorded -- nothing has to be resolved, so no convention sets the category's size. The test v2 proposed for ideology (classify one batch with and without it, see which category shrinks) becomes unnecessary, because the co-occurrence is observed directly.

So a category the project has twice wanted and twice deferred becomes available at no cost. That's a real argument *for* the redesign, independent of the ones your coauthor made.

The caveat from 2026-08-10 still binds: *candidate* party separates nothing inside `incumbent_access` (p=0.58 on size, p=0.65 on persistence). Ideology has to enter as firm-candidate **alignment**, which needs the firm's partisan concentration at t-1 -- still unbuilt, and the one thing on this list that costs real work.

The full document is `Guidance/taxonomy_v4_proposal.md` if you want to send it across.

--- AUTHOR [2026-08-12 00:22:30] ----------
1. What does "m_" stand for? 2. Do we need to further have cmte_sector_juris and cmte_W&M / Appropriations (or a third cmte_other)? 3. Would it be better to have a other_incumbent and contestant column as well? My idea is we can get sufficient information when assigning the classifications, and we can always aggreate or drop some columns later when we feel doing so.

--- AGENT [2026-08-12 00:22:59] ----------
Good questions -- and (3) has an answer I think you'll like better than adding columns.

[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && cat >> STATUS_MEMO.md <<'EOF' ##

--- AGENT [2026-08-12 00:24:32] ----------
1. `m_` = motive -- now written out

Same principle that turned `cmte_juris` into `cmte_sector_juris`: a name that has to be looked up gets misread eventually. So `motive_geography`, `motive_committee`, `motive_social_tie`, `motive_other`, `motive_none`.

And `cmte_broad` -> **`cmte_wm_approp`**, which says what it *is* rather than how wide it is.

2. Two bases, not three

`cmte_sector_juris` and `cmte_wm_approp`. A third `cmte_other` -- "sits on committees, none qualifying" -- is **derivable** from `n_cmte_l1`, which is already merged into the sample:

```
n_cmte_l1 > 0 & cmte_sector_juris == 0 & cmte_wm_approp == 0
```

3. On incumbent/contestant columns -- your principle is right, but it stops short of these

Collecting finely and aggregating later is exactly right, and it's why `other_type` exists. But it applies to things **not already in the data**. Here's the discipline I'd propose: *ask the model only for what isn't already known.* Every asked column costs attention on every row and adds a failure mode.

considered	why not ask	derive instead

`cmte_other`	`n_cmte_l1` is merged	`n_cmte_l1 > 0 & both bases 0`
`motive_incumbent`	`cand_ici` is merged -- **and the claim was already tested and came back empty**	`motive_none == 1 & cand_ici == "I"`
`motive_contestant`	`cand_ici` again	`motive_none == 1 & cand_ici != "I"`

That middle row is the important one. v2 *did* ask this question, as `incumbent_access` -- and got 283 of 292 rows at confidence exactly 3, with `motive_2nd = others` on 72%. The model could not separate "gave because incumbent" from "found no other reason." Asking again in flag form would reproduce the same emptiness at the same cost.

The content survives twice over, which is why nothing is lost:

- as **merged facts** -- `cand_ici`, `cand_power_l1`, `cand_ever_power_l1`, `n_cmte_l1`
- as **positive claims that must be evidenced** -- `other_type = leadership_access` is what `incumbent_powerful` was reaching for, and `other_type = relationship_maintenance` is the defensible half of `incumbent_access`

The difference is that under v4 those have to be argued in `detail_other` rather than assigned by elimination. v2's `incumbent_access` was 29.2% of the sample assigned *because nothing else applied*. Under v4 the same rows read `motive_none = 1, cand_ici = "I"` -- which says the identical thing, honestly, and costs no column.

So you keep your full cross-tabulation of incumbency against motives whenever you want it; it just comes from a merge rather than from asking the model a question it demonstrably can't answer.

--- AUTHOR [2026-08-12 00:26:53] ----------
1. We're doing and updating v3, so it's not v4. 2. I agree with your argument in the last run, so what would be the columns and key classification decision rules?

--- AGENT [2026-08-12 00:27:18] ----------
Right -- v3 hasn't been run, so this is still v3 in draft. Let me fold it in and retire the separate proposal file.

--- AGENT [2026-08-12 00:31:41] ----------
Folded into v3 -- you're right that the version number belongs to what gets *run*, not what gets drafted. The `taxonomy_v4_proposal.md` file is gone; its content is now "v3, final form" inside `taxonomy_decisions.md`, with the superseded priority passages marked in place rather than deleted so the reasoning trail survives.

The columns

Filled by the model -- three judgements plus a verdict:

column	values
`cmte_sector_juris`	0/1 -- a committee has jurisdiction over *this firm's* business
`detail_cmte` . `conf_cmte_sector_juris`	evidence . 1-5
`motive_social_tie`	0/1
`detail_social_tie` . `conf_social_tie`	evidence . 1-5
`motive_other`	0/1
`other_type` . `detail_other` . `conf_other`	controlled vocabulary . evidence (required) . 1-5
`decisive` . `conf_decisive`	which reason actually drove it, or `cannot_say`
`reasoning`, `search_used`, `source_1`-`5`	unchanged

Merged -- the model never touches these: `motive_geography` (firm-cycle-district panel), `cmte_wm_approp` (string match on `cmte_l1`), and the facts already in the sample -- `cand_ici`, `cand_power_l1`, `cand_ever_power_l1`, `n_cmte_l1`.

Derived after the run: `motive_committee = max(cmte_sector_juris, cmte_wm_approp)` . `n_reasons` = the four flags summed . `motive_none` = 1 when `n_reasons` = 0.

The decision rules

1. **No ordering, no first match.** Each reason judged on its own evidence; a donation satisfying two is recorded as satisfying two.
2. **Ask only what the data doesn't already answer.** Geography and W&M/Appropriations membership are merged -- which also keeps the redundancy gate honest, since it now runs on the judged flags alone instead of on a set that includes mechanical ones.
3. **Every tick needs named evidence** in its `detail_` column plus its own confidence.
4. **One 1-5 scale, no ceilings.** The cap on social ties is gone; weak evidence shows up as a 1 or 2. This is what makes `n_reasons` mean anything.
5. **Committee = jurisdiction over *this* firm, or W&M/Appropriations.** Other committees without jurisdiction don't qualify, however powerful the member.
6. **`motive_other` is a positive claim** with a named type -- never a residual.
7. **All flags 0 is a valid outcome** (`motive_none`), expected on roughly a third of rows.
8. **Incumbency and power are facts, not reasons.**

One thing still open

`decisive` is in there on my recommendation, not by decision. It keeps a single treatment variable for the outcome half and is a per-row judgement rather than a global convention -- but `motive_2nd`, the last field asked to carry a secondary judgement, came back `others` on 72% of rows. My recommendation stands: keep it, and treat whether it's informative as a *result* rather than an assumption. Strike it if your coauthor would rather; nothing else in the design depends on it.

The prompt is rewritten but unrun. Before a full pass I'd want a 50-row pilot specifically to check two things the redesign introduces: whether `n_reasons` inflates (box-checking), and whether `motive_other` is being used as a positive claim or quietly as the old residual.

--- AUTHOR [2026-08-12 00:37:48] ----------
So is the the case that the classification columns we're going to use are m_geography, m_cmte_sector_juris, m_wm_approp, m_other_cmte, m_social_tie, m_incumbant, m_contestant, m_other? And for some variables, we can have details for the evidence.

--- AGENT [2026-08-12 00:38:13] ----------
Yes -- every one of those can be a column in the delivered file. But they come from three different places, and one naming point is worth fixing before it hardens.

```
--- AGENT   [2026-08-12 00:39:14] ----------------------------------------
Your set is right -- all of those ship. Two clarifications, both now in `taxonomy_decisions.md` ?5a.

## Only three are asked of the model

|  | model fills | merged | derived |
|---|---|---|---|
| **reasons** | `motive_social_tie`, `motive_other` | `motive_geography` | `motive_committee`, `n_reasons`,
`motive_none` |
| **committee basis** | `cmte_sector_juris` | `cmte_wm_approp` | `cmte_none_relevant` |
| **candidate status** | -- | -- | `is_incumbent`, `is_contestant`, `is_powerful` |

Your `m_other_cmte` is in there as `cmte_none_relevant` -- `n_cmte_l1 > 0` and neither committee flag set. It
earns its place by distinguishing "sits on committees, none relevant" from "holds no committee at all," which
are different situations. But it's computed, not asked.

Details attach to the three judged columns: `detail_cmte`, `detail_social_tie`, `detail_other` (plus
`other_type`), each with its own confidence. Merged and derived columns take no detail and no confidence --
they're facts, not judgements.

## The one thing I'd change in your list: `m_incumbent` -> `is_incumbent`

This looks cosmetic and isn't. **`motive_*` asserts a reason for the donation; `is_*` states a fact about the
candidate.** 90.5% of your sample is incumbents -- `is_incumbent` is a covariate, not a claim about why
anyone gave.

v2 blurred exactly this distinction by making `incumbent_access` a category, and the result is the clearest
failure in the project so far: 29.2% of the sample assigned *because nothing else applied*, with 283 of 292
rows at identical confidence. Naming these `motive_incumbent` would rebuild that confusion inside the schema,
where it's harder to notice than in a category list -- every table of "motive shares" would silently include
a row that means "the candidate exists."

**Nothing is lost by the rename**, because the old categories are recoverable by crossing:

| old category | v3 equivalent |
|---|---|
| `incumbent_access` | `motive_none == 1 & is_incumbent == 1` |
| `contestant_investment` | `motive_none == 1 & is_contestant == 1` |
| `incumbent_powerful` | `motive_none == 1 & is_powerful == 1` |

And that last one actually improves. Under v2 a donation to a powerful member with no firm-specific link was
*assigned* `incumbent_powerful` by elimination. Under v3 it's `motive_none` -- unless someone can argue
agenda-setting power was genuinely the draw, in which case it's `motive_other` with `other_type =
leadership_access` and a confidence attached. The claim now has to be earned rather than inherited.

So: same information, same eight-ish concepts you listed, but the schema no longer implies that being an
incumbent is a reason someone received money.

--- AUTHOR  [2026-08-12 00:42:14] ----------------------------------------
What do you mean "merged" in the table? Can you just give a list of classification columns we plan to use?

--- AGENT   [2026-08-12 00:42:27] ----------------------------------------
"Merged" = the value is joined in from another file, not decided by the model. Let me confirm the list
against what's actually in the prompt so I'm not quoting from memory.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/Guidance" && sed -n '/^### Columns yo

--- AGENT   [2026-08-12 00:42:45] ----------------------------------------
**"Merged"** means the value is joined in from another file -- the model never sees or writes it.
`motive_geography` is a lookup into `firm_cycle_district_2000_2024.parquet` on `gvkey x cycle x district`;
`cmte_wm_approp` is a string match on `cmte_l1`, which is already a column in the sample. Three ways a column
gets filled: **model** writes it, **merged** joins it in, **derived** computes it from other columns.

## The list

**Model writes these -- 15 columns**

| # | column |
|---|---|
| 1 | `cmte_sector_juris` |
```

2	`detail_cmte`
3	`conf_cmte_sector_juris`
4	`motive_social_tie`
5	`detail_social_tie`
6	`conf_social_tie`
7	`motive_other`
8	`other_type`
9	`detail_other`
10	`conf_other`
11	`decisive`
12	`conf_decisive`
13	`reasoning`
14	`search_used`
15	`source_1`-`source_5`

Merged in -- 2 columns

#	column	from
16	`motive_geography`	the firm-cycle-district panel
17	`cmte_wm_approp`	string match on `cmte_l1`

Derived -- 7 columns

#	column	formula
18	`motive_committee`	`max(cmte_sector_juris, cmte_wm_approp)`
19	`n_reasons`	the four `motive_*` flags summed
20	`motive_none`	`n_reasons == 0`
21	`cmte_none_relevant`	`n_cmte_l1 > 0` & both committee flags 0
22	`is_incumbent`	`cand_ici == "I"`
23	`is_contestant`	`cand_ici != "I"`
24	`is_powerful`	`cand_power_l1 == 1`

The four reason flags -- `motive_geography`, `motive_committee`, `motive_social_tie`, `motive_other` -- are the ones the paper's distribution is built on. Everything else is either evidence for them, a component of them, or a covariate.

--- AUTHOR [2026-08-12 00:43:12] ----------
We're updating the rule and will use the rule to classifcation all donation records, so nothing to be merged here.

--- AGENT [2026-08-12 00:43:34] ----------
You're right, and my terminology was the problem. There's no merge step *in the classification* -- those fields are already in the file when the model receives it, exactly as `hq_cd_match_cand` and `cmte_l1` are today. Let me check what the input file currently carries.

[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/AI Talk" && PYTHONIOENCODING=utf-8 py

[action] Write: C:\Users\DevinZ\AppData\Local\Temp\claude\G--OneDrive---The-Pennsylvania-State-University-PhD-research-projects-2026-07-AI---Political-Donation-Motive

[action] Bash: cd "C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-University-PhD-research-projects-2026-07-AI---Political-Donation-Mo

--- AGENT [2026-08-12 00:44:44] ----------
You're right -- "merged" was my word and it misled. There's no merge step in the classification. Those fields are built into the classification file *before* the run, exactly as `hq_cd_match_cand` and `cmte_l1` already are, and the model reads them as supplied facts. Corrected throughout to **supplied / written / computed**.

The classification columns

Written by the model -- 15

`cmte_sector_juris` . `detail_cmte` . `conf_cmte_sector_juris` . `motive_social_tie` . `detail_social_tie` . `conf_social_tie` . `motive_other` . `other_type` . `detail_other` . `conf_other` . `decisive` . `conf_decisive` . `reasoning` . `search_used` . `source_1`-`5`

Supplied in the file, read not written -- 2 new

`motive_geography` . `cmte_wm_approp`

(alongside the ones already there: `cand_ici`, `cmte_l1`, `cand_power_l1`, `hq_cd_match_cand`, ...)

Computed after the run -- 7

`motive_committee` . `n_reasons` . `motive_none` . `cmte_none_relevant` . `is_incumbent` . `is_contestant` . `is_powerful`

One thing this surfaces, which is a build task rather than a wording one

The current classification input file -- `AI Talk/random_1000_house_firm_cand_cycle_don_for_classification.csv`, 45 columns -- carries `hq_cd_match_cand` (the old HQ-only flag) and carries **neither** `motive_geography` **nor** `cmte_wm_approp`. It also still has the v1/v2 output columns (`motive`, `motive_detail`, `motive_2nd`, `confidence`).

So before any v3 run that file has to be rebuilt:

add	how
`motive_geography`	join `Data/firm_cycle_district_2000_2024.parquet` on `gvkey x cycle x cand_office_st x cand_office_district`; 1 where `in_hq == 1 or in_estab_500 == 1`
`cmte_wm_approp`	`cmte_l1` contains "ways and means" or "appropriation"

and swap the four v1/v2 output columns for the v3 blanks. That's an update to `AI Talk/2.add_committee_fields_and_classification_columns.do`, which hasn't been done.

I'd keep `hq_cd_match_cand` in the file rather than replacing it -- it's the narrow HQ-only measure, and having both lets you report the establishment-based geography against the original as a robustness contrast.

--- AUTHOR [2026-08-12 00:45:31] ----------
We're determining the taxonomy, so that we can use it for the exercise. The expanation columns should come after those category values

[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
↪ Political Donation Motive" && cat >> STATUS_MEMO.md <<'EOF' ##

--- AGENT [2026-08-12 00:49:52] ----------

Both points handled.

The schema was too wide -- cut from 19 to 10

Three cuts, none of which loses information:

A reason and its confidence are now one column. `0` = doesn't apply, `1`-`5` = applies at that confidence. Six columns become three, and it becomes impossible to record a reason without saying how sure you are -- which was a real failure mode in the two-column version.

`decisive` and `conf_decisive` dropped. They only carried information when more than one reason fired -- 1.4-8.1% of rows -- and merely restated the single flag everywhere else. Where two reasons apply and one dominated, that goes in `reasoning`, which is being written anyway. That also settles the open question from earlier today, in the direction of *not* keeping the field.

`source_1`-`source_5` -> one `sources` column, semicolon-separated, with `search_used` computed from whether it's blank.

Final: 10 columns.

A. category values	B. evidence
`motive_geography` *(supplied)*	`other_type`
`cmte_wm_approp` *(supplied)*	`detail_cmte`
`cmte_sector_juris_conf`	`detail_social_tie`
`social_tie_conf`	`detail_other`
`other_conf`	`reasoning` . `sources`

A typical row -- one reason, nothing else -- costs **four values**: one confidence, two zeros, one detail, one sentence.

And you're right that v1/v2 don't belong in the prompt

They're inputs to v3's *design*, not guidance the model needs -- and the prompt's own opening line says it contains nothing researcher-facing. I'd drifted into citing them ("v2 offered them as categories; they absorbed 43% of donations... 283 of 292 rows at identical confidence"), which spends the model's attention without changing what it should do. A rule justified by what a previous round found is a rule the model can't act on any differently for knowing.

Each is now an instruction that stands alone:

was	now
"v2 offered them as categories; they absorbed 43%..."	"Nearly every candidate in this data is one of those things, so treating it as a reason would explain every donation equally and therefore none of them"
"in the v1 round the model simply echoed the district indicator back"	"It is supplied because the data already settles it"
"in the trial sample 91 pairs shared an institution but only 22 overlapped"	"An institution match without a time overlap is usually just a large university"

The empirical record stays in `taxonomy_decisions.md`, which is where someone asking *why* a rule exists should look. The prompt is 345 lines and self-contained.

--- AUTHOR [2026-08-12 00:51:42] ----------
1. Why does only "motive_geography" have the word of "motive"? I think the column names should be consistent?
2. Would it be better to have incumbent, contestant, other_cmte, and powerful columns?

--- AGENT [2026-08-12 00:52:15] ----------
Both fair. On (1) the inconsistency is mine, and on (2) they're already in the file -- but one of them is a pure duplicate I should remove.

[action] Write: C:\Users\DevinZ\AppData\Local\Temp\claude\G--OneDrive---The-Pennsylvania-State-Universit⌋
↪ y-PhD-research-projects-2026-07-AI---Political-Donation-Motive

[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
↪ Political Donation Motive" && sed -i 's/`motive_none == 1 \& is

```
--- AGENT   [2026-08-12 00:53:16] ----------------------------------------
## 1. Fixed -- one scheme now

You're right, it was inconsistent. **Every reason column is `motive_*`.** The three you fill end in `_conf`
because they carry a confidence; the two supplied ones don't, because they're facts rather than judgements.

| | column | values |
|---|---|---|
| **supplied** | `motive_geography` | 0/1 |
| | `motive_cmte_wm_approp` | 0/1 |
| **model fills** | `motive_cmte_sector_juris_conf` | 0 = no; 1-5 = yes at that confidence |
| | `motive_social_tie_conf` | same |
| | `motive_other_conf` | same |
| **computed** | `motive_committee` . `n_motives` . `motive_none` | |

Anything named `cand_*` describes the candidate and is not a reason -- that boundary is now visible in the
names themselves. `n_reasons` -> `n_motives` to match.

## 2. All four are already there -- and one was a duplicate I should have caught

| you asked for | in the file as | source |
|---|---|---|
| incumbent | `cand_incumbent` | computed from `cand_ici` |
| contestant | `cand_contestant` | computed from `cand_ici` |
| other committee | `cmte_none_relevant` | computed: holds committees, none qualifying |
| powerful | **`cand_power_l1`** | **already in the sample** |

I'd had `is_powerful` in the computed list defined as `cand_power_l1 == 1` -- which is an exact copy of a
column that already exists, under a new name. Deleted. Use `cand_power_l1`.

The other three are genuinely worth computing, and they cost nothing. To be clear about why they're not
*asked* of the model: it's cost per row and an extra failure mode, not a judgement that the information is
uninteresting. The sample already answers all four, so asking would buy nothing and spend attention that
should go to the three real judgements.

--- AUTHOR  [2026-08-12 00:57:59] ----------------------------------------
If we have the word of "motive" for all classifications, we can drop it to make the variable name shorter.
Therefore, the motive columns are: geography, cmte_sector_juris, cmte_wm_approp, cmte_none_relevant,
social_tie, other. The columns is_incumbent and is_contestant can be computed from cand_ici, and
cand_powerful_l1 is already in the sample. Is this understanding correct?

--- AUTHOR  [2026-08-12 00:58:54] ----------------------------------------

## The columns
```

	column	values
supplied	`geography`	0/1
	`cmte_wm_approp`	0/1
model fills	`cmte_sector_juris_conf`	0 = no; 1-5 = yes at that confidence
	`social_tie_conf`	same
	`other_conf`	same
evidence	`other_type` . `detail_cmte` . `detail_social_tie` . `detail_other` . `reasoning` . `sources`	
computed	`committee` . `n_motives` . `no_motive` . `cmte_none_relevant` . `cand_incumbent` . `cand_contestant` . `search_used`	

And yes -- `cand_incumbent` / `cand_contestant` come from `cand_ici`, and `cand_power_l1` is already in the sample.

The two refinements

I kept `_conf` on the three the model fills. They run 0-5, while `geography` and `cmte_wm_approp` are 0/1. Without the suffix the two scales look identical in a variable list, and anyone filtering `social_tie == 1` would silently get *only the confidence-1 ties* -- the weakest ones -- while thinking they'd selected all of them. The suffix is the cheapest possible guard against a bug that would be very hard to spot in a results table.

`cmte_none_relevant` isn't a motive, so I've kept it out of the motive block. It's the *absence* of a qualifying committee -- the candidate holds seats, none of which qualify. It stays in the file as a computed diagnostic, sitting with the candidate facts, and it's excluded from `n_motives`. Otherwise a donation could score a motive for having no motive.

I also dropped two computed dummies I'd had (`motive_social_tie`, `motive_other`) -- `social_tie_conf > 0` already *is* the dummy, so they were duplicates.

Where v3 now stands

The prompt is self-contained, ten columns for the model, no version history, no priority order. What hasn't been done: **the classification input file still needs rebuilding** -- it carries `hq_cd_match_cand` and the old v1/v2 output columns, and needs `geography` and `cmte_wm_approp` added plus the new blanks. That's an update to `AI Talk/2.add_committee_fields_and_classification_columns.do`.

After that I'd run a 50-row pilot before the full pass, to check the two things this redesign introduces: whether `n_motives` inflates from box-checking, and whether `other_conf` is being used as a positive claim rather than quietly as the old residual.

--- AUTHOR [2026-08-12 01:03:51] ----------

--- AGENT [2026-08-12 01:05:38] ----------

I was churning on the schema instead of answering your question. Stopping.

Direct answer: six columns, and yes, an LLM handles that fine. The v1 and v2 runs already filled nine per row across 1,000 rows without trouble. Six is comfortably under that.

The model fills:

column	
`cmte_sector_juris_conf`	0 = no, 1-5 = yes at that confidence
`social_tie_conf`	same
`other_conf`	same
`other_type`	blank unless `other_conf > 0`
`evidence`	<=2 sentences
`sources`	blank unless it searched -- so blank on ~90% of rows

A typical row is **four values**: one confidence, two zeros, one sentence.

Two columns arrive already filled (`geography`, `cmte_wm_approp`). Two are computed afterwards (`committee`, `n_motives`). **Nothing else is stored** -- `no_motive`, `cmte_none_relevant`, `cand_incumbent`, `search_used` were all one-liners from columns that already exist, and I'd been listing them as if they were deliverables. That was the sprawl you kept seeing, and it was my error, not a requirement of the design.

Could it go lower than six? Only by folding `other_type` and `sources` into the prose -- which would cost the finer "other" breakdown you asked for, and the source trail the AFA appendix needs. So six is about the floor.

The taxonomy and columns are settled. What's actually left before a run:

1. Rebuild the classification input file -- it still has `hq_cd_match_cand` and the v1/v2 output columns, and needs `geography` + `cmte_wm_approp` added.
2. Run 50 rows as a pilot, check whether `n_motives` inflates.
3. Full run.

Want me to do (1)?

--- AUTHOR [2026-08-12 01:06:09] ----------
Why do you continue throwing me so much information and columns? Do we nee so many columns? I simply want to confirm taxonomy and columns for the exercise

--- AGENT [2026-08-12 01:06:16] ----------
You're right. I kept adding instead of answering.

Six columns. That's the answer.

```
cmte_sector_juris_conf    0-5
social_tie_conf           0-5
other_conf                0-5
other_type                text, usually blank
evidence                  1-2 sentences
sources                   usually blank
```

Taxonomy: four motives, unranked, any number can apply.

```
geography . committee . social tie . other
```

Geography and Ways-and-Means/Appropriations arrive already filled in the file -- the model doesn't touch them. `committee` and `n_motives` get computed after. That's everything.

Yes, an LLM handles six columns fine. Your v1 and v2 runs filled nine.

The earlier lists were me enumerating things that get computed in one line at analysis time -- they were never columns anyone fills. That was noise I generated, and I should have said "six" the first time you asked.

--- AUTHOR [2026-08-12 01:07:23] ----------
why do you remove cmte_wm_approp???

--- AGENT [2026-08-12 01:07:30] ----------
It's not removed -- it's in the file. I listed only the six the *model* fills, which made it look gone.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance" && grep -n "cmte_wm_approp"

--- AGENT [2026-08-12 01:07:42] ----------
Still there. The full column list:

```
geography                 0/1   <- already in the file
cmte_wm_approp            0/1   <- already in the file
cmte_sector_juris_conf    0-5   <- model
social_tie_conf           0-5   <- model
other_conf                0-5   <- model
other_type                text  <- model
evidence                  text  <- model
sources                   text  <- model
committee                 0/1   <- computed
n_motives                 0-4   <- computed
```

`cmte_wm_approp` is a string match on `cmte_l1` -- "does the candidate sit on Ways and Means or Appropriations." There's nothing to judge, so it's filled when the file is built, not by the model. Same reason `geography` is pre-filled.

The six I listed were only the ones the model writes. My phrasing was wrong.

--- AUTHOR [2026-08-12 01:10:25] ----------
1. why does cmte_sector_juris have _conf? 2. What does other_type mean? 3. What are the all columns we want LLMs to fill?

--- AGENT [2026-08-12 01:10:35] ----------
1. Because it's not a 0/1 dummy -- it's 0-5.

```
0     no committee has jurisdiction over this firm
1-5   one does, at that confidence
```

I merged the flag and its confidence into one column to cut the count. The `_conf` suffix is a warning label: filter `> 0`, not `== 1`, or you'd get only the weakest cases.

If you'd rather have a plain 0/1 `cmte_sector_juris` plus a separate confidence column, that works too -- it's one more column per motive, three more overall.

2. `other_type` is what kind of "other".

When `other_conf > 0`, the model names the kind:

`leadership_access` . `ideology` . `state_delegation` . `bill_sponsorship` . `trade_association` . `relationship_maintenance` . `constituent_executive`

This is the finer breakdown you asked for, so "other" isn't an opaque bucket you can't analyse. Blank when `other_conf = 0`.

3. Six columns:

```
cmte_sector_juris_conf
social_tie_conf
other_conf
other_type
evidence
sources
```

--- AUTHOR [2026-08-12 01:13:41] ----------
1. Why could we have "no committee has jurisdiction over this firm" for cmte_sector_juris_conf? 2. where did you get the idea of other_type that has leadership_access . ideology . state_delegation . bill_sponsorship . trade_association . relationship_maintenance . constituent_executive? I don't even think we need to have this

variable. We're doing v3 and use v2 as the inputs, why do you keep adding new columns?

--- AGENT [2026-08-12 01:14:09] ----------
Both fair, and the second one lands.

1. Because I merged two different things into one column to save space. `0` is a classification ("no committee has jurisdiction"), `1-5` is a confidence about the opposite classification. That's muddled, and you spotted it. It should just be `cmte_sector_juris` = 0/1.

2. I invented `other_type`. You said you wanted finer information on "other" and I turned that into a seven-item controlled vocabulary drawn from my own reading of the runlog and the deferred ideology decision. You didn't ask for that list and neither did your coauthor. It can go.

And you're right about the pattern. v3 should be v2 plus the changes we actually agreed. Instead I kept designing a new schema. The agreed changes are only these:

- Ways and Means / Appropriations credited on membership
- No priority ordering -- multiple motives can apply
- Incumbent/contestant dropped as categories
- Same confidence bar across motives

Applied to v2's existing columns, that gives:

v2	v3
`motive` *(one value)*	-> `geography`, `committee`, `social_tie`, `other` -- four 0/1 columns
`motive_detail`	keep
`motive_2nd`	drop -- multi-label makes it unnecessary
`confidence`	keep
`reasoning`	keep
`search_used`, `source_1`-`5`	keep

So the model fills: **four motive dummies, `motive_detail`, `confidence`, `reasoning`, `search_used`, `source_1`-`5`** -- the same shape as v2, with the single `motive` column replaced by four dummies.

The one open question the coauthor raised: whether `confidence` stays a single value for the row, or becomes one per motive. A single value is v2's shape and fewer columns; per-motive is what makes `n_motives` strictly comparable. That's your call, and it's the only thing still genuinely undecided.

Nothing edited this turn. Tell me which way on confidence and I'll write it.

--- AUTHOR [2026-08-12 01:15:54] ----------
I'm thking about this classification: The motive columns: geography, cmte_sector_juris, cmte_wm_approp, cmte_none_relevant, social_tie, other.

The columns is_incumbent and is_contestant can be computed from cand_ici, and cand_powerful_l1 is already in the sample.
. What do you think?

--- AGENT [2026-08-12 01:16:16] ----------
That works. My only quibble was that `cmte_none_relevant` is the *absence* of a motive rather than a motive -- but it's free to compute, it makes the committee logic readable at a glance, and you've now asked for it three times. Keep it. Just don't count it when tallying how many motives a donation has.

Who fills the six:

column	filled by
`geography`	in the file already
`cmte_wm_approp`	in the file already (string match on `cmte_l1`)
`cmte_none_relevant`	computed
`cmte_sector_juris`	**model**
`social_tie`	**model**
`other`	**model**

So the model judges three things. And yes -- `is_incumbent` / `is_contestant` from `cand_ici`, `cand_power_l1` already in the sample.

Two small things worth settling, then it's done:

`other` with no type column. Whatever the reason was goes in the detail text. Fine, and simpler than a controlled vocabulary -- you just can't tabulate the kinds of "other" without reading them. Acceptable if "other" stays rare.

Confidence. One value for the row (v2's shape), or one per motive. Your coauthor's point was that `n_motives` only means something if the bar is the same across motives -- which a single row-level confidence doesn't guarantee. But per-motive is three more columns. That's the last open call.

--- AUTHOR [2026-08-12 01:19:15] ----------
We're doing the v3 taxonomy and columns to fill planning.

--- AGENT [2026-08-12 01:19:26] ----------
Taxonomy v3

Four motives. Unranked -- any number can apply to one donation.

```
geography . committee . social_tie . other
```

`committee` fires on either of two bases: a committee with jurisdiction over the firm, or membership of Ways and Means / Appropriations.

Dropped from v2: `incumbent_powerful`, `incumbent_access`, `contestant_investment`. They're candidate facts, already in `cand_ici` and `cand_power_l1`.

Columns

Motive columns -- six:

	filled by
`geography`	in the file
`cmte_sector_juris`	**model**
`cmte_wm_approp`	in the file
`cmte_none_relevant`	computed
`social_tie`	**model**
`other`	**model**

Everything else the model fills, unchanged from v2:

`motive_detail` . `confidence` . `reasoning` . `search_used` . `source_1`-`5`

Computed after: `n_motives`, `is_incumbent`, `is_contestant`.

One thing still open: whether `confidence` is one value for the row (v2's shape) or one per motive.

Say which, and I'll write the taxonomy file and the prompt to match. Nothing else outstanding.

--- AUTHOR [2026-08-12 01:19:37] ----------
Is somethign is running? why does it show "1 shell still running"?

--- AGENT [2026-08-12 01:19:47] ----------
Yes -- a leftover wait-loop of mine. Let me find and stop it.
      [action] ToolSearch: select:TaskList,TaskStop
      [action] TaskStop:

--- AGENT [2026-08-12 01:19:56] ----------
Stopped. It was a wait-loop I started during the shapefile download, watching `cd_download.log` for the cd119 completion line. That first download run died partway through (the TIGER2021 layout bug), so the line it was waiting for never appeared -- and the loop kept polling every 20 seconds ever since. The retry wrote to a different log, `cd_download2.log`, which is why the work finished fine while this watcher sat there.

Nothing was running that mattered. The shapefiles, the establishment panel, and the district panel all completed and are committed.

Back to v3 -- the only thing I need from you is whether `confidence` is one value per row or one per motive, and then I'll write the taxonomy file and prompt to match.

--- AUTHOR [2026-08-12 01:21:10] ----------

1. What do you mean "in the file"? 2. We need to discuss and decide the best taxonomy we want to use.

--- AGENT [2026-08-12 01:21:37] ----------
1. "In the file" = the column is already populated in the classification CSV before the model sees it -- same as `cand_ici`, `cmte_l1`, `hq_cd_match_cand` are today. The model reads it as a fact and doesn't write it.

2. Here's what I think is actually still open on the taxonomy, with my view on each.

Is `committee` one motive or two?

The two bases are different economic stories. Sector jurisdiction is *this committee regulates my business*. Ways and Means / Appropriations is *this member sits where tax and spending get decided*. The first is firm-specific, the second is available to every firm.

My view: keep them as two columns and let "committee" be an aggregate you can form or not. That's what the current design does, and it means you don't have to decide now -- you can report either way and see which behaves.

Is `geography` one motive or two?

Same question. HQ is where the executives and the corporate identity are. A 500-person plant is where the workers and votes are. Members respond to those differently, and the literature treats them differently.

My view: worth splitting, since the panel already has `in_hq` and `in_estab_500` separately. It costs nothing and you can always collapse.

Does `social_tie` survive at ~0.6%?

Six rows in 1,000. It can't support analysis on its own.

My view: keep it. It's the one motive no structured dataset can produce, so it's where an LLM does something a merge cannot -- and its rarity is itself a finding against the "personal connections" story. But go in expecting to report it as a null, not as a result.

Do you want `other` at all?

My view: yes for this round. It's the only way to discover a motive the four categories miss, which is exactly what a first pass should be for. If it comes back near-zero, drop it in v4 and you've learned something.

Should `ideology` be a fifth motive?

Multi-label removes the objection that blocked it twice -- with no priority rule, overlap with committee is just recorded rather than resolved by convention.

But it needs the firm's partisan concentration at t-1, which isn't built. So adding it is a decision to build that variable first. If you want it, that's the one piece of real data work left before a run.

Which of these do you want to settle?

--- AUTHOR [2026-08-12 01:38:08] ----------
The motive fields I have in mind are: geography, cmte_sector_juris, cmte_wm_approp, cmte_other, social_tie, and other.
We can also compute is_incumbent and is_contestant from cand_ici, and cand_powerful_l1 is already in the sample.

My idea is we capture slightly more granular information during the initial classification exercise, as we can always aggregate these categories later. What do you think?

--- AUTHOR [2026-08-12 01:38:20] ----------
The motive fields I have in mind are: geography, cmte_sector_juris, cmte_wm_approp, cmte_other, social_tie, and other.
We can also compute is_incumbent and is_contestant from cand_ici, and cand_powerful_l1 is already in the sample.

My idea is we capture slightly more granular information during the initial classification exercise, as we can always aggregate these categories later. What do you think? One question: do you think it would be better to include or exclude the cmte_other column?

--- AGENT [2026-08-12 01:38:48] ----------
Your granularity principle is right, and it applies cleanly here because only three of the six need a judgement -- `cmte_sector_juris`, `social_tie`, `other`. The other three come free. Granularity is cheap when it's computed or supplied; it's expensive only when it costs the model attention per row.

On `cmte_other`: include it, but compute it rather than asking for it.

It's exact -- `n_cmte_l1 > 0 & cmte_sector_juris == 0 & cmte_wm_approp == 0` -- so asking the model would be paying for something you already know.

The reason to have it isn't as a motive. It's as **the denominator that tells you whether the jurisdiction judgement is working.** In v2, 896 rows had a committee and `committee` was assigned to 58.5% of them -- so roughly 41% of committee-holders were judged to have no relevant committee. That number is the single most informative diagnostic in the exercise:

- if it's *too high*, the model is under-detecting jurisdiction
- if it's *too low*, it's crediting committees loosely to avoid saying "no reason"
- and it's the exact subset the redundancy gate needs, since a jurisdiction call is the only part of `committee` that isn't mechanical

Without the column you'd have to reconstruct that every time you wanted to check.

One thing to keep straight: `cmte_other` inherits the model's errors. If the model misses a jurisdiction match, `cmte_other` fires wrongly. So it's a diagnostic, not independent evidence -- read it as "the model found no relevant committee here," not "there is none."

So the six fields work as you have them:

`geography`	in the file
`cmte_sector_juris`	**model**
`cmte_wm_approp`	in the file
`cmte_other`	computed
`social_tie`	**model**
`other`	**model**

Plus `is_incumbent` / `is_contestant` from `cand_ici`, and `cand_power_l1` already there.

--- AUTHOR [2026-08-12 01:40:55] ----------
Would it be cleaner and better to not include the cmte_other column?

--- AGENT [2026-08-12 01:41:09] ----------
Yes. I'd exclude it.

Two reasons that beat the convenience:

It isn't a motive. Five motive fields plus one that means "no motive from committees" is a wart in the list -- and it would show up in every table of motive frequencies as a row that isn't one.

A stored derived column can go stale. If `cmte_sector_juris` is ever revised -- a second coding pass, a corrected row -- `cmte_other` is silently wrong unless someone remembers to recompute it. A one-line derivation can't drift.

My diagnostic argument still holds, but it doesn't need a stored column. `n_cmte_l1 > 0 & cmte_sector_juris == 0 & cmte_wm_approp == 0` goes in the QC script, where it's computed fresh each time from whatever the current labels are -- which is exactly what you want for a check.

So the motive fields are five:

```
geography . cmte_sector_juris . cmte_wm_approp . social_tie . other
```

Model judges three: `cmte_sector_juris`, `social_tie`, `other`. The other two arrive in the file.

Plus `is_incumbent` / `is_contestant` from `cand_ici`, and `cand_power_l1` already in the sample.

--- AUTHOR [2026-08-12 01:43:22] ----------
I agree with your argument. And this is what I want the LLMs to do: multi-motive + checkbox approach is

better. This allows us to flag each applicable motive independently and there will be no need for a priority ordering.

--- AUTHOR [2026-08-12 01:43:46] ----------
I agree with your argument. And this is what I want the LLMs to do: multi-motive + checkbox approach is better. This allows us to flag each applicable motive independently and there will be no need for a priority ordering. So there is no ordering priority for the v3 exercise.

--- AGENT [2026-08-12 01:43:58] ----------
Settled. Writing it into the files now.

--- AGENT [2026-08-12 01:45:51] ----------
Written. v3 is settled in both files.

Taxonomy -- five checkboxes, ticked independently, no ordering:

```
geography . cmte_sector_juris . cmte_wm_approp . social_tie . other
```

All five zero is a valid answer, and the prompt says so explicitly so the model doesn't reach for `other` to avoid it.

The model fills eight columns: the three checkboxes it judges (`cmte_sector_juris`, `social_tie`, `other`), plus `motive_detail`, `confidence`, `reasoning`, `search_used`, `source_1`-`5` -- all unchanged from v2. `geography` and `cmte_wm_approp` arrive already populated.

`cmte_other` is out, as you suggested. It survives as the QC diagnostic -- the share of committee-holders judged to have no relevant committee -- computed fresh in the check rather than stored.

One thing I defaulted on: `confidence` stayed as one value per row, matching v2. That's ambiguous when two motives fire, which is 1.4-8.1% of rows depending on the geography measure. I've recorded it as the open question rather than deciding it for you -- it's the only thing left undecided in the taxonomy.

Next: the classification input file still needs rebuilding -- it carries `hq_cd_match_cand` and the v1/v2 output columns, and needs `geography` + `cmte_wm_approp` added with the v3 blanks. Then a 50-row pilot before the full pass.

--- AUTHOR [2026-08-12 01:52:08] ----------
Now that we decide can have the LLMs check off the following categories: geography, cmte_sector_juris, cmte_wm_approp, social_tie, and other, plus is_incumbent, is_contestant, powerful_cand_l1. Let's look at the supportive columns: motive_detail, confidence, reasoning, search_used, source_1-5. Do we need to adjust any of the supportive columns? What's your suggestion on the confidence column?

--- AGENT [2026-08-12 01:52:41] ----------
Quick note first: `is_incumbent`, `is_contestant` and `cand_power_l1` don't need the LLM -- they're computed from `cand_ici` and already in the sample. They'll be in the file, just not filled by the model.

On the supporting columns, two suggestions:

Collapse `source_1`-`5` to one `sources` column

Five columns for something used on 9.2% of rows in v2, semicolon-separated instead. Saves four columns and loses nothing -- you're never analysing "source 3" as a distinct field.

Keep `search_used` though. It looks redundant with sources being blank, but it isn't: it separates *searched and found nothing* from *didn't search*. That's a real distinction when auditing.

`motive_detail` and `reasoning` both earn their place -- detail is *what* (which committee, which school, which gap), reasoning is *why*. Keep one detail column with semicolons between motives rather than one per motive.

Confidence -- my suggestion: keep one column, but define it precisely

The problem with one row-level confidence is real. If a row has `geography = 1` (supplied, certain) and `social_tie = 1` (a shared campus, weak), a single `confidence = 2` makes the whole row look weak -- and anyone filtering `confidence >= 3` silently drops a certain geography match.

But the fix isn't three confidence columns. Two of the five motives are supplied facts that need no confidence at all, and of the three the model judges, **two firing together should be rare** -- `social_tie` was 0.6% in v2. So the ambiguity is mostly theoretical.

So I'd:

1. **Define `confidence` as applying to the model's judgements only** -- not to `geography` or `cmte_wm_approp`, which are facts. State that in the prompt.
2. **When two judged motives fire at different strengths, give the lower and say why in `reasoning`.**
3. **Make it a QC check**: count rows where two model-judged motives fire. If that's more than a few percent, split confidence in v4 and you'll have the evidence for it.

That keeps v2's shape, avoids three more columns, and makes the limitation explicit rather than hidden. The alternative -- one confidence per judged motive -- is defensible but costs three columns to solve a problem that may affect 1% of rows.

Want me to write these in?

--- AUTHOR [2026-08-12 02:01:51] ----------
1. geography means either donations to a candidate whose district covers either its HQ or has over 250 employees. 2. I agree with your suggestions on confidence and other columns in the last run. I think we can base it and the decisions in the second last run to update v3 and taxonomy_decisions md files.

--- AGENT [2026-08-12 02:02:01] ----------
Noted -- that's **250**, not the 500 we'd settled earlier. Both columns exist in the panel so it's a one-word change, but it moves the geography rate from 8.0% to 11.3% of donations. Flagging so it's a choice, not a slip.

↪ Political Donation Motive" && cat >> STATUS_MEMO.md <<'EOF' ##

--- AGENT [2026-08-12 02:03:10] ----------
Both files updated. v3 as it now stands:

Five motive checkboxes, no ordering

field	1 when	filled by
`geography`	HQ **or** establishments employing **250+** in the candidate's district	in the file
`cmte_sector_juris`	a committee with jurisdiction over this firm	**model**
`cmte_wm_approp`	sits on Ways and Means or Appropriations	in the file
`social_tie`	personal tie to a firm officer/director/gov-affairs lead	**model**
`other`	a specific nameable reason outside the four	**model**

Model fills eight columns: the three checkboxes, plus `motive_detail`, `confidence`, `reasoning`, `search_used`, `sources`.

Changes made this round:

- **Geography at 250** -- flagged above; it takes the trial-sample rate to 11.3%. The earlier 500 evidence isn't overturned, and `in_estab_500` stays in the panel so you can report the tighter cut as a contrast.
- **`source_1`-`5` -> one `sources` column**, semicolon-separated.
- **`search_used` kept** -- it separates *searched and found nothing* from *didn't search*, which blank sources can't.
- **`confidence` scoped** to the three motives the model judges, explicitly not to `geography` or

`cmte_wm_approp`. Where two judged motives differ in strength, it gives the lower and names both in `reasoning`.
- **QC check written down for the next run:** count rows where two model-judged motives fire. If that's more than a few percent, split confidence in v4 with evidence rather than guessing now.

Remaining before a run: rebuild the classification input file to carry `geography` and `cmte_wm_approp` and swap in the v3 output columns, then a 50-row pilot.

--- AUTHOR [2026-08-12 02:05:49] ----------
1. Yes I know it moves the geography rate from 8.0% to 11.3% of donations. But I want to use 250 cutoff. 2. Even if is_incumbent and is_contestant are computed from cand_ici, do we need to have it as a note in v3 prompt in case we forget it after the classification exercise?

--- AGENT [2026-08-12 02:05:59] ----------
Good instinct, but the prompt is the wrong home -- it goes to the model, and you flagged earlier that researcher-facing notes don't belong there. The right place is `run_procedure.md`, which the prompt header already describes as version-independent and not sent to the model. Let me check it.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance" && cat run_procedure.md

--- AGENT [2026-08-12 02:07:01] ----------
1. 250 it is -- already written in, nothing outstanding.

2. Right concern, but I'd put it in `run_procedure.md` rather than the prompt. The prompt goes to the model, and a note saying "we'll compute `is_incumbent` later" tells it nothing -- it's exactly the researcher-facing commentary you flagged earlier. `run_procedure.md` is version-independent, explicitly not part of the prompt, and is what you'd actually consult when processing a run.

New section there -- **After the run, columns to derive:**

column	from
`is_incumbent`	`cand_ici == "I"`
`is_contestant`	`cand_ici != "I"`
`committee`	`cmte_sector_juris == 1 or cmte_wm_approp == 1`
`n_motives`	the motive fields summed

With a note that `cand_power_l1` and `cand_ever_power_l1` are already in the sample and shouldn't be recreated. It opens by saying *why* this step gets forgotten: these are one-liners, so nothing breaks if they're missing -- the file just quietly lacks them.

I also updated the quality checks, which still assumed v2's single `motive` column:

- **Motive count distribution** -- the failure mode of unranked checkboxes is box-ticking. Report `n_motives`; a mean far above ~1.0 means hedging.
- **Two model-judged motives at once** -- precisely the rows where a single `confidence` is ambiguous. Above a few percent, split it in v4.
- **`other` as a residual** -- read every row with `other = 1` and nothing else. Vague detail means the model is dodging an empty row.
- **Redundancy gate on `cmte_sector_juris` alone**, not the whole motive set. `geography` and `cmte_wm_approp` are supplied, so including them would flatter the result by testing the model on facts it was handed. The jurisdiction call is the only thing the model does unaided.

That last change matters for the paper -- the gate is your evidence that the LLM adds something, and running it on supplied fields would have inflated it.

--- AUTHOR [2026-08-12 02:11:54] ----------
1. I agree to have a run_procedure.md. In that file, do we need to remind the LLMs that firm_cycle_district_2000_2024 in \2026.07 AI - Political Donation Motive\Data is the data it should use for geography motive? Also between firm_cycle_district_2000_2024.dta and firm_cycle_district_2000_2024.parquet, which file will save tokens for LLMs to do the exercise? 2. We're do v3. There is no v4. 3. What does "which still assumed v2's single motive column" mean?

--- AGENT [2026-08-12 02:12:08] ----------
1. The LLM never reads that file. `geography` arrives as a column in the classification input file,

already filled -- the panel is used by the *script* that builds that file, not during classification. So no reminder is needed, and the token question doesn't arise. (For the build script, `.parquet` is smaller and faster; `.dta` exists for your Stata work.)

3. The quality checks were written for v2, where there was one column called `motive` holding one of seven values. The redundancy-gate instruction literally said *"cross-tabulate `motive` against the mechanical indicators"* -- but there is no `motive` column any more, there are five 0/1 fields. So the check couldn't be run as written. That's all I meant.

2. You're right, and I've been sloppy about it. Let me fix the references.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && grep -rn "v4\|next version" Guida
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && python - > /dev/null <<'PYEOF' im

--- AGENT [2026-08-12 02:12:46] ----------
All three handled.

1. No pointer needed -- the LLM never touches `firm_cycle_district_2000_2024`. `geography` is a filled column in its input file; the panel is read by the *build script*, where token cost is irrelevant. (For that script `.parquet` is smaller and faster, `.dta` is there for your Stata work. If an LLM ever did need to read a table directly, CSV would be cheapest -- both `.parquet` and `.dta` are binary and unreadable without parsing.)

2. Fixed. Zero "v4" references left in any of the three guidance files. Deferred questions now read "revisit whether confidence should be recorded per motive" -- a version number gets claimed when a run happens, not when a question is deferred.

3. It meant the checks literally couldn't be executed. The redundancy gate said *"cross-tabulate `motive` against the mechanical indicators"*, and there is no `motive` column any more -- there are five 0/1 fields. I rewrote the checks to name the new fields. What they test is unchanged; only the column names are.

Where v3 stands: taxonomy settled, prompt written, run procedure updated with the post-run derivations and the four quality checks. The one thing left before a run is rebuilding the classification input file -- it still carries `hq_cd_match_cand` and the v1/v2 output columns, and needs `geography` and `cmte_wm_approp` added with the v3 blanks.

--- AUTHOR [2026-08-12 02:16:45] ----------
1. But an LLM still need to match firm_cycle_district_2000_2024 data with the cycle-gvkey-candidate record data, right? 2. taxonomy_decisions.md should record the taxonomy decisions for each version. We don't need to record all the details when deciding a version. I feel there are too many contennts about v3 taxonomy in it. Should we trim some parts?

--- AGENT [2026-08-12 02:17:03] ----------
1. No -- the join happens before classification. The build script looks up each `(gvkey, cycle, cand_office_st, cand_office_district)` in the panel and writes `geography = 1/0` into the classification file. The LLM reads that column like any other. Making it do the join would mean putting a 588,000-row panel in its context for a lookup a script does exactly.

2. Yes, it's bloated -- that's my doing. Let me see how bad.
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive/Guidance" && awk '/^## v1/{v1=NR} /^#

--- AGENT [2026-08-12 02:17:30] ----------
192 lines against 48 for v1 and 130 for v2 -- and most of it is my drafting history, not decisions. Trimming to match the file's stated purpose.
[action] Write: C:\Users\DevinZ\AppData\Local\Temp\claude\G--OneDrive---The-Pennsylvania-State-University-PhD-research-projects-2026-07-AI---Political-Donation-Motive

[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && python - > /dev/null <<'PYEOF' P=

--- AGENT [2026-08-12 02:19:02] ----------
The LLM doesn't check `geography` -- it reads it. The value is already in the row when the row reaches the model.

A row of the classification file looks like this:

```
gvkey  cycle  conm            cand_nm        cmte_l1                         geography  cmte_wm_approp
cmte_sector_juris  social_tie  other  ...
1234   2012   REGIONS FINL    bachus, spencer  financial services (chair)        0             0
[blank]      [blank]  [blank]
```

`geography` and `cmte_wm_approp` arrive filled. The model fills the blanks. It never computes geography, never opens the panel, never does a join.

Where the join actually happens: in the script that builds this file. For each donation row it looks up `(gvkey, cycle, cand_office_st, cand_office_district)` in `firm_cycle_district_2000_2024.parquet` and writes `geography = 1` if that tuple has `in_hq = 1` or `in_estab_250 = 1`, else 0. One merge, 1,000 rows, done once -- the same way `cmte_l1` and `hq_cd_match_cand` already get into the file today.

The model does *see* `geography`, and that's deliberate: if geography is 1 and the candidate also chairs a relevant committee, the model should mention both in `reasoning`. But it's context, not a task.

That's also why the `.dta` vs `.parquet` question doesn't arise -- nothing about the panel enters the model's context. The build script reads the parquet.

Separately: the taxonomy file is trimmed. v3 went from 192 lines to 60 -- the five motive fields plus the decisions that shaped them, with a pointer to `STATUS_MEMO.md` for trial-sample counts and superseded reasoning. v1 and v2 untouched, since they record versions that were actually run.

--- AUTHOR [2026-08-12 03:34:48] --
One comment I received is the memory issue of LLMs when I ask it to do the classification for the full sample. I think people ask about this question because they worry about how much the classification exercise is reproducible. Do we have such issues when I apply the classification_prompt_v3 to the full sample? Is there a way to somehow alleviate this issue?

--- AGENT   [2026-08-12 03:35:22] --
Real issue, and it's the right thing for people to press on. Let me check the scale first, because the answer depends on it.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2024.12 Supply

--- AGENT   [2026-08-12 03:35:49] --
520,011 rows -- that changes the answer. Let me check one thing that determines the best fix.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪ Political Donation Motive/AI Talk" && PYTHONIOENCODING=utf-8 py

--- AGENT   [2026-08-12 03:36:21] --
That's the answer, though not as dramatic as I hoped -- on a random 1,000 the dedup is only 32%, because random draws rarely repeat. On the full 520k it would be far larger, since the same firm gives to many candidates and vice versa.

--- AGENT   [2026-08-12 03:37:44] --
Yes, it's a real problem, and it's the right thing for people to press on. Written up as `run_procedure.md` ?3.

The scale that creates it

The full donation master is **520,011 firm-candidate-cycle rows** (1,592 firms, 3,918 candidates, 12 cycles). Nothing that size fits in one context, so you batch -- and batching is what breaks reproducibility:

A row classified after 400 other rows is not being classified the way the same row seen first would be. The model becomes internally consistent within a batch -- having decided how to treat a Ways and Means member for one firm, it carries that forward -- and that consistency doesn't transfer across batches. Same row, different batch position, potentially different label. That's the memory issue, and it's genuine.

(Two smaller ones: non-determinism even at temperature 0, and model drift -- `claude-opus-5` in six months isn't the same object.)

The fix is structural, not statistical

The judged fields don't depend on the donation. `cmte_sector_juris` is a function of *(the firm's business, the candidate's committee set)* -- the dollar amount and the timing play no part. Two donations sharing an industry and a committee set have the same answer by construction.

So classify the **distinct pairs**, not the rows:

```
1. build the distinct set of (hist_gics4, cmte_l1) pairs observed
2. classify each once, in its own fresh context
3. join the labels back onto all 520,011 rows
```

The point isn't cost -- it's that **identical inputs cannot receive different labels, because they aren't classified twice.** Order dependence disappears for the largest judged field outright, rather than being measured and hoped small.

On cost, be careful of my earlier optimism: on a random 1,000-row draw the dedup is only **32%** (679 distinct pairs), because random draws rarely repeat. On the full sample it'll be much larger -- the same firm gives to many candidates -- but measure it before budgeting.

For whatever can't be deduplicated: **one call per unit, fresh context.** Never stream many rows through one conversation. It's cheaper per row and it destroys exactly the property you need to defend. The prompt is ~350 lines, so repeating it is cheap, and the work parallelises trivially.

What to report

Reproducibility can't be asserted, only quantified. Four numbers:

- **Rerun agreement** on a random 200, second independent run -- this is the ceiling on any accuracy claim
- **Order effect** -- same 200 classified first vs last in a batch. Under per-unit calls this should be *exactly* 100%, which is the point of showing it
- **Dedup consistency** -- 100% by construction, verified anyway because it catches pipeline bugs
- **Search sensitivity** -- search results are time-varying and are the least reproducible input

That turns the commenter's worry from an objection into a reported measurement, which is the strongest available answer for the AFA paper.

--- AUTHOR [2026-08-12 03:52:46] ----------
So I think classification_prompt_v3.md is good to use? Then given you suggestions in the last run, how should I use claude for this classification exercise?

--- AGENT [2026-08-12 03:52:57] ----------
Two things before answering: the prompt is written, but the exercise isn't runnable yet -- the classification input file still needs rebuilding. And since you're asking how to actually drive Claude at this scale, let me check the current API facts rather than answer from memory.
[action] Skill:

--- AUTHOR [2026-08-12 03:53:00] ----------
Base directory for this skill:

Building LLM-Powered Applications with Claude

This skill helps you build LLM-powered applications with Claude. Choose the right surface based on your needs, detect the project language, then read the relevant language-specific documentation.

Before You Start

Scan the target file (or, if no target file, the prompt and project) for non-Anthropic provider markers -- `import openai`, `from openai`, `langchain_openai`, `OpenAI(`, `gpt-4`, `gpt-5`, file names like `agent-openai.py` or `*-generic.py`, or any explicit instruction to keep the code provider-neutral. If you find any, stop and tell the user that this skill produces Claude/Anthropic SDK code; ask whether they want to switch the file to Claude or want a non-Claude implementation. Do not edit a non-Anthropic file with Anthropic SDK calls. (Exception: the `prompt-audit` subcommand is non-interactive and does not stop here -- it records non-Anthropic provider markers in its report's stated assumptions and never proposes switching a

```
non-Anthropic file to the Anthropic SDK.)

## Output Requirement

When the user asks you to add, modify, or implement a Claude feature, your code must call Claude through one
of:

1. **The official Anthropic SDK** for the project's language (`anthropic`, `@anthropic-ai/sdk`,
`com.anthropic.*`, etc.). This is the default whenever a supported SDK exists for the project.
2. **Raw HTTP** (`curl`, `requests`, `fetch`, `httpx`, etc.) -- only when the user explicitly asks for
cURL/REST/raw HTTP, the project is a shell/cURL project, or the language has no official SDK.

Never mix the two -- don't reach for `requests`/`fetch` in a Python or TypeScript project just because it
feels lighter. Never fall back to OpenAI-compatible shims.

**Never guess SDK usage.** Function names, class names, namespaces, method signatures, and import paths must
come from explicit documentation -- either the `{lang}/` files in this skill or the official SDK repositories
or documentation links listed in `shared/live-sources.md`. If the binding you need is not explicitly
documented in the skill files, WebFetch the relevant SDK repo from `shared/live-sources.md` before writing
code. Do not infer Ruby/Java/Go/PHP/C# APIs from cURL shapes or from another language's SDK.

**If WebFetch or repository access fails** (network restricted, timeouts, clone blocked): do not keep
retrying -- write code from the patterns and namespace/package tables in the `{lang}/` file, run the compiler
or interpreter on it, and iterate on the error output. For statically-typed SDKs (C#, Java, Go) a compile-fix
loop against local errors reaches working code faster than blocked network research.

## Defaults

Unless the user requests otherwise:

For the Claude model version, please use Claude Opus 5, which you can access via the exact model string
`claude-opus-5`. Please default to using adaptive thinking (`thinking: {type: "adaptive"}`) for anything
remotely complicated. And finally, please default to streaming for any request that may involve long input,
long output, or high `max_tokens` -- it prevents hitting request timeouts. Use the SDK's
`.get_final_message()` / `.finalMessage()` helper to get the complete response if you don't need to handle
individual stream events

## ?? API Drift -- Your Training Prior May Be Stale

Several common Claude API shapes changed in 2025-2026. If you recall a pattern from training, verify it
against the `{lang}/` files in this skill before writing -- the rows below are the most frequent drift points:

| Area | Stale prior | Current API |
|---|---|---|
| Extended thinking | `thinking: {type: "enabled", budget_tokens: N}` | On Claude 4.6+ models: `thinking:
{type: "adaptive"}`. `budget_tokens` is deprecated on Opus 4.6 / Sonnet 4.6 and **rejected with a 400** on
Fable 5 / Sonnet 5 / Opus 5 / 4.8 / 4.7. Pre-4.6 models still use `budget_tokens`. |
| Web search / web fetch tool type | `web_search_20250305`, `web_fetch_20250910` | `web_search_20260209`,
`web_fetch_20260209` (dynamic filtering) on Opus 5/4.8/4.7/4.6, Sonnet 5, and Sonnet 4.6. Older models keep
the basic variants; on Vertex AI only basic `web_search_20250305` is available (web fetch is not on Vertex)
-- see the Server Tools QR below. |
| PHP parameter names | snake_case wire names as named args (`max_tokens`) | Top-level named args are
camelCase (`maxTokens`). Nested array keys vary by feature (e.g. `'taskBudget'`, `'skillID'`,
`'mcp_server_name'`) -- copy the exact key from the documented example; do not bulk-convert. |
| Managed Agents credentials | Keep secrets host-side via custom tools (the only option before vaults
shipped) | Vault `environment_variable` credentials -- stored by Anthropic, substituted at egress, never
visible in the sandbox (`shared/managed-agents-tools.md` -> Vaults). Host-side custom tools remain the
fallback for self-hosted sandboxes. |

The `{lang}/` files in this skill are authoritative over recalled patterns.

---

## Subcommands

If the User Request at the bottom of this prompt is a bare subcommand string (no prose), search every
**Subcommands** table in this document -- including any in sections appended below -- and follow the matching
Action column directly. This lets users invoke specific flows via `/claude-api <subcommand>`. If no table in
the document matches, treat the request as normal prose.
```

```
| Subcommand | Action |
|---|---|
| `migrate` | Migrate existing Claude API code to a newer model. **Read `shared/model-migration.md` immediately** and follow it in order: Step 0 (confirm scope -- ask which files/directories before any edit), Step 1 (classify each file), then the per-target breaking-changes section. Do not summarize the guide -- execute it. If the user did not name a target model, ask which model to migrate to in the same turn as the scope question. After the per-target changes are applied, audit the in-scope prompt text, tool descriptions, and request code against `shared/prompt-audit.md` -- prompting written for the source model is part of every migration, and it does not announce itself. |
| `prompt-audit` | Audit existing prompts, skills, and tool descriptions for dated patterns ("cruft") written for older models. **Read `shared/prompt-audit.md` immediately** and follow it in order: Step 0 (establish scope and target model from the request and the repository -- state the assumptions in the report, do not stop to ask), inventory, provenance, then the pattern scan. Produce both deliverables in full -- the audit report (findings with `file:line`, pattern, why it's obsolete for the target model, confidence) and a proposed diff -- without pausing for confirmation; apply edits only if the request explicitly asked for them. Do not summarize the guide -- execute it. |

---

## Language Detection

Before reading code examples, determine which language the user is working in (exception: for the `prompt-audit` subcommand, skip this section's ask steps -- the audit is non-interactive and its inventory is language-agnostic; when no language is inferable, proceed without asking and state the assumption in the report):

1. **Look at project files** to infer the language:

   - `*.py`, `requirements.txt`, `pyproject.toml`, `setup.py`, `Pipfile` -> **Python** -- read from `python/`
   - `*.ts`, `*.tsx`, `package.json`, `tsconfig.json` -> **TypeScript** -- read from `typescript/`
   - `*.js`, `*.jsx` (no `.ts` files present) -> **TypeScript** -- JS uses the same SDK, read from `typescript/`
   - `*.java`, `pom.xml`, `build.gradle` -> **Java** -- read from `java/`
   - `*.kt`, `*.kts`, `build.gradle.kts` -> **Java** -- Kotlin uses the Java SDK, read from `java/`
   - `*.scala`, `build.sbt` -> **Java** -- Scala uses the Java SDK, read from `java/`
   - `*.go`, `go.mod` -> **Go** -- read from `go/`
   - `*.rb`, `Gemfile` -> **Ruby** -- read from `ruby/`
   - `*.cs`, `*.csproj` -> **C#** -- read from `csharp/`
   - `*.php`, `composer.json` -> **PHP** -- read from `php/`

2. **If multiple languages detected** (e.g., both Python and TypeScript files):

   - Check which language the user's current file or question relates to
   - If still ambiguous, ask: "I detected both Python and TypeScript files. Which language are you using for the Claude API integration?"

3. **If language can't be inferred** (empty project, no source files, or unsupported language):

   - Use AskUserQuestion with options: Python, TypeScript, Java, Go, Ruby, cURL/raw HTTP, C#, PHP
   - If AskUserQuestion is unavailable, default to Python examples and note: "Showing Python examples. Let me know if you need a different language."

4. **If unsupported language detected** (Rust, Swift, C++, Elixir, etc.):

   - Suggest cURL/raw HTTP examples from `curl/` and note that community SDKs may exist
   - Offer to show Python or TypeScript examples as reference implementations

5. **If user needs cURL/raw HTTP examples**, read from `curl/`.

### Language-Specific Feature Support

Every SDK language above supports both the beta Tool Runner and Managed Agents (beta) -- Python (`@beta_tool` decorator), TypeScript (`betaZodTool` + Zod), Java (annotated classes), Go (`BetaToolRunner` in the `toolrunner` pkg), Ruby (`BaseTool` + `tool_runner`), C# (`BetaToolRunner` + raw JSON schema), PHP (`BetaRunnableTool` + `toolRunner()`); code entry points are in the Tool Use Patterns quick reference below. cURL is raw HTTP (no SDK features) and supports Managed Agents.

> **Managed Agents code examples**: see the reading guide in the `## Managed Agents (Beta)` section below.
```

```
---

## Which Surface Should I Use?

> **Start simple.** Default to the simplest tier that meets your needs. Single API calls and workflows handle
most use cases -- only reach for agents when the task genuinely requires open-ended, model-driven
exploration. "Simplest" means the least code you own: for a hosted, scheduled, or memory-backed agent,
Managed Agents is usually the simplest option (no loop code, no state files, no scheduler), even though it's
a bigger platform.

| Use Case                                        | Tier            | Recommended Surface       | Why
|
| ----------------------------------------------- | --------------- | ------------------------- |
---------------------------------------------------------- |
| Classification, summarization, extraction, Q&A  | Single LLM call | **Claude API**            | One
request, one response                                 |
| Batch processing or embeddings                  | Single LLM call | **Claude API**            | Specialized
endpoints                                            |
| Multi-step pipelines with code-controlled logic | Workflow        | **Claude API + tool use** | You
orchestrate the loop                                  |
| Custom agent with your own tools                | Agent           | **Claude API + tool use** | Maximum
flexibility                                             |
| Server-managed stateful agent with workspace    | Agent           | **Managed Agents**        | Anthropic
runs the loop and hosts the tool-execution sandbox |
| Persisted, versioned agent configs              | Agent           | **Managed Agents**        | Agents are
stored objects; sessions pin to a version         |
| Long-running multi-turn agent with file mounts  | Agent           | **Managed Agents**        | Per-session
containers, SSE event stream, Skills + MCP       |
| Agent that runs on a schedule (cron, "every night") | Agent       | **Managed Agents** -- scheduled
deployments | Deployments fire sessions autonomously; no client-side scheduler |

> **Note:** Managed Agents is the right choice when you want Anthropic to run the agent loop *and* host the
container where tools execute -- file ops, bash, code execution all run in the per-session workspace. If you
want to host the compute yourself or run your own custom tool runtime, Claude API + tool use is the right
choice -- use the tool runner for the agentic loop -- its per-turn hooks still give you approval gates,
logging, error interception, and conditional execution (see `shared/tool-use-concepts.md`) -- or the manual
loop when you want to own the entire loop yourself.

> **Cloud-provider access.** **Claude Platform on AWS** is Anthropic-operated with same-day API parity -- see
`shared/claude-platform-on-aws.md` for client setup. For per-feature availability on **Claude Platform on
AWS**, **Amazon Bedrock**, **Google Vertex AI**, and **Microsoft Foundry**, see
`shared/platform-availability.md` -- that table is the single source of truth in this skill; do not infer
availability from anywhere else.

### Building an Agent: Four Approaches

Once you've decided you actually need an agent (open-ended, model-driven tool use), there are four distinct
ways to build one. Two independent questions separate them: **who supplies the harness** (the agent loop +
context management) and **who supplies the deployment** (the infra the agent runs on). The Tool Runner and
the Claude Agent SDK both supply a *harness only* -- you still host and deploy them yourself -- which is why
they're easy to conflate. Managed Agents (CMA) is the only option that supplies **both** the harness *and*
managed deployment; the manual loop supplies neither.

| # | Approach | You write | Harness & deployment | Tools available | Use when |
|---|----------|-----------|----------------------|-----------------|----------|
| 1 | **Claude API -- manual loop** | The `while stop_reason == "tool_use"` loop yourself | You build the
harness; you host | Only tools you define | You want to own the *entire* loop -- no beta dependency, or a
control flow the Tool Runner's per-turn hooks don't fit |
| 2 | **Claude API -- Tool Runner** (`client.beta.messages.tool_runner` + `@beta_tool` / `betaZodTool`) |
Just the tool functions | SDK supplies the loop (**harness only**); you host | Only tools you define | A
custom-tool agent without hand-writing the loop (most cases). Per-turn hooks still give you approval gates,
error interception, result modification (e.g. `cache_control`), retries, streaming, and compaction |
| 3 | **Managed Agents** (REST, beta) | Agent config + your tool results | Anthropic supplies the harness
**and** hosts a per-session sandbox (**harness + deployment**) | Anthropic-hosted sandbox (bash, files, code
exec) + Skills/MCP + your tools | You want Anthropic to run the loop *and* host the per-session workspace;
persisted/versioned configs; long-running sessions |
| 4 | **Claude Agent SDK** -- *separate product* (`claude-agent-sdk` / `@anthropic-ai/claude-agent-sdk`) | A
prompt + options | SDK supplies the Claude Code harness + built-in tools (**harness only**); you host |
Built-in Read/Write/Edit/Bash/Glob/Grep/WebSearch/WebFetch + MCP + subagents | You want a batteries-included
coding/filesystem agent running on your own infra |
```

```
The harness/deployment split is the key mental model: options 1, 2, and 4 all **leave deployment to you**;
only option 3 (CMA) adds managed deployment. Options 1-3 are what this skill generates; option 4 is a
different library with its own docs -- see the disambiguation below.

> **Tool Runner != Claude Agent SDK.** These sound alike but are different packages:
> - **Tool Runner** is part of the regular Anthropic API SDK (`anthropic` / `@anthropic-ai/sdk`), reached via
`client.beta.messages.tool_runner`. It automates the request -> execute -> loop cycle *for tools you define*.
No built-in tools, no filesystem access, no sandbox -- you supply every tool and host the compute. It is
option 2 above, a thin helper over `POST /v1/messages`.
> - **Claude Agent SDK** (`claude-agent-sdk` / `@anthropic-ai/claude-agent-sdk`) is Claude Code packaged as a
library. It ships built-in tools (file read/write/edit, bash, grep, web search), the full agent loop, context
management, hooks, subagents, permissions, and sessions. You call `query(prompt, options)` and it drives
everything.
>
> Both are **harness-only -- you host and deploy them.** The difference is scope of harness: the Tool Runner
loops over tools *you* define (with per-turn hooks for approval, interception, result modification, and
retries -- but no built-in tools); the Agent SDK is the full Claude Code harness with built-in tools. Neither
provides managed deployment -- that's what **Managed Agents (CMA)** adds (Anthropic hosts the loop and a
per-session sandbox).
>
> **This skill covers the Claude API and Managed Agents (options 1-3); it does not generate Claude Agent SDK
code.** If the user actually wants the Claude Agent SDK, point them to its docs
(`code.claude.com/docs/en/agent-sdk`) -- don't substitute the API Tool Runner for it, or vice-versa.

### Should I Build an Agent?

Before choosing the agent tier, check all four criteria:

- **Complexity** -- Is the task multi-step and hard to fully specify in advance? (e.g., "turn this design doc
into a PR" vs. "extract the title from this PDF")
- **Value** -- Does the outcome justify higher cost and latency?
- **Viability** -- Is Claude capable at this task type?
- **Cost of error** -- Can errors be caught and recovered from? (tests, review, rollback)

If the answer is "no" to any of these, stay at a simpler tier (single call or workflow).

---

## Architecture

Everything goes through `POST /v1/messages`. Tools and output constraints are features of this single
endpoint -- not separate APIs.

**User-defined tools** -- You define tools (via decorators, Zod schemas, or raw JSON), and the SDK's tool
runner handles calling the API, executing your functions, and looping until Claude is done. For full control,
you can write the loop manually.

**Server-side tools** -- Anthropic-hosted tools that run on Anthropic's infrastructure. Code execution is
fully server-side (declare it in `tools`, Claude runs code automatically). Computer use can be server-hosted
or self-hosted.

**Structured outputs** -- Constrains the Messages API response format (`output_config.format`) and/or tool
parameter validation (`strict: true`). The recommended approach is `client.messages.parse()` which validates
responses against your schema automatically. Note: the old `output_format` parameter is deprecated; use
`output_config: {format: {...}}` on `messages.create()`.

**Supporting endpoints** -- Batches (`POST /v1/messages/batches`), Files (`POST /v1/files`), Token Counting
(`POST /v1/messages/count_tokens` -- see `shared/token-counting.md`), and Models (`GET /v1/models`, `GET
/v1/models/{id}` -- live capability/context-window discovery) feed into or support Messages API requests.

---

## Current Models (cached: 2026-06-24)

| Model             | Model ID            | Context        | Input $/1M | Output $/1M |
| ----------------- | ------------------- | -------------- | ---------- | ----------- |
| Claude Fable 5    | `claude-fable-5`      | 1M             | $10.00     | $50.00      |
| Claude Mythos 5 (Project Glasswing only) | `claude-mythos-5` | 1M | $10.00     | $50.00      |
| Claude Opus 5     | `claude-opus-5`       | 1M             | $5.00      | $25.00      |
```

```
| Claude Opus 4.8 | `claude-opus-4-8`  | 1M             | $5.00      | $25.00      |
| Claude Opus 4.7   | `claude-opus-4-7`   | 1M             | $5.00      | $25.00      |
| Claude Opus 4.6   | `claude-opus-4-6`   | 1M             | $5.00      | $25.00      |
| Claude Sonnet 5   | `claude-sonnet-5`   | 1M             | $3.00 ($2.00 intro through 2026-08-31) | $15.00
($10.00 intro) |
| Claude Sonnet 4.6 | `claude-sonnet-4-6` | 1M             | $3.00      | $15.00      |
| Claude Haiku 4.5  | `claude-haiku-4-5`  | 200K           | $1.00      | $5.00       |

**Partner pricing:** The prices above are Anthropic first-party API rates -- they also apply to Claude on
Microsoft Foundry, which is billed through the Microsoft Marketplace at standard API rates. Claude on Amazon
Bedrock and Vertex AI is partner-operated with separate pricing -- see
[Bedrock](https://aws.amazon.com/bedrock/pricing/) or [Vertex
AI](https://cloud.google.com/vertex-ai/generative-ai/pricing#claude-models). For WebFetch, use the Pricing
row in `shared/live-sources.md`.

**ALWAYS use `claude-opus-5` unless the user explicitly names a different model.** This is non-negotiable. Do
not use `claude-sonnet-5`, `claude-sonnet-4-6`, or any other model unless the user literally says "use
sonnet" or "use haiku". Never downgrade for cost -- that's the user's decision, not yours. Use
`claude-fable-5` only when the user explicitly asks for Claude Fable 5, "fable", or Anthropic's most capable
model -- it has different API behavior than the Opus family (see below) and pricing that exceeds Opus-tier.
**Use only the exact model ID strings from the table -- they are complete as-is; never append date suffixes**
(`claude-sonnet-4-6`, never `claude-sonnet-4-6-20251114` or any other date-suffixed variant you might recall
from training data). If the user requests an older model not in the table (e.g., "opus 4.5", "sonnet 3.7"),
read `shared/models.md` for the exact ID -- do not construct one yourself.

### Claude Fable 5 (`claude-fable-5`) -- most capable widely released model

Claude Fable 5 is Anthropic's most capable widely released model, for the most demanding reasoning and
long-horizon agentic work; everything below also applies to **Claude Mythos 5** (`claude-mythos-5`, Project
Glasswing -- same capabilities, pricing, and API surface; successor to the invitation-only
`claude-mythos-preview`). 1M context window (the maximum is also the default), 128K max output. Key API
differences from Opus-tier -- see `shared/model-migration.md` -> Migrating to Claude Fable 5 for details:

- **Thinking is always on** -- omit the `thinking` parameter entirely (or send `{type: "adaptive"}`). Any
other explicit configuration is rejected: `{type: "disabled"}` and `{type: "enabled", budget_tokens: N}` both
return a 400. Control depth with `output_config.effort` (supports `low` through `xhigh` and `max`).
- **The raw chain of thought is never returned** -- responses carry regular `thinking` blocks (not
`redacted_thinking`): `display: "summarized"` returns a readable summary, `"omitted"` (the default) leaves
the `thinking` field as an empty string. Replay rules: pass thinking blocks back unchanged on the same model;
other models drop them silently (unbilled -- nothing to strip); details in `shared/model-migration.md`.
- **Tokenizer** -- same tokenizer as Opus 4.8 (introduced with Opus 4.7). Token counts are roughly unchanged
when migrating from Opus 4.7/4.8; per-token pricing differs. Coming from Opus 4.6, Sonnet, Haiku, or older,
re-baseline with `count_tokens` (the Opus 4.7 tokenizer uses ~1x-1.35x as many tokens).
- **`refusal` stop reason -- handle it, and opt into fallbacks by default** -- safety classifiers may decline
a request (HTTP 200, `stop_reason: "refusal"`, with a `stop_details` category); always check `stop_reason`
before reading `content`. **When you write `claude-fable-5` or `claude-opus-5` code, include the server-side
`fallbacks` parameter by default.** Simplest form: `betas: ["server-side-fallback-2026-07-01"]` + `fallbacks:
"default"`, which routes by refusal category so you never maintain a model list. (The older array form --
`betas: ["server-side-fallback-2026-06-01"]` + `fallbacks: [{"model": "claude-opus-4-8"}]` -- still works;
Claude API only -- everywhere else, incl. Claude Platform on AWS, Bedrock, Vertex and Foundry, use the SDKs'
client-side `BetaRefusalFallbackMiddleware` + `BetaFallbackState`). Tell the user you've enabled it; drop it
only if they decline. Full semantics (billing, mid-stream refusals, credit repricing) in
`shared/model-migration.md` -> refusal section. **Per-language code examples in `{lang}/claude-api/README.md`
? Refusal Fallbacks cover the array form only** -- for the `"default"` mode, follow the raw-HTTP shape in
`shared/model-migration.md` -> Migrating to Claude Opus 5 -> New API features and swap `fallbacks: [{...}]`
for `fallbacks: "default"` plus the `-2026-07-01` header; the rest of the request is unchanged.
- **No assistant prefill** -- same as the rest of the 4.6+ family.
- **30-day data retention required** -- Claude Fable 5 is not available under zero data retention; requests
from an org whose retention configuration doesn't meet the requirement return `400 invalid_request_error`.
- **Longer turns, different prompting** -- single requests on hard tasks can run many minutes (plan
timeouts/streaming/progress UX); effort sweeps should include low/medium for routine work; prompts written
for prior models are often too prescriptive and reduce output quality. See `shared/model-migration.md` ->
Migrating to Claude Fable 5 -> Behavioral shifts (prompt-tunable) for the recommended prompt snippets.

If any model strings above look unfamiliar, that just means they were released after your training data
cutoff -- they are real models.

**Live capability lookup:** The table above is cached. When the user asks "what's the context window for X",
"does X support vision/thinking/effort", or "which models support Y", query the Models API
(`client.models.retrieve(id)` / `client.models.list()`) -- see `shared/models.md` for the field reference and
```

```
capability-filter examples.

---

## Authentication (Quick Reference)

**An unset `ANTHROPIC_API_KEY` does NOT mean there are no credentials.** The SDKs and the `ant` CLI resolve credentials in this order (first match wins): `ANTHROPIC_API_KEY` -> `ANTHROPIC_AUTH_TOKEN` -> the `ANTHROPIC_PROFILE`-selected or active OAuth profile from `ant auth login` -> Workload Identity Federation env vars -> the default profile on disk. A bare `Anthropic()` / `new Anthropic()` / `anthropic.NewClient()` works after `ant auth login` with no env var set.

**When you need to call the API and `ANTHROPIC_API_KEY` is unset, don't ask the user for a key.** First run `ant auth status` -- it shows which credential source and profile is active. If it reports an active profile:

- **SDK code or `ant` CLI:** just run it. The zero-arg client constructor and every `ant ...` subcommand pick up the profile automatically -- no env var needed.
- **Raw `curl` / HTTP:** get a short-lived token with `ant auth print-credentials --access-token` and send it as `Authorization: Bearer <token>` **plus** the header `anthropic-beta: oauth-2025-04-20` (OAuth tokens go on `Authorization: Bearer`, not `x-api-key:` -- converting a curl from an API key is a header change, not a key swap). Always pass `--access-token`; the no-flag form prints JSON, not a bare token.

Only ask the user for a key if `ant auth status` reports no active credential source (or `ant` itself isn't installed). Suggest `ant auth login` as the first option -- it stores a profile under `~/.config/anthropic/` that the SDKs read automatically -- and an exported `ANTHROPIC_API_KEY` as the alternative.

Full auth details (named profiles, scopes, the API-key-shadows-profile trap, refresh-token expiry): `shared/anthropic-cli.md`.

---

## Thinking & Effort (Quick Reference)

Use adaptive thinking (`thinking: {type: "adaptive"}`) on every current model -- Claude dynamically decides when and how much to think. Per-model rules:

| Model | Thinking config | Omitting `thinking` | `budget_tokens` | Sampling (`temperature`/`top_p`/`top_k`) | Effort levels |
|---|---|---|---|---|---|
| Fable 5 | `{type: "adaptive"}` or omit; explicit `{type: "disabled"}` returns 400 -- omit the param instead | Runs adaptive (thinking is always on) | Removed -- `{type: "enabled", budget_tokens: N}` returns 400 | Removed -- 400 | `low`/`medium`/`high`/`xhigh`/`max` |
| Claude Opus 5 | `{type: "adaptive"}` or omit; `{type: "disabled"}` accepted **only at effort `high` or below** -- 400 at `xhigh`/`max`, and see the disabled-thinking pitfall below | Runs **adaptive** (thinking is on by default -- unlike Opus 4.8/4.7) | Removed -- 400 | Removed -- 400 | `low`-`max` (all five) |
| Opus 4.8 / 4.7 | `{type: "adaptive"}` is the only on-mode; `{type: "disabled"}` accepted | Runs **without** thinking -- set `{type: "adaptive"}` explicitly | Removed -- 400 | Removed -- 400 | `low`/`medium`/`high`/`xhigh`/`max` |
| Sonnet 5 | `{type: "adaptive"}` is the only on-mode; `{type: "disabled"}` accepted | Runs adaptive | Removed -- 400 | Removed -- 400 | `low`/`medium`/`high`/`xhigh`/`max` |
| Opus 4.6 / Sonnet 4.6 | `{type: "adaptive"}` (recommended; auto-enables interleaved thinking, no beta header) | Set `{type: "adaptive"}` explicitly | Deprecated -- do not use in new code; transitional escape hatch only (see below) | Allowed | `low`/`medium`/`high`/`max` (`xhigh` arrived with Opus 4.7) |
| Older (Sonnet 4.5, Haiku 4.5, ...) | -- only if explicitly requested | `{type: "enabled", budget_tokens: N}` | No thinking | Required for thinking; must be less than `max_tokens`, minimum 1024 -- errors otherwise | Allowed | `effort` works on Opus 4.5 (`low`/`medium`/`high` only -- no `xhigh`/`max`); errors on Sonnet 4.5 / Haiku 4.5 |

Opus 4.8 keeps the same request surface as 4.7 (no new breaking changes) -- see `shared/model-migration.md` -> Migrating to Opus 4.8 for the behavioral re-tuning, and -> Migrating to Opus 4.7 for the full breaking-change list when coming from 4.6 or earlier. With `thinking` disabled, Opus 4.8 may write longer reasoning into the visible response -- leave adaptive thinking on, or add a final-answer-only instruction (see the migration guide).

- **Effort (GA, no beta header):** `output_config: {effort: "low"|"medium"|"high"|"xhigh"|"max"}` -- inside `output_config`, not top-level; default `high` (equivalent to omitting it). Controls thinking depth and overall token spend; combine with adaptive thinking for the best cost-quality tradeoffs. `xhigh` (added on Opus 4.7, between `high` and `max`) is the best setting for most coding and agentic use cases on Fable 5 / Opus 4.7/4.8 / Sonnet 5, and the default in Claude Code; effort matters more on those models than on any prior model in their tier -- re-tune it when migrating, and run long-horizon/agentic tasks at `high`/`xhigh`
```

```
with the full task spec given up front. Use a minimum of `high` for intelligence-sensitive work, `max` when
correctness matters more than cost, and `low` for subagents or simple tasks -- lower effort means fewer and
more-consolidated tool calls, less preamble, and terser confirmations (`high` is often the sweet spot
balancing quality and token efficiency).
- **Thinking display -- `"omitted"` by default on Fable 5 / Mythos 5 / Opus 5 / 4.8 / 4.7 / Sonnet 5:**
`display: "summarized"` returns a readable summary of the reasoning; `"omitted"` (the default on all six -- a
silent change from Opus 4.6 and Sonnet 4.6, where it was `"summarized"`) streams `thinking` blocks with empty
text. `display` controls visibility only -- thinking happens and is billed the same under every setting; the
raw chain of thought is never exposed on any model. If you stream reasoning to users, the default looks like
a long pause before output -- set `thinking: {type: "adaptive", display: "summarized"}` explicitly.
(Independent of display, echo thinking blocks back unchanged when continuing on the same model; other models
silently ignore them -- see the migration guide.)
- **When the user asks for "extended thinking", a "thinking budget", or `budget_tokens`:** always use Fable
5, Opus 5, 4.8, 4.7, or 4.6 with `thinking: {type: "adaptive"}` -- the fixed thinking-token-budget concept is
deprecated and adaptive thinking replaces it. Do NOT use `budget_tokens` for new 4.6/4.7/4.8 code and do NOT
switch to an older model just because the user mentions it. *Gradual-migration carve-out:* `budget_tokens` is
still functional on Opus 4.6 and Sonnet 4.6 only, as a transitional escape hatch for existing code that needs
a hard token ceiling before you've tuned `effort` -- see `shared/model-migration.md` -> Transitional escape
hatch. It is fully removed on Fable 5, Opus 5/4.7/4.8, and Sonnet 5.

---

## Compaction (Quick Reference)

**Beta, Fable 5, Opus 5, Opus 4.8, Opus 4.7, Opus 4.6, Sonnet 5, and Sonnet 4.6.** For long-running
conversations that may exceed the 1M context window, enable server-side compaction. The API automatically
summarizes earlier context when it approaches the trigger threshold (default: 150K tokens). Requires beta
header `compact-2026-01-12`.

**Critical:** Append `response.content` (not just the text) back to your messages on every turn. Compaction
blocks in the response must be preserved -- the API uses them to replace the compacted history on the next
request. Extracting only the text string and appending that will silently lose the compaction state.

See `{lang}/claude-api/README.md` (Compaction section) for code examples. Full docs via WebFetch in
`shared/live-sources.md`.

---

## Prompt Caching (Quick Reference)

**Prefix match.** Any byte change anywhere in the prefix invalidates everything after it. Render order is
`tools` -> `system` -> `messages`. Keep stable content first (frozen system prompt, deterministic tool list),
put volatile content (timestamps, per-request IDs, varying questions) after the last `cache_control`
breakpoint.

**Mid-conversation operator instructions** (Claude Opus 5, Claude Opus 4.8, Claude Fable 5, Claude Mythos 5;
not Claude Sonnet 5; no beta header): append `{"role": "system", ...}` to `messages[]` instead of editing
top-level `system`. Preserves the cached history prefix and is the prompt-injection-safe operator channel.
See `shared/prompt-caching.md` ? Mid-conversation system messages.

**Top-level auto-caching** (`cache_control: {type: "ephemeral"}` on `messages.create()`) is the simplest
option when you don't need fine-grained placement. Max 4 breakpoints per request. Minimum cacheable prefix is
~1024 tokens -- shorter prefixes silently won't cache.

**Verify with `usage.cache_read_input_tokens`** -- if it's zero across repeated requests, a silent
invalidator is at work (`datetime.now()` in system prompt, unsorted JSON, varying tool set).

For placement patterns, architectural guidance, and the silent-invalidator audit checklist: read
`shared/prompt-caching.md`. Language-specific syntax: `{lang}/claude-api/README.md` (Prompt Caching section).

---

## Fast Mode (Quick Reference)

**Research preview, Claude Opus 5 / Opus 4.8 only** -- Claude API and Managed Agents, not Bedrock / Google
Cloud / Foundry. Opus 4.7 fast mode has been removed: `speed: "fast"` on 4.7 returns an error. Fast mode on
Claude Opus 5 is priced at $10 / $50 per MTok. Fast mode runs the same model at up to 2.5x higher output
tokens per second, at premium pricing. Three things are required on every request: use the **beta** messages
endpoint (`client.beta.messages....`), pass the beta flag `fast-mode-2026-02-01`, and set `speed: "fast"` as
a top-level request parameter (not a header, not in `extra_body`).
```

```python
client.beta.messages.create(
    model="claude-opus-5", max_tokens=4096,
    speed="fast", betas=["fast-mode-2026-02-01"],
    messages=[...],
)
```

Language	Beta flag	Speed parameter
Python	`betas=["fast-mode-2026-02-01"]`	`speed="fast"`
TypeScript / Ruby	`betas: ["fast-mode-2026-02-01"]`	`speed: "fast"`
Go	`[]anthropic.AnthropicBeta{anthropic.AnthropicBetaFastMode2026_02_01}`	`Speed: anthropic.BetaMessageNewParamsSpeedFast`
Java	`.addBeta(AnthropicBeta.FAST_MODE_2026_02_01)`	`.speed(MessageCreateParams.Speed.FAST)`
C#	`Betas = ["fast-mode-2026-02-01"]`	`Speed = Speed.Fast` (`Anthropic.Models.Beta.Messages`)
PHP	`betas: ['fast-mode-2026-02-01']`	`speed: 'fast'`
cURL	`anthropic-beta: fast-mode-2026-02-01` header	`"speed": "fast"` in body

`response.usage.speed` reports which speed was used. Fast mode has its own rate limit separate from standard Opus; on 429, either retry after the `retry-after` delay or drop `speed` and fall back to standard (note: switching speed invalidates prompt cache). Not available with Batch API, Priority Tier, Claude Platform on AWS, or third-party platforms.

Priority Tier does not cover Claude Opus 5. It is supported on every other current model, including Claude Fable 5 and Opus 4.8, but Claude Opus 5, Claude Sonnet 5, Claude Mythos 5, and Mythos Preview are excluded -- a Priority Tier request naming one of them fails validation.

Task Budgets (Quick Reference)

Beta, Claude Opus 5 / Fable 5 / Sonnet 5 / Opus 4.8 / 4.7. A task budget gives Claude a token ceiling for an agentic loop so it paces itself and finishes gracefully instead of being cut off -- distinct from `max_tokens`, which is an enforced per-response ceiling the model is not aware of. Minimum `total`: 20,000. Set `task_budget` inside `output_config` on `client.beta.messages.stream(...)` with beta flag `task-budgets-2026-03-13` -- use streaming so the large `max_tokens` doesn't hit HTTP timeouts (full details: `shared/model-migration.md` -> Task Budgets):

```python
with client.beta.messages.stream(
    model="claude-opus-5", max_tokens=128000,
    output_config={"effort": "high", "task_budget": {"type": "tokens", "total": 64000}},
    betas=["task-budgets-2026-03-13"],
    messages=[...], tools=[...],
) as stream:
    response = stream.get_final_message()
```

`task_budget` fields: `type` (always `"tokens"`), `total`, and optional `remaining` (defaults to `total`). The server injects a countdown marker Claude sees during generation; the budget counts what Claude generates and the tool results it reads this turn -- **not** the full history you resend each request. Not the same thing as **Managed Agents session budgets** -- those are hard, dollar-denominated, platform-enforced caps on one CMA session (`shared/managed-agents-core.md` ? Session budgets); a task budget is advisory and token-denominated.

Observing spend: accumulate `response.usage.output_tokens` (plus the token count of the tool-result blocks you append) across loop iterations if you want to display progress. Leave `remaining` unset in the normal loop -- the server tracks the countdown itself, and passing a client-computed `remaining` while also resending full history under-reports the budget. **Only pass `remaining`** when you compact or rewrite history between requests and the server can no longer derive prior spend.

Provider Clients (Quick Reference)

When targeting Claude on a third-party platform, use that platform's dedicated client class -- not the first-party `Anthropic()` client with a `base_url` override. After construction the client exposes the same `messages.create` / `.stream` surface as the first-party SDK.

```
### Amazon Bedrock

Use the **Mantle** client (Messages-API Bedrock endpoint). Bedrock model IDs take an `anthropic.` prefix
(e.g. `"anthropic.claude-opus-5"`). Region is required.

| Language | Client |
|---|---|
| Python | `from anthropic import AnthropicBedrockMantle` -> `AnthropicBedrockMantle(aws_region="...")` |
| TypeScript | `import { AnthropicBedrockMantle } from "@anthropic-ai/bedrock-sdk"` -> `new
AnthropicBedrockMantle({ awsRegion: "..." })` |
| Go | `bedrock.NewMantleClient(ctx, bedrock.MantleClientConfig{ AWSRegion: "..." })` |
| Java | `AnthropicOkHttpClient.builder().backend(BedrockMantleBackend.fromEnv()).build()` (from
`com.anthropic.bedrock.backends`) |
| C# | `new AnthropicBedrockMantleClient(new() { AwsRegion = "..." })` (package `Anthropic.Bedrock`) |
| PHP | `use Anthropic\Bedrock\MantleClient;` -> `new MantleClient(awsRegion: '...')` |
| Ruby | `Anthropic::BedrockMantleClient.new(aws_region: "...")` |

`AnthropicBedrock` / `BedrockClient` / `BedrockBackend` (without `Mantle`) are the legacy `bedrock-runtime`
InvokeModel path -- prefer the Mantle client for new code.

### Microsoft Foundry

| Language | Client |
|---|---|
| Python | `from anthropic import AnthropicFoundry` -> `AnthropicFoundry(api_key=..., resource="...")` |
| TypeScript | `import AnthropicFoundry from "@anthropic-ai/foundry-sdk"` -> `new AnthropicFoundry({ ... })` |
| Java | `AnthropicOkHttpClient.builder().backend(FoundryBackend.fromEnv()).build()` (from
`com.anthropic.foundry.backends`) |
| C# | `new AnthropicFoundryClient(new AnthropicFoundryApiKeyCredentials(...))` (package `Anthropic.Foundry`)
|
| PHP | `Foundry\Client::withCredentials(...)` |

The Go and Ruby SDKs do not currently support Foundry. For Ruby, use the standard
`Anthropic::Client.new(base_url: "<foundry endpoint>")` as a fallback (Entra ID auth is not built in). For
Claude Platform on AWS, see `shared/claude-platform-on-aws.md`.

### Google Cloud Vertex AI

Two required constructor args: GCP `project_id` and `region`. Vertex model IDs take **no prefix** --
current-generation models (Opus 4.8/4.7/4.6, Sonnet 5, Sonnet 4.6) use the bare first-party ID (e.g.
`"claude-opus-5"`); dated-snapshot models use an `@` version separator (e.g. `claude-opus-4-5@20251101`,
**not** `claude-opus-4-5-20251101`). Auth is GCP ADC (`gcloud auth application-default login`); no Anthropic
API key. `region` can be `"global"` (recommended), a multi-region (`"us"`/`"eu"`), or a specific region.
After construction, use the same `messages.create` / `.stream` surface.

| Language | Client |
|---|---|
| Python | `from anthropic import AnthropicVertex` -> `AnthropicVertex(project_id="...", region="...")`
(install `"anthropic[vertex]"`) |
| TypeScript | `import { AnthropicVertex } from "@anthropic-ai/vertex-sdk"` -> `new AnthropicVertex({
projectId, region })` |
| Go | `import "github.com/anthropics/anthropic-sdk-go/vertex"` ->
`anthropic.NewClient(vertex.WithGoogleAuth(ctx, region, projectID))` |
| Java |
`AnthropicOkHttpClient.builder().backend(VertexBackend.builder().region("...").project("...").build()).build()
` (from `com.anthropic.vertex.backends`) |
| C# | `new AnthropicClient { Backend = new VertexBackend(projectId, region) }` (package `Anthropic.Vertex`) |
| PHP | `use Anthropic\Vertex;` -> `Vertex\Client::fromEnvironment(location: '...', projectId: '...')` --
note `location`, not `region` |
| Ruby | `Anthropic::VertexClient.new(region: "...", project_id: "...")` |

---

## Context Editing (Quick Reference)

**Beta.** Context editing **clears** old tool results or thinking blocks from the conversation before the
model sees it; it is **not compaction** (which summarizes). On `client.beta.messages.*` with beta
`context-management-2025-06-27`, pass `context_management.edits` with a strategy type:
```

```python
client.beta.messages.create(
    model="claude-opus-5", max_tokens=4096,
    betas=["context-management-2025-06-27"],
    context_management={"edits": [{"type": "clear_tool_uses_20250919"}]},
    tools=[...], messages=[...],
)
```

Strategy types: `clear_tool_uses_20250919` (clears old tool results; optional `clear_tool_inputs: true` also clears the tool_use params) and `clear_thinking_20251015` (clears thinking blocks). Do **not** use `compact_20260112` or beta `compact-2026-01-12` -- those are the separate compaction feature.

Mid-Conversation System Messages (Quick Reference)

Claude Opus 5, Claude Opus 4.8, Claude Fable 5, and Claude Mythos 5; not Claude Sonnet 5; no beta header. Append `{"role": "system", "content": "..."}` to the `messages` array (not the top-level `system` field) to add an operator instruction mid-conversation without invalidating the cached prefix. Use the regular `client.messages.create` -- there is no beta. A mid-conversation system message must follow a `user` message (or an `assistant` message ending in server-tool use), and must be either the last entry in `messages` or be followed by an `assistant` turn -- it cannot be `messages[0]`. Availability: `shared/platform-availability.md`. See `shared/prompt-caching.md` ? Mid-conversation system messages.

Managed Agents (Beta)

Managed Agents is a third surface: server-managed stateful agents with Anthropic-hosted tool execution. You create a persisted, versioned Agent config (`POST /v1/agents`), then start Sessions that reference it. Each session provisions a container as the agent's workspace -- bash, file ops, and code execution run there; the agent loop itself runs on Anthropic's orchestration layer and acts on the container via tools. The session streams events; you send messages and tool results back.

Availability: `shared/platform-availability.md`. For agents on Bedrock / Vertex / Foundry (where Managed Agents is unsupported), use Claude API + tool use.

Mandatory flow: Agent (once) -> Session (every run). `model`/`system`/`tools` live on the agent, never the session. See `shared/managed-agents-overview.md` for the full reading guide, beta headers, and pitfalls.

Beta headers: `managed-agents-2026-04-01` -- the SDK sets this automatically for all `client.beta.{agents,environments,sessions,vaults,memory_stores,deployments,deployment_runs}.*` calls. Skills API uses `skills-2025-10-02` and Files API uses `files-api-2025-04-14`, but you don't need to explicitly pass those in for endpoints other than `/v1/skills` and `/v1/files`.

Subcommands -- invoke directly with `/claude-api <subcommand>`:

Subcommand	Action
`managed-agents-onboard`	Walk the user through setting up a Managed Agent from scratch. **Read `shared/managed-agents-onboarding.md` immediately** and follow its interview script: **describe -> configure the agent (propose, don't interrogate) -> environment -> session** (same arc as the Console quickstart, auth deferred to the session step) -- defaults and inline suggestions do the work, with a silent viability gate (job vs tools/credentials/data) before any code is emitted. Do not summarize -- run the interview.

Reading guide: Start with `shared/managed-agents-overview.md`, then the topical `shared/managed-agents-*.md` files (core, environments, tools, events, outcomes, multiagent, webhooks, memory, scheduled-deployments, client-patterns, onboarding, api-reference). For Python, TypeScript, Go, Ruby, PHP, and Java, read `{lang}/managed-agents/README.md` for code examples. For cURL, read `curl/managed-agents.md`. **Agents are persistent -- create once, reference by ID.** Define agents and environments as version-controlled YAML applied with the `ant` CLI -- this is the recommended flow (see `shared/anthropic-cli.md`): the CLI owns the control plane (creating and updating agents), your code owns the data plane (`sessions.create` with the stored agent ID). Call `agents.create()` in code only when you must provision programmatically; either way, store the returned agent ID and pass it to every subsequent `sessions.create`; never call `agents.create()` in the request path. If a binding you need isn't shown in the language README, WebFetch the relevant entry from `shared/live-sources.md` rather than guess. C# has beta Managed Agents support via `client.Beta.Agents` and related namespaces -- see `csharp/claude-api/README.md` for details, or `curl/managed-agents.md` for raw HTTP reference.

```
**When the user wants to set up a Managed Agent from scratch** (e.g. "how do I get started", "walk me through
creating one", "set up a new agent"): read `shared/managed-agents-onboarding.md` and run its interview --
same flow as the `managed-agents-onboard` subcommand.

**When the user asks "how do I write the client code for X":** reach for
`shared/managed-agents-client-patterns.md` -- covers lossless stream reconnect, `processed_at`
queued/processed gate, interrupt, `tool_confirmation` round-trip, the correct idle/terminated break gate,
post-idle status race, stream-first ordering, file-mount gotchas, etc. For credentials, lead with vault
`environment_variable` credentials -- the first-class mechanism; secrets are substituted at egress and never
enter the sandbox (`shared/managed-agents-tools.md` -> Vaults). Keeping credentials host-side via custom
tools is the fallback where vault credentials don't fit (e.g. self-hosted sandboxes).

**When the user wants the agent to run on a schedule** (cron, "every night", "weekly report"): read
`shared/managed-agents-scheduled-deployments.md` -- deployments fire sessions autonomously on a cron cadence,
with per-firing run records and lifecycle controls (pause/unpause/archive).

**When the agent's work fans out** (research across several sources, per-file or per-record work, "look into
N things, then summarize") **or one loop would fill its context with reading:** read
`shared/managed-agents-multiagent.md` and recommend a multiagent session -- start with just `{"type":
"self"}` in the roster so the agent can delegate to copies of itself, then move reading-heavy sub-tasks to a
cheaper worker agent (e.g. Claude Haiku 4.5) referenced by ID.

---

## Server Tools (Quick Reference)

Server-side tools run on Anthropic's infrastructure -- no client-side execution loop. Declare in `tools`;
results arrive as content blocks in the same response. **No beta header** unless noted. **Prefer the latest
type variant your model supports.** The `_20260209` web search / web fetch variants below (dynamic filtering)
require Opus 5/4.8/4.7/4.6, Sonnet 5, or Sonnet 4.6; the basic variants for older models are listed after the
table.

| Tool | `type` | `name` | Key optional params | Result block type |
|---|---|---|---|---|
| Web search | `web_search_20260209` | `web_search` | `max_uses`, `allowed_domains`/`blocked_domains`,
`user_location` | `web_search_tool_result` -> `.content` is a list of `web_search_result` |
| Web fetch | `web_fetch_20260209` | `web_fetch` | `max_uses`, `allowed_domains`/`blocked_domains`,
`citations`, `max_content_tokens` | `web_fetch_tool_result` -> `.content` is a `web_fetch_result` with a
`document` block |
| Code execution | `code_execution_20260521` | `code_execution` | none | `bash_code_execution_tool_result` ->
`.content.stdout` / `.stderr` / `.return_code` |
| Tool search (regex) | `tool_search_tool_regex_20251119` | `tool_search_tool_regex` | mark other tools
`defer_loading: true` | `tool_search_tool_result` |
| Tool search (BM25) | `tool_search_tool_bm25_20251119` | `tool_search_tool_bm25` | mark other tools
`defer_loading: true` | `tool_search_tool_result` |

`web_search_20260209` / `web_fetch_20260209` have built-in dynamic filtering -- code execution runs under the
hood, so do **not** separately declare `code_execution` in `tools` (a second execution environment confuses
the model). For models older than Opus 4.6 / Sonnet 4.6, use the basic variants `web_search_20250305` /
`web_fetch_20250910` instead; on Vertex AI only basic `web_search_20250305` is available.
`code_execution_20260120` (REPL persistence + programmatic tool calling) runs on Opus 4.5+ / Sonnet 4.5+.
**Go SDK only**: `code_execution_20260521` lives under `client.Beta.Messages.New` with `Betas:
[]anthropic.AnthropicBeta{"code-execution-2025-08-25"}` (other languages use plain `client.messages.create`);
`code_execution_20260120` uses the non-beta `client.Messages.New` in Go like everywhere else. Web fetch only
fetches URLs already present in the conversation. Provider availability varies by tool -- see
`shared/platform-availability.md`. See `shared/tool-use-concepts.md` for `pause_turn` handling.

## Document & File Input (Quick Reference)

**PDF (base64, no beta):** `{"type": "document", "source": {"type": "base64", "media_type":
"application/pdf", "data": <b64 string>}}` in user content, placed before the text block. Base64 string must
have no newlines. Limits: 32 MB request, 600 pages (100 for 200k-context models). Java:
`ContentBlockParam.ofDocument(DocumentBlockParam... Base64PdfSource.builder().data(...))`.

**Files API (beta `files-api-2025-04-14`):** upload via `client.beta.files.upload(...)` -> response `id` is
the `file_id`. Reference it as `{"type": "document", "source": {"type": "file", "file_id": "..."}}` for
PDF/text, or `{"type": "image", ...}` for images -- the content-block type must match the file's MIME type.
The beta header is required on **both** the upload and the `messages.create` that references the file.
Availability: `shared/platform-availability.md`.
```

```
**Citations (no beta):** set `citations: {enabled: true}` on each `document` content block (all or none).
Response splits into multiple `text` blocks; cited blocks carry a `citations` array. Each citation has
`cited_text`, `document_index`, `document_title`, and a location by `type`: `char_location`
(`start_char_index`/`end_char_index`) for plain text, `page_location` (`start_page_number`/`end_page_number`,
1-indexed) for PDF, `content_block_location` for custom content. Incompatible with `output_config.format`
(returns a 400).

## Tool Use Patterns (Quick Reference)

**Strict tool use (no beta):** set `strict: true` as a top-level field on the tool definition (alongside
`name`/`description`/`input_schema`), **not** on `tool_choice`. Schema must have `additionalProperties:
false` + `required`. Guarantees `tool_use.input` validates exactly. Go: `Strict: anthropic.Bool(true)` +
`additionalProperties` via `InputSchema.ExtraFields`; Java: `.strict(true)` +
`.putAdditionalProperty("additionalProperties", JsonValue.from(false))`.

**Parallel tool use (default on):** one assistant message may contain multiple `tool_use` blocks. Execute
them concurrently, then return **all** `tool_result` blocks in a **single** user message -- splitting them
across multiple messages silently trains Claude to stop making parallel calls. For a failed tool, return
`tool_result` with `is_error: true` -- don't drop it.

**Tool Runner (SDK beta helper):** drives the tool-call loop for you via `client.beta.messages.*`. Python:
`@beta_tool` decorator + `client.beta.messages.tool_runner(...)` -> `runner.until_done()`. TypeScript:
`betaZodTool({...})` from `@anthropic-ai/sdk/helpers/beta/zod` + `client.beta.messages.toolRunner(...)` ->
`await runner`. Go: `toolrunner.NewBetaToolFromJSONSchema(...)` + `client.Beta.Messages.NewToolRunner(...)`
-> `.RunToCompletion(ctx)`. Java requires `.addBeta("structured-outputs-2025-11-13")`. Ruby:
`Anthropic::BaseTool` subclass + `client.beta.messages.tool_runner(...)`. PHP: `BetaRunnableTool` +
`->toolRunner(...)`. C#: raw JSON-schema tools + `BetaToolRunner` via `client.Beta.Messages.ToolRunner(...)`.

**Programmatic tool calling (no beta header):** Claude calls your custom tool from inside code execution. Add
`{"type": "code_execution_20260120", "name": "code_execution"}` **and** set `"allowed_callers":
["code_execution_20260120"]` on your custom tool. Opus 4.5+ / Sonnet 4.5+ (availability:
`shared/platform-availability.md`). When responding to a pending programmatic call, the user message must
contain **only** `tool_result` blocks (no text). Not compatible with `strict: true`,
`disable_parallel_tool_use`, forced `tool_choice`, or MCP tools.

## Other API Surfaces (Quick Reference)

**Message Batches (no beta; availability: `shared/platform-availability.md`):**
`client.messages.batches.create(requests=[{custom_id, params}, ...])` -> poll
`client.messages.batches.retrieve(id).processing_status` until `"ended"` -> stream
`client.messages.batches.results(id)`. Each result has `.custom_id` + `.result.type`
(`succeeded`/`errored`/`canceled`/`expired`); on success read `.result.message.content`. Python wraps
requests as `Request(custom_id=..., params=MessageCreateParamsNonStreaming(...))`. Results arrive in **any
order** -- key by `custom_id`, never by position.

**Models API (no beta; availability: `shared/platform-availability.md`):** `client.models.list()`
(auto-paginates) and `client.models.retrieve("claude-opus-5")`. Each model object has `id`, `display_name`,
`created_at`, and -- since Mar 2026 -- `max_input_tokens` (the context window), `max_tokens` (the output
cap), and `capabilities`. There is no `context_window` field.

**Stop details (GA, Opus 4.7+):** `response.stop_details` is populated **only when `stop_reason ==
"refusal"`** (fields: `type: "refusal"`, `category` -- an open set, e.g. `"cyber"`, `"bio"`,
`"reasoning_extraction"`, `"frontier_llm"`, or `null`; see the docs for the full list -- and `explanation`).
It is `null` for every other `stop_reason` (`end_turn`, `max_tokens`, `tool_use`, `pause_turn`, ...) --
always guard before reading.

**Client config (no beta):** `timeout` default 10 min; **units differ by SDK** -- Python/Ruby: seconds;
TypeScript: **milliseconds**; Go `option.WithRequestTimeout(time.Duration)`; Java `Duration`; C# `TimeSpan`.
TS scales the default up to 60 min for large `max_tokens` on non-streaming requests; Java does so for
streaming requests (Java non-streaming scales 30s-10 min). `max_retries`/`maxRetries` default 2 (retries
408/409/429/5xx + connection errors). `base_url` (or `ANTHROPIC_BASE_URL` env). Per-request override: Python
`client.with_options(timeout=5.0).messages.create(...)`; TS `client.messages.create({...}, {timeout:
5_000})`; Ruby `request_options: {timeout: 5}`. Timeouts are retried -- wall-clock can reach `timeout x
(max_retries+1)`.

## Workload Identity Federation (Quick Reference)

**GA, no beta header.** Construct the normal zero-arg client (`Anthropic()` / `new Anthropic()` /
`anthropic.NewClient()` / `AnthropicOkHttpClient.fromEnv()`); the SDK auto-detects WIF when **all** of
`ANTHROPIC_FEDERATION_RULE_ID`, `ANTHROPIC_ORGANIZATION_ID`, `ANTHROPIC_SERVICE_ACCOUNT_ID`, and
```

```
`ANTHROPIC_IDENTITY_TOKEN_FILE` (or `ANTHROPIC_IDENTITY_TOKEN`) are set, exchanges the JWT at
`/v1/oauth/token`, and auto-refreshes. `ANTHROPIC_WORKSPACE_ID` does not gate activation -- required only
when the federation rule spans multiple workspaces (else 400 `workspace_id_required`), optional for
single-workspace rules. `ANTHROPIC_API_KEY` or `ANTHROPIC_AUTH_TOKEN` (even empty) outrank WIF, and a set
`ANTHROPIC_PROFILE` also wins over the federation env vars (a missing named profile is an error, not a
fall-through) -- unset all three.

---

## Reference Documentation

The relevant documentation for your detected language is included below in `<doc>` tags. Each tag has a
`path` attribute showing its original file path. Use this to find the right section:

### Quick Task Reference

> All SDK languages use the same per-language `claude-api/` directory layout (cURL: `curl/examples.md`). Not
every language has every file -- if a file is absent, that feature's example is not yet documented for that
language; fall back to the cURL shape or WebFetch the SDK repo.

**Single text classification/summarization/extraction/Q&A:**
-> Refer to `unknown/claude-api/README.md`

**Chat UI or real-time response display:**
-> Refer to `unknown/claude-api/README.md` + `unknown/claude-api/streaming.md`

**Long-running conversations (may exceed context window):**
-> Refer to `unknown/claude-api/README.md` -- see Compaction section

**Migrating to a newer model or replacing a retired model:**
-> Refer to `shared/model-migration.md`

**Prompt caching / optimize caching / "why is my cache hit rate low":**
-> Refer to `shared/prompt-caching.md` + `unknown/claude-api/README.md` (Prompt Caching section)

**Audit / clean up prompts, skills, or tool descriptions for outdated patterns ("cruft"):**
-> Refer to `shared/prompt-audit.md`

**Count tokens in a file / prompt / diff ("how many tokens is X"):**
-> Refer to `shared/token-counting.md` -- use `messages.count_tokens`, never `tiktoken`

**Function calling / tool use / agents:**
-> Refer to `unknown/claude-api/README.md` + `shared/tool-use-concepts.md` + `unknown/claude-api/tool-use.md`

**Batch processing (non-latency-sensitive):**
-> Refer to `unknown/claude-api/README.md` + `unknown/claude-api/batches.md`

**File uploads across multiple requests:**
-> Refer to `unknown/claude-api/README.md` + `unknown/claude-api/files-api.md`

**Agent design (tool surface, context management, caching strategy):**
-> Refer to `shared/agent-design.md`

**Anthropic CLI (`ant`) -- terminal access, version-controlled agent/environment YAML, scripting:**
-> Refer to `shared/anthropic-cli.md`

**Managed Agents (server-managed stateful agents):**
-> Refer to `shared/managed-agents-overview.md` and the rest of the `shared/managed-agents-*.md` files. For
Python, TypeScript, Go, Ruby, PHP, and Java, read the `managed-agents/README.md` in the language folder for
code examples. For cURL, read `curl/managed-agents.md`. C# has beta Managed Agents support -- use
`curl/managed-agents.md` as the wire-level reference (the C# SDK mirrors it via `client.Beta.Agents`; see
`csharp/claude-api/README.md`).

**Error handling:**
-> Refer to `shared/error-codes.md`

**Latest docs via WebFetch:**
-> Refer to `shared/live-sources.md` for URLs

No project language was auto-detected. Ask the user which language they are using, then refer to the matching
```

````
docs below.

---

## Included Documentation

<doc path="csharp/claude-api/README.md">
# Claude API -- C#

> **Note:** The C# SDK is the official Anthropic SDK for C#. Tool use is supported via the Messages API with
a beta `BetaToolRunner` for automatic tool execution loops. The SDK also supports Microsoft.Extensions.AI
IChatClient integration with function invocation and Managed Agents (beta).

## Namespace Reference

Types are organized by namespace. If a type you need isn't shown in an example below, locate it via this
table first -- don't block on fetching SDK source over the network.

| `using` | Contains |
|---|---|
| `Anthropic` | `AnthropicClient`, top-level options |
| `Anthropic.Models.Messages` | non-beta request/response types -- `MessageCreateParams`, `Model`, `Role`,
`ContentBlock`, `TextBlock`, `ToolUseBlock`, `ToolResultBlockParam`, `Tool*` (tool definition classes) |
| `Anthropic.Models.Beta.Messages` | beta-endpoint equivalents -- `MessageCreateParams`, `BetaMessage`,
`BetaTool*`, `Speed`, `BetaRequestMcpServerUrlDefinition`, context-editing/compaction configs |
| `Anthropic.Models.Beta` | shared beta constants |
| `Anthropic.Models.Beta.Files` | Files API types |
| `Anthropic.Models.Messages.Batches` | Batch API types |
| `Anthropic.Helpers.Beta` | `BetaToolRunner`, beta helper utilities |
| `Anthropic.Exceptions` | `AnthropicApiException`, `AnthropicRateLimitException`, `Anthropic5xxException`,
etc. -- see `shared/error-codes.md` |
| `Anthropic.Bedrock` / `Anthropic.Vertex` / `Anthropic.Foundry` / `Anthropic.Aws` | platform clients
(separate NuGet packages): `AnthropicBedrockMantleClient`, `AnthropicFoundryClient`, `AnthropicAwsClient` |

`client.Messages.*` uses non-beta types; `client.Beta.Messages.*` uses the `Anthropic.Models.Beta.Messages`
types. Both namespaces define a `MessageCreateParams` -- pick the one matching the client path you call.

### Key types per feature

Write from this table instead of reflecting the SDK assembly. Endpoint column tells you whether to use
`client.Messages.*` or `client.Beta.Messages.*`.

| Feature | Endpoint | Key C# types (namespace per table above) |
|---|---|---|
| User profiles | beta | `client.Beta.UserProfiles.Create(...)` / `.Retrieve(id)` / `.List()`. Pass the
returned profile id on the beta messages call. Requires a beta header -- check the SDK's beta-headers
reference for the current flag. |
| Agent Skills | beta | `BetaContainerParams` (with `Skills = [new BetaSkillParams { ... }]`),
`BetaCodeExecutionTool20250825`. `Betas = ["code-execution-2025-08-25", "skills-2025-10-02"]`. Download the
output via `client.Beta.Files.Download(fileId)`. |
| Advisor tool | beta | `BetaAdvisorTool20260301` -- may not be in all SDK releases yet |
| Cache diagnostics | beta | `Diagnostics = new() { PreviousMessageID = ... }`, `BetaCacheControlEphemeral`,
`BetaContentBlockParam` |
| Context editing | beta | `ContextManagement = new BetaContextManagementConfig { Edits = [new
BetaClearToolUses20250919Edit()] }`. `Betas = ["context-management-2025-06-27"]` (not `compact-2026-01-12` --
that's for `BetaCompact20260112Edit`). |
| Memory tool | non-beta | `Tools = [new ToolUnion(new MemoryTool20250818())]` |
| Programmatic tool calling | non-beta | `CodeExecutionTool20260120`, `ToolResultBlockParam`,
`ContentBlockParam` |
| Task budgets | beta | `BetaOutputConfig` with `TaskBudget = new BetaTokenTaskBudget { ... }` |
| Tool search | non-beta | `new ToolUnion(new ToolSearchToolRegex20251119 { Type =
ToolSearchToolRegex20251119Type.ToolSearchToolRegex20251119 })` -- `Type` must be set explicitly. |
| Web search | non-beta | `new ToolUnion(new WebSearchTool20260209())` -- the latest variant with dynamic
filtering (Claude Fable 5 + Claude Opus 5 + Opus 4.8/4.7/4.6 + Claude Sonnet 5 + Sonnet 4.6). For older
models or Vertex, use `WebSearchTool20250305()` |

### Discovering type and member names

If a type or member you need isn't in the tables above, `strings
~/.nuget/packages/anthropic/*/lib/*/Anthropic.dll | grep -i <term>` is fast and sufficient for locating class
````

````
and property names. **Do not escalate to a `dotnet run` reflection probe** to dump members precisely -- the
first compile is slow enough to be backgrounded in many environments, trapping you in a polling loop.
Instead, write `Program.cs` using the names `strings | grep` found; if a member name is wrong the compiler
error (`error CS1061: 'X' does not contain a definition for 'Y'`) points at it in a few seconds, faster than
any reflection probe.

Note that `strings` will not surface wire-format snake_case field names (`output_tokens`, `stop_reason`) --
those are stored in the DLL differently. **C# properties are the PascalCase equivalent of the wire field**
(`response.Usage.OutputTokens`, `response.StopReason`). If you know the wire field name from the docs, write
the PascalCase property and compile; do not probe for the snake_case string.

### Minimal working skeleton

**Write a plain `Program.cs` body** -- `using` statements followed by top-level statements, as below. Do
**not** add a `#!/usr/bin/env dotnet` shebang or `#:package Anthropic@*` directive: those are .NET
file-based-app syntax and fail with `CS1024: Preprocessor directive expected` when the file is compiled via
an existing `.csproj`. The standard project setup (per the [C#
quickstart](https://platform.claude.com/docs/en/get-started): `dotnet new console` -> `dotnet add package
Anthropic` -> edit `Program.cs` -> `dotnet run`) provides the `.csproj` and package reference.

Start from this -- it compiles as-is. Fill in the feature-specific fields; do not spend turns running
reflection or XML-doc inspection to discover type names first.

```csharp
using System;
using Anthropic;
using Anthropic.Models.Messages;       // or Anthropic.Models.Beta.Messages for beta endpoints

AnthropicClient client = new();

var message = await client.Messages.Create(new MessageCreateParams
{
    Model = "claude-opus-5",
    MaxTokens = 1024,
    Messages = [ new() { Role = Role.User, Content = "Hello, Claude" } ],
});

Console.WriteLine(message);
```

For beta features (anything behind an `anthropic-beta` header), use the beta client path and namespace --
same overall shape:

```csharp
using System;
using Anthropic;
using Anthropic.Models.Beta.Messages;

AnthropicClient client = new();

var response = await client.Beta.Messages.Create(new MessageCreateParams
{
    Model = "claude-opus-5",
    MaxTokens = 4096,
    Betas = ["<beta-flag>"],
    Messages = [ new() { Role = Role.User, Content = "..." } ],
    // Tools = new BetaToolUnion[] { new BetaSomeTool { ... } },   // for tool features
});

Console.WriteLine(response);
```

If a type name the feature needs isn't in this file, write it following the naming pattern in the Namespace
Reference above and fix from compiler output -- producing a `Program.cs` and iterating beats researching.

### Common C# compile errors

- **CS8803 (top-level statements must precede type declarations):** put any `record`/`class`/`struct`
definitions **after** the last top-level statement, at the end of the file. A record defined above `var
client = new AnthropicClient()` will not compile.
````

```
- **`await foreach` on a `Task<...Page>`:** `client.Models.List()` returns a `Task<ModelListPage>`, which is
not directly async-enumerable. Await it first, then iterate: `var page = await client.Models.List(); foreach
(var m in page.Items) {...}`. For auto-pagination, check whether the page type exposes
`AutoPagingEachAsync()` or similar before reaching for `await foreach`.

## Installation

```bash
dotnet add package Anthropic
```

Client Initialization

```csharp
using Anthropic;

// Default (uses ANTHROPIC_API_KEY env var)
AnthropicClient client = new();

// Explicit API key (use environment variables -- never hardcode keys)
AnthropicClient client = new() {
    ApiKey = Environment.GetEnvironmentVariable("ANTHROPIC_API_KEY")
};
```

Basic Message Request

```csharp
using Anthropic.Models.Messages;

var parameters = new MessageCreateParams
{
    Model = "claude-opus-5",
    MaxTokens = 16000,
    Messages = [new() { Role = Role.User, Content = "What is the capital of France?" }]
};
var response = await client.Messages.Create(parameters);

// ContentBlock is a union wrapper. .Value unwraps to the variant object,
// then OfType<T> filters to the type you want. Or use the TryPick* idiom
// shown in the Thinking section below.
foreach (var text in response.Content.Select(b => b.Value).OfType<TextBlock>())
{
    Console.WriteLine(text.Text);
}
```

Thinking

Adaptive thinking is the recommended mode for Claude 4.6+ models. Claude decides dynamically when and how
much to think.

> **Fable 5, Claude Opus 5, Opus 4.8, Opus 4.7, Opus 4.6, and Sonnet 4.6:** Use adaptive thinking (below).
`new ThinkingConfigEnabled { BudgetTokens = N }` is removed on Fable 5, Claude Opus 5, Opus 4.8, and 4.7 (400
if sent); deprecated on Opus 4.6 and Sonnet 4.6.
> **Claude Opus 5:** thinking is on by default -- omitting `Thinking` runs adaptive (`ThinkingConfigAdaptive`
is equivalent), unlike Opus 4.8/4.7 where omitting it meant no thinking. `ThinkingConfigDisabled` is accepted
only at effort `high` or lower; pairing it with `xhigh`/`max` returns a 400.
> **Older models:** Use `new ThinkingConfigEnabled { BudgetTokens = N }` (budget must be < `MaxTokens`, min
1024).

```csharp
using Anthropic.Models.Messages;

var response = await client.Messages.Create(new MessageCreateParams
{
```
```

```
    Model = "claude-opus-5",
    MaxTokens = 16000,
    // ThinkingConfigParam? implicitly converts from the concrete variant classes --
    // no wrapper needed.
    // display opt-in: default is omitted (empty thinking text) on Fable 5 / Mythos 5 / Claude Opus 5 / Opus
4.8 / 4.7
    Thinking = new ThinkingConfigAdaptive { Display = Display.Summarized },
    Messages =
    [
        new() { Role = Role.User, Content = "Solve: 27 * 453" },
    ],
});

// ThinkingBlock(s) precede TextBlock in Content. TryPick* narrows the union.
foreach (var block in response.Content)
{
    if (block.TryPickThinking(out ThinkingBlock? t))
    {
        Console.WriteLine($"[thinking] {t.Thinking}");
    }
    else if (block.TryPickText(out TextBlock? text))
    {
        Console.WriteLine(text.Text);
    }
}
```

Alternative to `TryPick*`: `.Select(b => b.Value).OfType<ThinkingBlock>()` (same LINQ pattern as the Basic Message example).

Context Editing / Compaction (Beta)

Beta-namespace prefix is inconsistent (source-verified against `src/Anthropic/Models/Beta/Messages/*.cs` @ 12.9.0). No prefix: `MessageCreateParams`, `MessageCountTokensParams`, `Role`, `Speed`. **Everything else has the `Beta` prefix**: `BetaMessageParam`, `BetaMessage`, `BetaContentBlock`, `BetaToolUseBlock`, all block param types. The unprefixed `Role` WILL collide with `Anthropic.Models.Messages.Role` if you import both namespaces (CS0104). Safest: import only Beta; if mixing, alias the beta `Role`:

```csharp
using Anthropic.Models.Beta.Messages;
using NonBeta = Anthropic.Models.Messages;  // only if you also need non-beta types
// Now: MessageCreateParams, BetaMessageParam, Role (beta's), NonBeta.Role (if needed)
```

`BetaMessage.Content` is `IReadOnlyList<BetaContentBlock>` -- a 15-variant discriminated union. Narrow with `TryPick*`. **Response `BetaContentBlock` is NOT assignable to param `BetaContentBlockParam`** -- there's no `.ToParam()` in C#. Round-trip by converting each block:

```csharp
using Anthropic.Models.Beta.Messages;

var betaParams = new MessageCreateParams   // no Beta prefix -- see unprefixed list above
{
    Model = "claude-opus-5",
    MaxTokens = 16000,
    Betas = ["compact-2026-01-12"],
    ContextManagement = new BetaContextManagementConfig
    {
        Edits = [new BetaCompact20260112Edit()],
    },
    Messages = messages,
};
BetaMessage resp = await client.Beta.Messages.Create(betaParams);

foreach (BetaContentBlock block in resp.Content)
{
    if (block.TryPickCompaction(out BetaCompactionBlock? compaction))
```

```
    {
        // Content is nullable -- compaction can fail server-side
        Console.WriteLine($"compaction summary: {compaction.Content}");
    }
}

// Context-edit metadata lives on a separate nullable field
if (resp.ContextManagement is { } ctx)
{
    foreach (var edit in ctx.AppliedEdits)
        Console.WriteLine($"cleared {edit.ClearedInputTokens} tokens");
}

// ROUND-TRIP: BetaMessageParam.Content is BetaMessageParamContent (a string|list
// union). It implicit-converts from List<BetaContentBlockParam>, NOT from the
// response's IReadOnlyList<BetaContentBlock>. Convert each block:
List<BetaContentBlockParam> paramBlocks = [];
foreach (var b in resp.Content)
{
    if (b.TryPickText(out var t)) paramBlocks.Add(new BetaTextBlockParam { Text = t.Text });
    else if (b.TryPickCompaction(out var c)) paramBlocks.Add(new BetaCompactionBlockParam { Content =
c.Content });
    // ... other variants as needed
}
messages.Add(new BetaMessageParam { Role = Role.Assistant, Content = paramBlocks });
```

All 15 `BetaContentBlock.TryPick*` variants: `Text`, `Thinking`, `RedactedThinking`, `ToolUse`, `ServerToolUse`, `WebSearchToolResult`, `WebFetchToolResult`, `CodeExecutionToolResult`, `BashCodeExecutionToolResult`, `TextEditorCodeExecutionToolResult`, `ToolSearchToolResult`, `McpToolUse`, `McpToolResult`, `ContainerUpload`, `Compaction`.

`BetaToolUseBlock.Input` is `IReadOnlyDictionary<string, JsonElement>` -- index by key then call the `JsonElement` extractor:

```csharp
if (block.TryPickToolUse(out BetaToolUseBlock? tu))
{
    int a = tu.Input["a"].GetInt32();
    string s = tu.Input["name"].GetString()!;
}
```

Effort Parameter

Effort is nested under `OutputConfig`, NOT a top-level property. `ApiEnum<string, Effort>` has an implicit conversion from the enum, so assign `Effort.High` directly.

```csharp
OutputConfig = new OutputConfig { Effort = Effort.High },
```

Values: `Effort.Low`, `Effort.Medium`, `Effort.High`, `Effort.Max`. Combine with `Thinking = new ThinkingConfigAdaptive()` for cost-quality control.

Prompt Caching

`System` takes `MessageCreateParamsSystem?` -- a union of `string` or `List<TextBlockParam>`. There is no `SystemTextBlockParam`; use plain `TextBlockParam`. The implicit conversion needs the concrete `List<TextBlockParam>` type (array literals won't convert). For placement patterns and the silent-invalidator audit checklist, see `shared/prompt-caching.md`.

```csharp
System = new List<TextBlockParam> {
    new() {
        Text = longSystemPrompt,
```

```
        CacheControl = new CacheControlEphemeral(),  // auto-sets Type = "ephemeral"
    },
},
```

Optional `Ttl` on `CacheControlEphemeral`: `new() { Ttl = Ttl.Ttl1h }` or `Ttl.Ttl5m`. `CacheControl` also exists on `Tool.CacheControl` and top-level `MessageCreateParams.CacheControl`.

Verify hits via `response.Usage.CacheCreationInputTokens` / `response.Usage.CacheReadInputTokens`.

Token Counting

```csharp
MessageTokensCount result = await client.Messages.CountTokens(new MessageCountTokensParams {
    Model = "claude-opus-5",
    Messages = [new() { Role = Role.User, Content = "Hello" }],
});
long tokens = result.InputTokens;
```

`MessageCountTokensParams.Tools` uses a different union type (`MessageCountTokensTool`) than `MessageCreateParams.Tools` (`ToolUnion`) -- if you're passing tools, the compiler will tell you when it matters.

PDF / Document Input

`DocumentBlockParam` takes a `DocumentBlockParamSource` union: `Base64PdfSource` / `UrlPdfSource` / `PlainTextSource` / `ContentBlockSource`. `Base64PdfSource` auto-sets `MediaType = "application/pdf"` and `Type = "base64"`.

```csharp
new MessageParam {
    Role = Role.User,
    Content = new List<ContentBlockParam> {
        new DocumentBlockParam { Source = new Base64PdfSource { Data = base64String } },
        new TextBlockParam { Text = "Summarize this PDF" },
    },
}
```

Fast Mode (Beta)

```csharp
var response = await client.Beta.Messages.Create(new MessageCreateParams {
    Model = "claude-opus-5", MaxTokens = 4096,
    Speed = Speed.Fast,
    Betas = ["fast-mode-2026-02-01"],
    Messages = [...],
});
```

Models API

```csharp
var page = await client.Models.List();
foreach (var m in page.Items) { Console.WriteLine(m.ID); }
var one = await client.Models.Retrieve("claude-opus-5");
```

Long Output (128k) + Prefill

Set `MaxTokens = 128000` on `client.Messages` and use the streaming path (see `streaming.md`). On Claude 4+ models, 128k output is native -- no `output-128k-*` beta header or beta namespace is needed.

````
**Prefilling the assistant message** (putting a trailing `Role.Assistant` message in the input) is **not
supported** on Claude Fable 5, Claude Opus 5, Opus 4.8, Opus 4.7, Opus 4.6, and Sonnet 4.6 -- requests return
a 400. Use `OutputConfig.Format` (structured outputs) instead.

## Stop Details

When `StopReason` is `"refusal"`, the response includes structured `StopDetails`:

```csharp
if (response.StopReason == "refusal" && response.StopDetails is { } details)
{
    Console.WriteLine($"Category: {details.Category}");
    Console.WriteLine($"Explanation: {details.Explanation}");
}
```

**Refusal fallbacks (Claude Fable 5) -- opt in by default.** Fallbacks are opt-in: without them a refused
request simply stops. In `claude-fable-5` code, include `Fallbacks = [new(Model.ClaudeOpus4_8)]` plus the
`AnthropicBeta.ServerSideFallback2026_06_01` beta on the beta messages call by default -- a policy decline is
re-served by the fallback model inside the same call. Not available on Amazon Bedrock, Vertex AI, or
Microsoft Foundry -- use the client-side handler there: `new AnthropicClient { Handlers = [new
BetaRefusalFallbackHandler { Fallbacks = [new(Model.ClaudeOpus4_8)] }] }` (namespace `Anthropic.Helpers`),
with per-conversation state via `BetaFallbackState.Create()` scoped with `using (fallbackState.Use()) { ...
}`. Full semantics (billing, sticky routing, streaming) and a runnable example: `shared/model-migration.md`
-> Migrating to Claude Fable 5 -> `refusal` stop reason, and the C# SDK repo's `examples/` (WebFetch via
`shared/live-sources.md`).

---

## Managed Agents (Beta)

The C# SDK supports Managed Agents via `client.Beta.Agents`, `client.Beta.Sessions`,
`client.Beta.Environments`, and related namespaces. See `shared/managed-agents-overview.md` for the
architecture and `curl/managed-agents.md` for the wire-level reference.
</doc>

<doc path="csharp/claude-api/batches.md">
# Message Batches -- C#

## Message Batches API

```csharp
var batch = await client.Messages.Batches.Create(new() {
    Requests = [
        new() { CustomID = "req-1", Params = new() { Model = "claude-opus-5", MaxTokens = 1024, Messages =
[...] } },
    ],
});
// Poll client.Messages.Batches.Retrieve(batch.ID) until ProcessingStatus == "ended",
// then iterate client.Messages.Batches.Results(batch.ID).
```
</doc>

<doc path="csharp/claude-api/files-api.md">
# Files API -- C#

## Files API (Beta)

Files live under `client.Beta.Files` (namespace `Anthropic.Models.Beta.Files`). `BinaryContent`
implicit-converts from `Stream` and `byte[]`.

```csharp
using Anthropic.Models.Beta.Files;
using Anthropic.Models.Beta.Messages;

FileMetadata meta = await client.Beta.Files.Upload(
    new FileUploadParams { File = File.OpenRead("doc.pdf") });

// Referencing the uploaded file requires Beta message types:
new BetaRequestDocumentBlock {
````
````

```
    Source = new BetaFileDocumentSource { FileID = meta.ID },
}
```

The non-beta `DocumentBlockParamSource` union has no file-ID variant -- file references need
`client.Beta.Messages.Create()`.

</doc>

<doc path="csharp/claude-api/streaming.md">
Streaming -- C#

Streaming

```csharp
using Anthropic.Models.Messages;

var parameters = new MessageCreateParams
{
    Model = Model.ClaudeOpus4_8,
    MaxTokens = 64000,
    Messages = [new() { Role = Role.User, Content = "Write a haiku" }]
};

await foreach (RawMessageStreamEvent streamEvent in client.Messages.CreateStreaming(parameters))
{
    if (streamEvent.TryPickContentBlockDelta(out var delta) &&
        delta.Delta.TryPickText(out var text))
    {
        Console.Write(text.Text);
    }
}
```

`RawMessageStreamEvent` TryPick methods (naming drops the `Message`/`Raw` prefix): `TryPickStart`,
`TryPickDelta`, `TryPickStop`, `TryPickContentBlockStart`, `TryPickContentBlockDelta`,
`TryPickContentBlockStop`. There is no `TryPickMessageStop` -- use `TryPickStop`.

</doc>

<doc path="csharp/claude-api/tool-use.md">
Tool Use -- C#

For conceptual overview (tool definitions, tool choice, tips), see
[shared/tool-use-concepts.md](../../shared/tool-use-concepts.md).

Tool Use

Defining a tool

`Tool` (NOT `ToolParam`) with an `InputSchema` record. `InputSchema.Type` is auto-set to `"object"` by the
constructor -- don't set it. `ToolUnion` has an implicit conversion from `Tool`, triggered by the collection
expression `[...]`.

```csharp
using System.Text.Json;
using Anthropic.Models.Messages;

var parameters = new MessageCreateParams
{
    Model = Model.ClaudeSonnet4_6,
    MaxTokens = 16000,
    Tools = [
        new Tool {
            Name = "get_weather",
            Description = "Get the current weather in a given location",
            InputSchema = new() {
                Properties = new Dictionary<string, JsonElement> {
```

```
                    ["location"] = JsonSerializer.SerializeToElement(
                        new { type = "string", description = "City name" }),
                },
                Required = ["location"],
            },
        },
    ],
    Messages = [new() { Role = Role.User, Content = "Weather in Paris?" }],
};
```

Derived from `anthropic-sdk-csharp/src/Anthropic/Models/Messages/Tool.cs` and `ToolUnion.cs:799` (implicit conversion).

See [shared tool use concepts](../../shared/tool-use-concepts.md) for the loop pattern.
Converting response content to the follow-up assistant message

When echoing Claude's response back in the assistant turn, **there is no `.ToParam()` helper** -- manually reconstruct each `ContentBlock` variant as its `*Param` counterpart. Do NOT use `new ContentBlockParam(block.Json)`: it compiles and serializes, but `.Value` stays `null` so `TryPick*`/`Validate()` fail (degraded JSON pass-through, not the typed path).

```csharp
using Anthropic.Models.Messages;

Message response = await client.Messages.Create(parameters);

// No .ToParam() -- reconstruct per variant. Implicit conversions from each
// *Param type to ContentBlockParam mean no explicit wrapper.
List<ContentBlockParam> assistantContent = [];
List<ContentBlockParam> toolResults = [];
foreach (ContentBlock block in response.Content)
{
    if (block.TryPickText(out TextBlock? text))
    {
        assistantContent.Add(new TextBlockParam { Text = text.Text });
    }
    else if (block.TryPickThinking(out ThinkingBlock? thinking))
    {
        // Signature MUST be preserved -- the API rejects tampering
        assistantContent.Add(new ThinkingBlockParam
        {
            Thinking = thinking.Thinking,
            Signature = thinking.Signature,
        });
    }
    else if (block.TryPickRedactedThinking(out RedactedThinkingBlock? redacted))
    {
        assistantContent.Add(new RedactedThinkingBlockParam { Data = redacted.Data });
    }
    else if (block.TryPickToolUse(out ToolUseBlock? toolUse))
    {
        // ToolUseBlock has required Caller; ToolUseBlockParam.Caller is optional -- don't copy it
        assistantContent.Add(new ToolUseBlockParam
        {
            ID = toolUse.ID,
            Name = toolUse.Name,
            Input = toolUse.Input,
        });
        // Execute the tool; collect ONE result per tool_use block -- the API
        // rejects the follow-up if any tool_use ID lacks a matching tool_result.
        string result = ExecuteYourTool(toolUse.Name, toolUse.Input);
        toolResults.Add(new ToolResultBlockParam
        {
            ToolUseID = toolUse.ID,
            Content = result,
        });
    }
}
```

```
// Follow-up: prior messages + assistant echo + user tool_result(s)
List<MessageParam> followUpMessages =
[
    .. parameters.Messages,
    new() { Role = Role.Assistant, Content = assistantContent },
    new() { Role = Role.User, Content = toolResults },
];
```

`ToolResultBlockParam` has no tuple constructor -- use the object initializer. `Content` is a string-or-list union; a plain `string` implicitly converts.

Structured Output

```csharp
OutputConfig = new OutputConfig {
    Format = new JsonOutputFormat {
        Schema = new Dictionary<string, JsonElement> {
            ["type"] = JsonSerializer.SerializeToElement("object"),
            ["properties"] = JsonSerializer.SerializeToElement(
                new { name = new { type = "string" } }),
            ["required"] = JsonSerializer.SerializeToElement(new[] { "name" }),
        },
    },
},
```

`JsonOutputFormat.Type` is auto-set to `"json_schema"` by the constructor. `Schema` is `required`.

Anthropic-Defined Tools

Web search, bash, text editor, and code execution are Anthropic-defined tools with built-in schemas. Web search and code execution are server-executed; bash and text editor are client-executed (you handle the `tool_use` locally -- see `shared/tool-use-concepts.md`). Type names are version-suffixed; constructors auto-set `name`/`type`. **Wrap each in `new ToolUnion(...)` explicitly.**

```csharp
Tools = [
    new ToolUnion(new WebSearchTool20260209()),
    new ToolUnion(new ToolBash20250124()),
    new ToolUnion(new ToolTextEditor20250728()),
    new ToolUnion(new CodeExecutionTool20260120()),
],
```

Also available: `new ToolUnion(new WebFetchTool20260209())`, `new ToolUnion(new MemoryTool20250818())`. `WebSearchTool20260209` optionals: `AllowedDomains`, `BlockedDomains`, `MaxUses`, `UserLocation`.

Tool Runner (Beta)

The C# SDK provides a `BetaToolRunner` for automatic tool execution loops. Define tools with raw JSON schemas, and the runner handles the API call -> tool execution -> result feedback loop.

```csharp
using Anthropic.Models.Beta.Messages;

// Define tools and create params as shown in the Tool Use section above,
// but using the beta namespace types (BetaToolUnion, etc.)
var runner = client.Beta.Messages.ToolRunner(betaParams);

await foreach (BetaMessage message in runner)
{
    foreach (var block in message.Content)
    {
```

```
        if (block.TryPickText(out var text))
        {
            Console.WriteLine(text.Text);
        }
    }
}
```

</doc>

<doc path="curl/examples.md">
Claude API -- cURL / Raw HTTP

Use these examples when the user needs raw HTTP requests or is working in a language without an official SDK.

Setup

```bash
export ANTHROPIC_API_KEY="your-api-key"
```

Basic Message Request

```bash
curl https://api.anthropic.com/v1/messages \
  -H "Content-Type: application/json" \
  -H "x-api-key: $ANTHROPIC_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -d '{
    "model": "claude-opus-5",
    "max_tokens": 16000,
    "messages": [
      {"role": "user", "content": "What is the capital of France?"}
    ]
  }'
```

Parsing the response

Use `jq` to extract fields from the JSON response. Do not use `grep`/`sed` --
JSON strings can contain any character and regex parsing will break on quotes,
escapes, or multi-line content.

```bash
# Capture the response, then extract fields
response=$(curl -s https://api.anthropic.com/v1/messages \
  -H "Content-Type: application/json" \
  -H "x-api-key: $ANTHROPIC_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -d '{"model":"claude-opus-5","max_tokens":16000,"messages":[{"role":"user","content":"Hello"}]}')

# Print the first text block (-r strips the JSON quotes)
echo "$response" | jq -r '.content[0].text'

# Read usage fields
input_tokens=$(echo "$response" | jq -r '.usage.input_tokens')
output_tokens=$(echo "$response" | jq -r '.usage.output_tokens')

# Read stop reason (for tool-use loops)
stop_reason=$(echo "$response" | jq -r '.stop_reason')

# Extract all text blocks (content is an array; filter to type=="text")
echo "$response" | jq -r '.content[] | select(.type == "text") | .text'
```

```
## Streaming (SSE)

```bash
curl https://api.anthropic.com/v1/messages \
  -H "Content-Type: application/json" \
  -H "x-api-key: $ANTHROPIC_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -d '{
    "model": "claude-opus-5",
    "max_tokens": 64000,
    "stream": true,
    "messages": [{"role": "user", "content": "Write a haiku"}]
  }'
```

The response is a stream of Server-Sent Events:

```
event: message_start
data: {"type":"message_start","message":{"id":"msg_...","type":"message",...}}

event: content_block_start
data: {"type":"content_block_start","index":0,"content_block":{"type":"text","text":""}}

event: content_block_delta
data: {"type":"content_block_delta","index":0,"delta":{"type":"text_delta","text":"Hello"}}

event: content_block_stop
data: {"type":"content_block_stop","index":0}

event: message_delta
data: {"type":"message_delta","delta":{"stop_reason":"end_turn"},"usage":{"output_tokens":12}}

event: message_stop
data: {"type":"message_stop"}
```

Tool Use

```bash
curl https://api.anthropic.com/v1/messages \
  -H "Content-Type: application/json" \
  -H "x-api-key: $ANTHROPIC_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -d '{
    "model": "claude-opus-5",
    "max_tokens": 16000,
    "tools": [{
      "name": "get_weather",
      "description": "Get current weather for a location",
      "input_schema": {
        "type": "object",
        "properties": {
          "location": {"type": "string", "description": "City name"}
        },
        "required": ["location"]
      }
    }],
    "messages": [{"role": "user", "content": "What is the weather in Paris?"}]
  }'
```

When Claude responds with a `tool_use` block, send the result back:

```bash
curl https://api.anthropic.com/v1/messages \
  -H "Content-Type: application/json" \
```
```

```
  -H "x-api-key: $ANTHROPIC_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -d '{
    "model": "claude-opus-5",
    "max_tokens": 16000,
    "tools": [{
      "name": "get_weather",
      "description": "Get current weather for a location",
      "input_schema": {
        "type": "object",
        "properties": {
          "location": {"type": "string", "description": "City name"}
        },
        "required": ["location"]
      }
    }],
    "messages": [
      {"role": "user", "content": "What is the weather in Paris?"},
      {"role": "assistant", "content": [
        {"type": "text", "text": "Let me check the weather."},
        {"type": "tool_use", "id": "toolu_abc123", "name": "get_weather", "input": {"location": "Paris"}}
      ]},
      {"role": "user", "content": [
        {"type": "tool_result", "tool_use_id": "toolu_abc123", "content": "72degF and sunny"}
      ]}
    ]
  }'
```

Prompt Caching

Put `cache_control` on the last block of the stable prefix. See `shared/prompt-caching.md` for placement patterns and the silent-invalidator audit checklist.

```bash
curl https://api.anthropic.com/v1/messages \
  -H "Content-Type: application/json" \
  -H "x-api-key: $ANTHROPIC_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -d '{
    "model": "claude-opus-5",
    "max_tokens": 16000,
    "system": [
      {"type": "text", "text": "<large shared prompt...>", "cache_control": {"type": "ephemeral"}}
    ],
    "messages": [{"role": "user", "content": "Summarize the key points"}]
  }'
```

For 1-hour TTL: `"cache_control": {"type": "ephemeral", "ttl": "1h"}`. Top-level `"cache_control"` on the request body auto-places on the last cacheable block. Verify hits via the response `usage.cache_creation_input_tokens` / `usage.cache_read_input_tokens` fields.

Extended Thinking

> **Fable 5, Claude Opus 5, Opus 4.8, Opus 4.7, Opus 4.6, and Sonnet 4.6:** Use adaptive thinking. `budget_tokens` is removed on Fable 5, Claude Opus 5, Opus 4.8, and 4.7 (400 if sent); deprecated on Opus 4.6 and Sonnet 4.6.
> **Claude Opus 5:** thinking is on by default -- omitting `"thinking"` runs adaptive (`{"type": "adaptive"}` is equivalent), unlike Opus 4.8/4.7 where omitting it meant no thinking. `{"type": "disabled"}` is accepted only at effort `high` or lower; pairing it with `xhigh`/`max` returns a 400.
> **Older models:** Use `"type": "enabled"` with `"budget_tokens": N` (must be < `max_tokens`, min 1024).

```bash
# Fable 5 / Claude Opus 5 / Opus 4.8 / 4.7 / 4.6: adaptive thinking (recommended)
curl https://api.anthropic.com/v1/messages \
```

```
  -H "Content-Type: application/json" \
  -H "x-api-key: $ANTHROPIC_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -d '{
    "model": "claude-opus-5",
    "max_tokens": 16000,
    "thinking": {
      "type": "adaptive",
      "display": "summarized"
    },
    "output_config": {
      "effort": "high"
    },
    "messages": [{"role": "user", "content": "Solve this step by step..."}]
  }'
```

Refusal Fallbacks (Claude Fable 5) -- opt in by default

On `claude-fable-5`, safety classifiers may decline a request (HTTP 200 with `stop_reason: "refusal"`). Fallbacks are **opt-in**: without them the request simply stops. Include the `fallbacks` parameter and its beta header by default -- on a policy decline the API re-runs the same request on the fallback model inside the same call. A decline before any output isn't billed (a mid-stream decline bills the streamed partial); the rescue bills at the fallback model's own rates.

```bash
response=$(curl -s https://api.anthropic.com/v1/messages \
  -H "Content-Type: application/json" \
  -H "x-api-key: $ANTHROPIC_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -H "anthropic-beta: server-side-fallback-2026-06-01" \
  -d '{
    "model": "claude-fable-5",
    "max_tokens": 16000,
    "fallbacks": [{"model": "claude-opus-4-8"}],
    "messages": [{"role": "user", "content": "Hello"}]
  }')

# Which model produced the message
echo "$response" | jq -r '.model'

# Refusal on the final response means the whole chain refused
echo "$response" | jq -r '.stop_reason'

# Switch points: one fallback block per model that ran and declined this turn
echo "$response" | jq -r '.content[] | select(.type == "fallback") | "\(.from.model) declined; \(.to.model)
continued"'

# Served-by signal -- covers sticky turns, which carry no fallback block.
# Pair with stop_reason: the fallback model can itself refuse.
if [ "$(echo "$response" | jq -r '.stop_reason')" != "refusal" ] && \
   echo "$response" | jq -e '[.usage.iterations[]? | select(.type == "fallback_message")] | length > 0' >
/dev/null; then
  echo "fallback model served this turn"
fi
```

The header must be exactly `server-side-fallback-2026-06-01` **for this array form**; the newer `fallbacks: "default"` scalar form uses `server-side-fallback-2026-07-01` instead (see `shared/model-migration.md` -> Migrating to Claude Opus 5 -> New API features), and pairing either header with the other form returns a 400. The parameter is rejected on the Batches API and unavailable on Amazon Bedrock, Vertex AI, and Microsoft Foundry. Full semantics (sticky routing, billing, streaming, echoing fallback turns back): `shared/model-migration.md` -> Migrating to Claude Fable 5 -> `refusal` stop reason.

Required Headers

```
| Header              | Value              | Description               |
| ------------------- | ------------------ | ------------------------- |
| `Content-Type`      | `application/json` | Required                  |
| `x-api-key`         | Your API key       | Authentication            |
| `anthropic-version` | `2023-06-01`       | API version               |
| `anthropic-beta`    | Beta feature IDs   | Required for beta features |
</doc>

<doc path="curl/managed-agents.md">
# Managed Agents -- cURL / Raw HTTP

Use these examples when the user needs raw HTTP requests or is working without an SDK.

## Setup

```bash
export ANTHROPIC_API_KEY="your-api-key"

# Common headers
HEADERS=(
  -H "Content-Type: application/json"
  -H "x-api-key: $ANTHROPIC_API_KEY"
  -H "anthropic-version: 2023-06-01"
  -H "anthropic-beta: managed-agents-2026-04-01"
)
```

Create an Environment

```bash
curl -X POST https://api.anthropic.com/v1/environments \
  "${HEADERS[@]}" \
  -d '{
    "name": "my-dev-env",
    "config": {
      "type": "cloud",
      "networking": { "type": "unrestricted" }
    }
  }'
```

With restricted networking

```bash
curl -X POST https://api.anthropic.com/v1/environments \
  "${HEADERS[@]}" \
  -d '{
    "name": "restricted-env",
    "config": {
      "type": "cloud",
      "networking": {
        "type": "limited",
        "allow_package_managers": true,
        "allow_mcp_servers": true,
        "allowed_hosts": ["api.example.com"]
      }
    }
  }'
```

Create an Agent (required first step)

> ?? **There is no inline agent config.** Under `managed-agents-2026-04-01`, `model`/`system`/`tools` are
top-level fields on `POST /v1/agents`, not on the session. Always create the agent first -- the session only
takes `"agent": {"type": "agent", "id": "..."}`.
```

````
### Minimal

```bash
# 1. Create the agent
curl -X POST https://api.anthropic.com/v1/agents \
  "${HEADERS[@]}" \
  -d '{
    "name": "Coding Assistant",
    "model": "claude-opus-5",
    "tools": [{ "type": "agent_toolset_20260401" }]
  }'
# -> { "id": "agent_abc123", ... }

# 2. Start a session
curl -X POST https://api.anthropic.com/v1/sessions \
  "${HEADERS[@]}" \
  -d '{
    "agent": { "type": "agent", "id": "agent_abc123", "version": 1 },
    "environment_id": "env_abc123"
  }'
# -> { "id": "sesn_abc123", ... }
# Trace: https://platform.claude.com/workspaces/default/sessions/sesn_abc123  (swap 'default' for your
workspace ID if the API key is not in the Default workspace)
```

### With system prompt, custom tools, and GitHub repo

```bash
# 1. Create the agent
curl -X POST https://api.anthropic.com/v1/agents \
  "${HEADERS[@]}" \
  -d '{
    "name": "Code Reviewer",
    "model": "claude-opus-5",
    "system": "You are a senior code reviewer. Be thorough and constructive.",
    "tools": [
      { "type": "agent_toolset_20260401" },
      {
        "type": "custom",
        "name": "run_linter",
        "description": "Run the project linter on a file",
        "input_schema": {
          "type": "object",
          "properties": {
            "file_path": { "type": "string", "description": "Path to lint" }
          },
          "required": ["file_path"]
        }
      }
    ]
  }'

# 2. Start a session with the repo mounted
curl -X POST https://api.anthropic.com/v1/sessions \
  "${HEADERS[@]}" \
  -d '{
    "agent": { "type": "agent", "id": "agent_abc123", "version": 1 },
    "environment_id": "env_abc123",
    "title": "Code review session",
    "resources": [
      {
        "type": "github_repository",
        "url": "https://github.com/owner/repo",
        "mount_path": "/workspace/repo",
        "authorization_token": "ghp_...",
        "branch": "feature-branch"
      }
    ]
  }'
```
````

````
### With a session budget

```bash
# Create a session with a hard $25.00 spend cap (list-priced; USD only; create-only).
# amount is in minor units (cents) as an integer string: "2500" = $25.00
curl -X POST https://api.anthropic.com/v1/sessions \
  "${HEADERS[@]}" \
  -d '{
    "agent": { "type": "agent", "id": "agent_abc123" },
    "environment_id": "env_abc123",
    "budget": {
      "type": "limit",
      "max_list_cost": { "amount": "2500", "currency": "USD" }
    }
  }'

# Change the cap -- higher or lower, but it must exceed the consumed list cost.
# An accepted update resumes work paused at budget_reached
curl -X POST https://api.anthropic.com/v1/sessions/$SESSION_ID \
  "${HEADERS[@]}" \
  -d '{ "budget": { "type": "limit", "max_list_cost": { "amount": "4000", "currency": "USD" } } }'

# Remove the cap entirely -- one-way; a removed budget can never be re-added
curl -X POST https://api.anthropic.com/v1/sessions/$SESSION_ID \
  "${HEADERS[@]}" \
  -d '{ "budget": null }'
```

See `shared/managed-agents-core.md` ? Session budgets for list-cost composition, the settle-event allowlist
at the cap, and multiagent semantics.

---

## Send a User Message

```bash
curl -X POST https://api.anthropic.com/v1/sessions/$SESSION_ID/events \
  "${HEADERS[@]}" \
  -d '{
    "events": [
      {
        "type": "user.message",
        "content": [{ "type": "text", "text": "Review the auth module for security issues" }]
      }
    ]
  }'
```

---

## Stream Events (SSE)

```bash
curl -N https://api.anthropic.com/v1/sessions/$SESSION_ID/events/stream \
  "${HEADERS[@]}"
```

Response format:

```
event: session.status_running
data: {"type":"session.status_running","id":"sevt_...","processed_at":"..."}

event: agent.message
data: {"type":"agent.message","id":"sevt_...","content":[{"type":"text","text":"I'll
review..."}],"processed_at":"..."}

event: session.status_idle
data: {"type":"session.status_idle","id":"sevt_...","processed_at":"..."}
````
````

```

---

## Poll Events

```bash
# Get all events
curl https://api.anthropic.com/v1/sessions/$SESSION_ID/events \
  "${HEADERS[@]}"

# Paginated -- get next page of events
curl "https://api.anthropic.com/v1/sessions/$SESSION_ID/events?page=page_abc123" \
  "${HEADERS[@]}"
```

Provide Custom Tool Result

When the agent calls a custom tool, send the result back:

```bash
curl -X POST https://api.anthropic.com/v1/sessions/$SESSION_ID/events \
  "${HEADERS[@]}" \
  -d '{
    "events": [
      {
        "type": "user.custom_tool_result",
        "custom_tool_use_id": "sevt_abc123",
        "content": [{ "type": "text", "text": "No linting errors found." }]
      }
    ]
  }'
```

Interrupt a Running Session

```bash
curl -X POST https://api.anthropic.com/v1/sessions/$SESSION_ID/events \
  "${HEADERS[@]}" \
  -d '{
    "events": [
      {
        "type": "user.interrupt"
      }
    ]
  }'
```

Get Session Details

```bash
curl https://api.anthropic.com/v1/sessions/$SESSION_ID \
  "${HEADERS[@]}"
```

List Sessions

```bash
curl https://api.anthropic.com/v1/sessions \
  "${HEADERS[@]}"
```
```

````
---

## Delete a Session

```bash
curl -X DELETE https://api.anthropic.com/v1/sessions/$SESSION_ID \
  "${HEADERS[@]}"
```

---

## Upload a File

```bash
curl -X POST https://api.anthropic.com/v1/files \
  -H "x-api-key: $ANTHROPIC_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -H "anthropic-beta: files-api-2025-04-14" \
  -F "file=@path/to/file.txt" \
  -F "purpose=agent"
```

---

## List and Download Session Files

List files the agent wrote to `/mnt/session/outputs/` during a session, then download them.

```bash
# List files associated with a session
curl "https://api.anthropic.com/v1/files?scope_id=$SESSION_ID" \
  -H "x-api-key: $ANTHROPIC_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -H "anthropic-beta: files-api-2025-04-14,managed-agents-2026-04-01"

# Download a specific file
curl "https://api.anthropic.com/v1/files/$FILE_ID/content" \
  -H "x-api-key: $ANTHROPIC_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -H "anthropic-beta: files-api-2025-04-14,managed-agents-2026-04-01" \
  -o downloaded_file.txt
```

---

## List Agents

```bash
curl https://api.anthropic.com/v1/agents \
  "${HEADERS[@]}"
```

---

## MCP Server Integration

```bash
# 1. Agent declares MCP server (no auth here -- auth goes in a vault)
curl -X POST https://api.anthropic.com/v1/agents \
  "${HEADERS[@]}" \
  -d '{
    "name": "MCP Agent",
    "model": "claude-opus-5",
    "mcp_servers": [
      { "type": "url", "name": "my-tools", "url": "https://my-mcp-server.example.com/sse" }
    ],
    "tools": [
      { "type": "agent_toolset_20260401" },
      { "type": "mcp_toolset", "mcp_server_name": "my-tools" }
    ]
````
````

```
  }'

# 2. Session attaches vault containing credentials for that MCP server URL
curl -X POST https://api.anthropic.com/v1/sessions \
  "${HEADERS[@]}" \
  -d '{
    "agent": "agent_abc123",
    "environment_id": "env_abc123",
    "vault_ids": ["vlt_abc123"]
  }'
```

See `shared/managed-agents-tools.md` ?Vaults for creating vaults and adding credentials.

Tool Configuration

```bash
curl -X POST https://api.anthropic.com/v1/agents \
  "${HEADERS[@]}" \
  -d '{
    "name": "Restricted Agent",
    "model": "claude-opus-5",
    "tools": [
      {
        "type": "agent_toolset_20260401",
        "default_config": { "enabled": true },
        "configs": [
          { "name": "bash", "enabled": false }
        ]
      }
    ]
  }'
```
</doc>

<doc path="go/claude-api/README.md">
Claude API -- Go

> **Note:** The Go SDK supports the Claude API and beta tool use with `BetaToolRunner`. Agent SDK is not yet available for Go.

Installation

```bash
go get github.com/anthropics/anthropic-sdk-go
```

Client Initialization

```go
import (
    "github.com/anthropics/anthropic-sdk-go"
    "github.com/anthropics/anthropic-sdk-go/option"
)

// Default (uses ANTHROPIC_API_KEY env var)
client := anthropic.NewClient()

// Explicit API key
client := anthropic.NewClient(
    option.WithAPIKey("your-api-key"),
)
```

Model Constants

````
The Go SDK provides typed model constants: `anthropic.ModelClaudeFable5`, `anthropic.ModelClaudeOpus4_8`,
`anthropic.ModelClaudeOpus4_7`, `anthropic.ModelClaudeSonnet4_6`, `anthropic.ModelClaudeHaiku4_5_20251001`.
Default to Claude Opus 5 unless the user specifies otherwise; if they ask for Fable or the most powerful
model, use `anthropic.ModelClaudeFable5` (see `shared/models.md` for the full resolution table).

`anthropic.Model` is an alias for `string`, so a model with no typed constant yet -- including Claude Opus 5
-- is passed as the plain id: `Model: "claude-opus-5"`. Check the SDK release notes for a typed `Claude Opus
5` constant before assuming one exists.

---

## Basic Message Request

```go
response, err := client.Messages.New(context.Background(), anthropic.MessageNewParams{
    Model:     "claude-opus-5",
    MaxTokens: 16000,
    Messages: []anthropic.MessageParam{
        anthropic.NewUserMessage(anthropic.NewTextBlock("What is the capital of France?")),
    },
})
if err != nil {
    log.Fatal(err)
}
for _, block := range response.Content {
    switch variant := block.AsAny().(type) {
    case anthropic.TextBlock:
        fmt.Println(variant.Text)
    }
}
```

---

## Thinking

Enable Claude's internal reasoning by setting `Thinking` in `MessageNewParams`. The response will contain
`ThinkingBlock` content before the final `TextBlock`.

**Adaptive thinking is the recommended mode for Claude 4.6+ models.** Claude decides dynamically when and how
much to think. Combine with the `effort` parameter for cost-quality control.

Derived from `anthropic-sdk-go/message.go` (`ThinkingConfigParamUnion`, `ThinkingConfigAdaptiveParam`).

```go
// There is no ThinkingConfigParamOfAdaptive helper -- construct the union
// struct-literal directly and take the address of the variant.
adaptive := anthropic.ThinkingConfigAdaptiveParam{}
params := anthropic.MessageNewParams{
    Model:     anthropic.ModelClaudeSonnet4_6,
    MaxTokens: 16000,
    Thinking:  anthropic.ThinkingConfigParamUnion{OfAdaptive: &adaptive},
    Messages: []anthropic.MessageParam{
        anthropic.NewUserMessage(anthropic.NewTextBlock("How many r's in strawberry?")),
    },
}

resp, err := client.Messages.New(context.Background(), params)
if err != nil {
    log.Fatal(err)
}

// ThinkingBlock(s) precede TextBlock in content
for _, block := range resp.Content {
    switch b := block.AsAny().(type) {
    case anthropic.ThinkingBlock:
        fmt.Println("[thinking]", b.Thinking)
    case anthropic.TextBlock:
        fmt.Println(b.Text)
    }
````
````

```
}
```

> **Fable 5, Claude Opus 5, Opus 4.8, Opus 4.7, Opus 4.6, and Sonnet 4.6:** Use adaptive thinking (above). `ThinkingConfigParamOfEnabled(budgetTokens)` is removed on Fable 5, Claude Opus 5, Opus 4.8, and 4.7 (400 if sent); deprecated on Opus 4.6 and Sonnet 4.6.
> **Claude Opus 5:** thinking is on by default -- leaving `Thinking` unset runs adaptive (the adaptive union is equivalent), unlike Opus 4.8/4.7 where leaving it unset meant no thinking.
> **Older models:** Use `anthropic.ThinkingConfigParamOfEnabled(N)` (budget must be < `MaxTokens`, min 1024).

To disable: `anthropic.ThinkingConfigParamUnion{OfDisabled: &anthropic.ThinkingConfigDisabledParam{}}`. On Claude Opus 5 that is accepted only at effort `high` or lower -- pairing it with `xhigh`/`max` returns a 400.

Prompt Caching

`System` is `[]TextBlockParam`; set `CacheControl` on the last block to cache tools + system together. For placement patterns and the silent-invalidator audit checklist, see `shared/prompt-caching.md`.

```go
System: []anthropic.TextBlockParam{{
    Text:         longSystemPrompt,
    CacheControl: anthropic.NewCacheControlEphemeralParam(), // default 5m TTL
}},
```

For 1-hour TTL: `anthropic.CacheControlEphemeralParam{TTL: anthropic.CacheControlEphemeralTTLTTL1h}`. There's also a top-level `CacheControl` on `MessageNewParams` that auto-places on the last cacheable block.

Verify hits via `resp.Usage.CacheCreationInputTokens` / `resp.Usage.CacheReadInputTokens`.

Stop Details

When `StopReason` is `anthropic.StopReasonRefusal`, the response includes structured `StopDetails`:

```go
if resp.StopReason == anthropic.StopReasonRefusal {
    fmt.Println("Category:", resp.StopDetails.Category)     // e.g. "cyber", "bio", "reasoning_extraction", "frontier_llm", or "" -- see docs for the full set
    fmt.Println("Explanation:", resp.StopDetails.Explanation)
}
```

Refusal fallbacks (Claude Fable 5) -- opt in by default. Fallbacks are opt-in: without them a refused request simply stops. In `claude-fable-5` code, include `Fallbacks: []anthropic.BetaFallbackParam{{Model: "claude-opus-4-8"}}` plus the `anthropic.AnthropicBetaServerSideFallback2026_06_01` beta on `client.Beta.Messages.New` by default -- a policy decline is re-served by the fallback model inside the same call. Not available on Amazon Bedrock, Vertex AI, or Microsoft Foundry -- register the client-side middleware there: `option.WithMiddleware(betafallback.BetaRefusalFallbackMiddleware(...))` from `lib/betafallback`, with per-conversation state via `betafallback.WithBetaFallbackState(&betafallback.BetaFallbackState{})`. Full semantics (billing, sticky routing, streaming) and a runnable example: `shared/model-migration.md` -> Migrating to Claude Fable 5 -> `refusal` stop reason, and the Go SDK repo's `examples/` (WebFetch via `shared/live-sources.md`).

PDF / Document Input

`NewDocumentBlock` generic helper accepts any source type. `MediaType`/`Type` are auto-set.

```go
b64 := base64.StdEncoding.EncodeToString(pdfBytes)

msg := anthropic.NewUserMessage(
    anthropic.NewDocumentBlock(anthropic.Base64PDFSourceParam{Data: b64}),
    anthropic.NewTextBlock("Summarize this document"),
)
```

```

Other sources: `URLPDFSourceParam{URL: "https://..."}`, `PlainTextSourceParam{Data: "..."}`.

---

## Context Editing / Compaction (Beta)

Use `Beta.Messages.New` with `ContextManagement` on `BetaMessageNewParams`. There is no
`NewBetaAssistantMessage` -- use `.ToParam()` for the round-trip.

```go
params := anthropic.BetaMessageNewParams{
    Model:     "claude-opus-5",  // also supported: ModelClaudeOpus4_8, ModelClaudeSonnet4_6
    MaxTokens: 16000,
    Betas:     []anthropic.AnthropicBeta{"compact-2026-01-12"},
    ContextManagement: anthropic.BetaContextManagementConfigParam{
        Edits: []anthropic.BetaContextManagementConfigEditUnionParam{
            {OfCompact20260112: &anthropic.BetaCompact20260112EditParam{}},
        },
    },
    Messages: []anthropic.BetaMessageParam{ /* ... */ },
}

resp, err := client.Beta.Messages.New(ctx, params)
if err != nil {
    log.Fatal(err)
}

// Round-trip: append response to history via .ToParam()
params.Messages = append(params.Messages, resp.ToParam())

// Read compaction blocks from the response
for _, block := range resp.Content {
    if c, ok := block.AsAny().(anthropic.BetaCompactionBlock); ok {
        fmt.Println("compaction summary:", c.Content)
    }
}
```

Other edit types: `BetaClearToolUses20250919EditParam`, `BetaClearThinking20251015EditParam` -- these need
`Betas: []anthropic.AnthropicBeta{"context-management-2025-06-27"}`, not `compact-2026-01-12`.
</doc>

<doc path="go/claude-api/files-api.md">
Files API -- Go

Files API (Beta)

Under `client.Beta.Files`. Method is **`Upload`** (NOT `New`/`Create`), params struct is
`BetaFileUploadParams`. The `File` field takes an `io.Reader`; use `anthropic.File()` to attach a filename +
content-type for the multipart encoding.

```go
f, _ := os.Open("./upload_me.txt")
defer f.Close()

meta, err := client.Beta.Files.Upload(ctx, anthropic.BetaFileUploadParams{
    File:  anthropic.File(f, "upload_me.txt", "text/plain"),
    Betas: []anthropic.AnthropicBeta{anthropic.AnthropicBetaFilesAPI2025_04_14},
})
// meta.ID is the file_id to reference in subsequent message requests
```

Other `Beta.Files` methods: `List`, `Delete`, `Download`, `GetMetadata`.

</doc>

<doc path="go/claude-api/streaming.md">
```

````
# Streaming -- Go

## Streaming

```go
stream := client.Messages.NewStreaming(context.Background(), anthropic.MessageNewParams{
    Model:     anthropic.ModelClaudeOpus4_8,
    MaxTokens: 64000,
    Messages: []anthropic.MessageParam{
        anthropic.NewUserMessage(anthropic.NewTextBlock("Write a haiku")),
    },
})

for stream.Next() {
    event := stream.Current()
    switch eventVariant := event.AsAny().(type) {
    case anthropic.ContentBlockDeltaEvent:
        switch deltaVariant := eventVariant.Delta.AsAny().(type) {
        case anthropic.TextDelta:
            fmt.Print(deltaVariant.Text)
        }
    }
}
if err := stream.Err(); err != nil {
    log.Fatal(err)
}
```

**Accumulating the final message** (there is no `GetFinalMessage()` on the stream):

```go
stream := client.Messages.NewStreaming(ctx, params)
message := anthropic.Message{}
for stream.Next() {
    message.Accumulate(stream.Current())
}
if err := stream.Err(); err != nil { log.Fatal(err) }
// message.Content now has the complete response
```

<doc path="go/claude-api/tool-use.md">
# Tool Use -- Go

For conceptual overview (tool definitions, tool choice, tips), see
[shared/tool-use-concepts.md](../../shared/tool-use-concepts.md).

## Tool Use

### Tool Runner (Beta -- Recommended)

**Beta:** The Go SDK provides `BetaToolRunner` for automatic tool use loops via the `toolrunner` package.

```go
import (
    "context"
    "fmt"
    "log"

    "github.com/anthropics/anthropic-sdk-go"
    "github.com/anthropics/anthropic-sdk-go/toolrunner"
)

// Define tool input with jsonschema tags for automatic schema generation
type GetWeatherInput struct {
    City string `json:"city" jsonschema:"required,description=The city name"`
}
````
````

```
// Create a tool with automatic schema generation from struct tags
weatherTool, err := toolrunner.NewBetaToolFromJSONSchema(
    "get_weather",
    "Get current weather for a city",
    func(ctx context.Context, input GetWeatherInput) (anthropic.BetaToolResultBlockParamContentUnion, error) {
        return anthropic.BetaToolResultBlockParamContentUnion{
            OfText: &anthropic.BetaTextBlockParam{
                Text: fmt.Sprintf("The weather in %s is sunny, 72degF", input.City),
            },
        }, nil
    },
)
if err != nil {
    log.Fatal(err)
}

// Create a tool runner that handles the conversation loop automatically
runner := client.Beta.Messages.NewToolRunner(
    []anthropic.BetaTool{weatherTool},
    anthropic.BetaToolRunnerParams{
        BetaMessageNewParams: anthropic.BetaMessageNewParams{
            Model:     anthropic.ModelClaudeOpus4_8,
            MaxTokens: 16000,
            Messages: []anthropic.BetaMessageParam{
                anthropic.NewBetaUserMessage(anthropic.NewBetaTextBlock("What's the weather in Paris?")),
            },
        },
        MaxIterations: 5,
    },
)

// Run until Claude produces a final response
message, err := runner.RunToCompletion(context.Background())
if err != nil {
    log.Fatal(err)
}

// RunToCompletion returns *BetaMessage; content is []BetaContentBlockUnion.
// Narrow via AsAny() switch -- note the Beta-namespace types (BetaTextBlock,
// not TextBlock):
for _, block := range message.Content {
    switch block := block.AsAny().(type) {
    case anthropic.BetaTextBlock:
        fmt.Println(block.Text)
    }
}
```

Key features of the Go tool runner:

- Automatic schema generation from Go structs via `jsonschema` tags
- `RunToCompletion()` for simple one-shot usage
- `All()` iterator for processing each message in the conversation
- `NextMessage()` for step-by-step iteration
- Streaming variant via `NewToolRunnerStreaming()` with `AllStreaming()`

Manual Loop

Prefer the tool runner above. For interception, validation, logging, or human-in-the-loop approval, gate inside the tool's run function or step the runner with `NextMessage()`/`All()` and inspect each message (the runner's public `Params` field lets you adjust the next request) -- a manual loop is not required. Drop to a manual loop only when you need control the runner does not expose: define tools with `ToolParam`, check `StopReason`, execute tools yourself, and feed `tool_result` blocks back.

Derived from `anthropic-sdk-go/examples/tools/main.go`.

```go
package main
```

```
import (
    "context"
    "encoding/json"
    "fmt"
    "log"

    "github.com/anthropics/anthropic-sdk-go"
)

func main() {
    client := anthropic.NewClient()

    // 1. Define tools. ToolParam.InputSchema uses a map, no struct tags needed.
    addTool := anthropic.ToolParam{
        Name:        "add",
        Description: anthropic.String("Add two integers"),
        InputSchema: anthropic.ToolInputSchemaParam{
            Properties: map[string]any{
                "a": map[string]any{"type": "integer"},
                "b": map[string]any{"type": "integer"},
            },
        },
    }
    // ToolParam must be wrapped in ToolUnionParam for the Tools slice
    tools := []anthropic.ToolUnionParam{{OfTool: &addTool}}

    messages := []anthropic.MessageParam{
        anthropic.NewUserMessage(anthropic.NewTextBlock("What is 2 + 3?")),
    }

    for {
        resp, err := client.Messages.New(context.Background(), anthropic.MessageNewParams{
            Model:     anthropic.ModelClaudeSonnet4_6,
            MaxTokens: 16000,
            Messages:  messages,
            Tools:     tools,
        })
        if err != nil {
            log.Fatal(err)
        }

        // 2. Append the assistant response to history BEFORE processing tool calls.
        //    resp.ToParam() converts Message -> MessageParam in one call.
        messages = append(messages, resp.ToParam())

        // 3. Walk content blocks. ContentBlockUnion is a flattened struct;
        //    use block.AsAny().(type) to switch on the actual variant.
        toolResults := []anthropic.ContentBlockParamUnion{}
        for _, block := range resp.Content {
            switch variant := block.AsAny().(type) {
            case anthropic.TextBlock:
                fmt.Println(variant.Text)
            case anthropic.ToolUseBlock:
                // 4. Parse the tool input. Use variant.JSON.Input.Raw() to get the
                //    raw JSON -- block.Input is json.RawMessage, not the parsed value.
                var in struct {
                    A int `json:"a"`
                    B int `json:"b"`
                }
                if err := json.Unmarshal([]byte(variant.JSON.Input.Raw()), &in); err != nil {
                    log.Fatal(err)
                }
                result := fmt.Sprintf("%d", in.A+in.B)
                // 5. NewToolResultBlock(toolUseID, content, isError) builds the
                //    ContentBlockParamUnion for you. block.ID is the tool_use_id.
                toolResults = append(toolResults,
                    anthropic.NewToolResultBlock(block.ID, result, false))
            }
        }
```

```
        // 6. Exit when Claude stops asking for tools
        if resp.StopReason != anthropic.StopReasonToolUse {
            break
        }

        // 7. Tool results go in a user message (variadic: all results in one turn)
        messages = append(messages, anthropic.NewUserMessage(toolResults...))
    }
}
```

Key API surface:

Symbol	Purpose
`resp.ToParam()`	Convert `Message` response -> `MessageParam` for history
`block.AsAny().(type)`	Type-switch on `ContentBlockUnion` variants
`variant.JSON.Input.Raw()`	Raw JSON string of tool input (for `json.Unmarshal`)
`anthropic.NewToolResultBlock(id, content, isError)`	Build `tool_result` block
`anthropic.NewUserMessage(blocks...)`	Wrap tool results as a user turn
`anthropic.StopReasonToolUse`	`StopReason` constant to check loop termination
`anthropic.ToolUnionParam{OfTool: &t}`	Wrap `ToolParam` in the union for `Tools:`

Anthropic-Defined Tools

Version-suffixed struct names with `Param` suffix. `Name`/`Type` are `constant.*` types -- zero value marshals correctly, so `{}` works. Wrap in `ToolUnionParam` with the matching `Of*` field. Web search and code execution are server-executed; bash and text editor are client-executed (you handle the `tool_use` locally -- see `shared/tool-use-concepts.md`).

```go
Tools: []anthropic.ToolUnionParam{
    {OfWebSearchTool20260209: &anthropic.WebSearchTool20260209Param{}},
    {OfBashTool20250124: &anthropic.ToolBash20250124Param{}},
    {OfTextEditor20250728: &anthropic.ToolTextEditor20250728Param{}},
    {OfCodeExecutionTool20260120: &anthropic.CodeExecutionTool20260120Param{}},
},
```

Also available: `WebFetchTool20260209Param`, `ToolSearchToolBm25_20251119Param`, `ToolSearchToolRegex20251119Param`. For the advisor and memory tools, use `BetaAdvisorTool20260301Param` / `BetaMemoryTool20250818Param` in the beta namespace on `client.Beta.Messages.New`.

Advisor tool (beta)

Server-side -- no tool_result round-trip. The advisor model must be >= the executor (top-level) model; invalid pairs return 400.

```go
response, err := client.Beta.Messages.New(ctx, anthropic.BetaMessageNewParams{
    Model:     anthropic.ModelClaudeSonnet4_6,
    MaxTokens: 4096,
    Tools: []anthropic.BetaToolUnionParam{
        {OfAdvisorTool20260301: &anthropic.BetaAdvisorTool20260301Param{
            Model: anthropic.ModelClaudeOpus4_8,
        }},
    },
    Messages: []anthropic.BetaMessageParam{ /* ... */ },
    Betas:    []anthropic.AnthropicBeta{anthropic.AnthropicBetaAdvisorTool2026_03_01},
})
```

</doc>

<doc path="go/managed-agents/README.md">
Managed Agents -- Go

```
> **Bindings not shown here:** This README covers the most common managed-agents flows for Go. If you need a
class, method, namespace, field, or behavior that isn't shown, WebFetch the Go SDK repo **or the relevant
docs page** from `shared/live-sources.md` rather than guess. Do not extrapolate from cURL shapes or another
language's SDK.

> **Agents are persistent -- create once, reference by ID.** Store the agent ID returned by `agents.New` and
pass it to every subsequent `sessions.New`; do not call `agents.New` in the request path. **Recommended:**
define agents and environments as version-controlled YAML applied with the `ant` CLI -- see
`shared/anthropic-cli.md` (its live-docs URL is in `shared/live-sources.md`). The CLI owns the control plane
(create/update); your code owns the data plane (sessions with the stored ID). The examples below show in-code
creation for when you must provision programmatically; in production the create call belongs in setup, not in
the request path.

## Installation

```bash
go get github.com/anthropics/anthropic-sdk-go
```

Client Initialization

```go
import (
    "context"

    "github.com/anthropics/anthropic-sdk-go"
    "github.com/anthropics/anthropic-sdk-go/option"
)

// Default (uses ANTHROPIC_API_KEY env var)
client := anthropic.NewClient()

// Explicit API key
client := anthropic.NewClient(
    option.WithAPIKey("your-api-key"),
)

ctx := context.Background()
```

Create an Environment

```go
environment, err := client.Beta.Environments.New(ctx, anthropic.BetaEnvironmentNewParams{
    Name: "my-dev-env",
    Config: anthropic.BetaEnvironmentNewParamsConfigUnion{
        OfCloud: &anthropic.BetaCloudConfigParams{
            Networking: anthropic.BetaCloudConfigParamsNetworkingUnion{
                OfUnrestricted: &anthropic.BetaUnrestrictedNetworkParam{},
            },
        },
    },
})
if err != nil {
    panic(err)
}
fmt.Println(environment.ID) // env_...
```

Create an Agent (required first step)

> ?? **There is no inline agent config.** `Model`/`System`/`Tools` live on the agent object, not the session.
Always start with `Beta.Agents.New()` -- the session only takes `Agent:
anthropic.BetaSessionNewParamsAgentUnion{OfString: anthropic.String(agent.ID)}` (or the typed
`OfBetaManagedAgentsAgents` variant when you need a specific version).
```

Minimal

```go
// 1. Create the agent (reusable, versioned)
agent, err := client.Beta.Agents.New(ctx, anthropic.BetaAgentNewParams{
    Name: "Coding Assistant",
    Model: anthropic.BetaManagedAgentsModelConfigParams{
        ID:   "claude-opus-5",
        Type: anthropic.BetaManagedAgentsModelConfigParamsTypeModelConfig,
    },
    System: anthropic.String("You are a helpful coding assistant."),
    Tools: []anthropic.BetaAgentNewParamsToolUnion{{
        OfAgentToolset20260401: &anthropic.BetaManagedAgentsAgentToolset20260401Params{
            Type: anthropic.BetaManagedAgentsAgentToolset20260401ParamsTypeAgentToolset20260401,
        },
    }},
})
if err != nil {
    panic(err)
}

// 2. Start a session
session, err := client.Beta.Sessions.New(ctx, anthropic.BetaSessionNewParams{
    Agent: anthropic.BetaSessionNewParamsAgentUnion{
        OfBetaManagedAgentsAgents: &anthropic.BetaManagedAgentsAgentParams{
            Type:    anthropic.BetaManagedAgentsAgentParamsTypeAgent,
            ID:      agent.ID,
            Version: anthropic.Int(agent.Version),
        },
    },
    EnvironmentID: environment.ID,
    Title:         anthropic.String("Quickstart session"),
})
if err != nil {
    panic(err)
}
fmt.Printf("Session ID: %s, status: %s\n", session.ID, session.Status)
fmt.Printf("Trace: https://platform.claude.com/workspaces/default/sessions/%s\n", session.ID) // swap
'default' for your workspace ID if the API key is not in the Default workspace
```

Updating an Agent

Updates create new versions; the agent object is immutable per version.

```go
updatedAgent, err := client.Beta.Agents.Update(ctx, agent.ID, anthropic.BetaAgentUpdateParams{
    Version: agent.Version,
    System:  anthropic.String("You are a helpful coding agent. Always write tests."),
})
if err != nil {
    panic(err)
}
fmt.Printf("New version: %d\n", updatedAgent.Version)

// List all versions
iter := client.Beta.Agents.Versions.ListAutoPaging(ctx, agent.ID, anthropic.BetaAgentVersionListParams{})
for iter.Next() {
    version := iter.Current()
    fmt.Printf("Version %d: %s\n", version.Version, version.UpdatedAt.Format(time.RFC3339))
}
if err := iter.Err(); err != nil {
    panic(err)
}

// Archive the agent
_, err = client.Beta.Agents.Archive(ctx, agent.ID, anthropic.BetaAgentArchiveParams{})
if err != nil {
    panic(err)
}
```

```

---

## Send a User Message

```go
_, err = client.Beta.Sessions.Events.Send(ctx, session.ID, anthropic.BetaSessionEventSendParams{
    Events: []anthropic.BetaManagedAgentsEventParamsUnion{{
        OfUserMessage: &anthropic.BetaManagedAgentsUserMessageEventParams{
            Type: anthropic.BetaManagedAgentsUserMessageEventParamsTypeUserMessage,
            Content: []anthropic.BetaManagedAgentsUserMessageEventParamsContentUnion{{
                OfText: &anthropic.BetaManagedAgentsTextBlockParam{
                    Type: anthropic.BetaManagedAgentsTextBlockTypeText,
                    Text: "Review the auth module",
                },
            }},
        },
    }},
})
if err != nil {
    panic(err)
}
```

> ? **Stream-first:** Open the stream *before* (or concurrently with) sending the message. The stream only delivers events that occur after it opens -- stream-after-send means early events arrive buffered in one batch. See [Steering Patterns](../../shared/managed-agents-events.md#steering-patterns).

Stream Events (SSE)

```go
// Open the stream first, then send the user message
stream := client.Beta.Sessions.Events.StreamEvents(ctx, session.ID, anthropic.BetaSessionEventStreamParams{})
defer stream.Close()

if _, err := client.Beta.Sessions.Events.Send(ctx, session.ID, anthropic.BetaSessionEventSendParams{
    Events: []anthropic.BetaManagedAgentsEventParamsUnion{{
        OfUserMessage: &anthropic.BetaManagedAgentsUserMessageEventParams{
            Type: anthropic.BetaManagedAgentsUserMessageEventParamsTypeUserMessage,
            Content: []anthropic.BetaManagedAgentsUserMessageEventParamsContentUnion{{
                OfText: &anthropic.BetaManagedAgentsTextBlockParam{
                    Type: anthropic.BetaManagedAgentsTextBlockTypeText,
                    Text: "Summarize the repo README",
                },
            }},
        },
    }},
}); err != nil {
    panic(err)
}

events:
for stream.Next() {
    switch event := stream.Current().AsAny().(type) {
    case anthropic.BetaManagedAgentsAgentMessageEvent:
        for _, block := range event.Content {
            fmt.Print(block.Text)
        }
    case anthropic.BetaManagedAgentsAgentToolUseEvent:
        fmt.Printf("\n[Using tool: %s]\n", event.Name)
    case anthropic.BetaManagedAgentsSessionStatusIdleEvent:
        break events
    case anthropic.BetaManagedAgentsSessionErrorEvent:
        fmt.Printf("\n[Error: %s]\n", event.Error.Message)
        break events
    }
}
```
```

```
if err := stream.Err(); err != nil {
    panic(err)
}
```

Reconnecting and Tailing

When reconnecting mid-session, list past events first to dedupe, then tail live events:

```go
stream := client.Beta.Sessions.Events.StreamEvents(ctx, session.ID, anthropic.BetaSessionEventStreamParams{})
defer stream.Close()

// Stream is open and buffering. List history before tailing live.
seenEventIDs := map[string]struct{}{}
history := client.Beta.Sessions.Events.ListAutoPaging(ctx, session.ID, anthropic.BetaSessionEventListParams{})
for history.Next() {
    seenEventIDs[history.Current().ID] = struct{}{}
}
if err := history.Err(); err != nil {
    panic(err)
}

// Tail live events, skipping anything already seen
tail:
for stream.Next() {
    event := stream.Current()
    if _, seen := seenEventIDs[event.ID]; seen {
        continue
    }
    seenEventIDs[event.ID] = struct{}{}
    switch event := event.AsAny().(type) {
    case anthropic.BetaManagedAgentsAgentMessageEvent:
        for _, block := range event.Content {
            fmt.Print(block.Text)
        }
    case anthropic.BetaManagedAgentsSessionStatusIdleEvent:
        break tail
    }
}
if err := stream.Err(); err != nil {
    panic(err)
}
```

Provide Custom Tool Result

> ?? The Go managed-agents bindings for `user.custom_tool_result` are not yet documented in this skill or in the apps source examples. Refer to `shared/managed-agents-events.md` for the wire format and the `github.com/anthropics/anthropic-sdk-go` repository for the corresponding Go params types.

Poll Events

```go
// Auto-paginating iterator
iter := client.Beta.Sessions.Events.ListAutoPaging(ctx, session.ID, anthropic.BetaSessionEventListParams{})
for iter.Next() {
    event := iter.Current()
    fmt.Printf("%s: %s\n", event.Type, event.ID)
}
if err := iter.Err(); err != nil {
    panic(err)
}
```

```
## Upload a File

```go
csvFile, err := os.Open("data.csv")
if err != nil {
    panic(err)
}
defer csvFile.Close()

file, err := client.Beta.Files.Upload(ctx, anthropic.BetaFileUploadParams{
    File: csvFile,
})
if err != nil {
    panic(err)
}
fmt.Printf("File ID: %s\n", file.ID)

// Mount in a session
session, err := client.Beta.Sessions.New(ctx, anthropic.BetaSessionNewParams{
    Agent: anthropic.BetaSessionNewParamsAgentUnion{
        OfString: anthropic.String(agent.ID),
    },
    EnvironmentID: environment.ID,
    Resources: []anthropic.BetaSessionNewParamsResourceUnion{{
        OfFile: &anthropic.BetaManagedAgentsFileResourceParams{
            Type:      anthropic.BetaManagedAgentsFileResourceParamsTypeFile,
            FileID:    file.ID,
            MountPath: anthropic.String("/workspace/data.csv"),
        },
    }},
})
if err != nil {
    panic(err)
}
```

Add and Manage Resources on an Existing Session

```go
// Attach an additional file to an open session
resource, err := client.Beta.Sessions.Resources.Add(ctx, session.ID, anthropic.BetaSessionResourceAddParams{
    BetaManagedAgentsFileResourceParams: anthropic.BetaManagedAgentsFileResourceParams{
        Type:   anthropic.BetaManagedAgentsFileResourceParamsTypeFile,
        FileID: file.ID,
    },
})
if err != nil {
    panic(err)
}
fmt.Println(resource.ID) // "sesrsc_01ABC..."

// List resources on the session
listed, err := client.Beta.Sessions.Resources.List(ctx, session.ID, anthropic.BetaSessionResourceListParams{})
if err != nil {
    panic(err)
}
for _, entry := range listed.Data {
    fmt.Println(entry.ID, entry.Type)
}

// Detach a resource
if _, err := client.Beta.Sessions.Resources.Delete(ctx, resource.ID,
anthropic.BetaSessionResourceDeleteParams{
    SessionID: session.ID,
}); err != nil {
    panic(err)
}
```
```

````
---

## List and Download Session Files

> ?? Listing and downloading files an agent wrote during a session is not yet documented for Go in this skill
or in the apps source examples. See `shared/managed-agents-events.md` and the
`github.com/anthropics/anthropic-sdk-go` repository for the `Beta.Files.List` and `Beta.Files.Download` Go
params types.

---

## Session Management

```go
// List environments
environments, err := client.Beta.Environments.List(ctx, anthropic.BetaEnvironmentListParams{})
if err != nil {
    panic(err)
}

// Retrieve a specific environment
env, err := client.Beta.Environments.Get(ctx, environment.ID, anthropic.BetaEnvironmentGetParams{})
if err != nil {
    panic(err)
}

// Archive an environment (read-only, existing sessions continue)
_, err = client.Beta.Environments.Archive(ctx, environment.ID, anthropic.BetaEnvironmentArchiveParams{})
if err != nil {
    panic(err)
}

// Delete an environment (only if no sessions reference it)
_, err = client.Beta.Environments.Delete(ctx, environment.ID, anthropic.BetaEnvironmentDeleteParams{})
if err != nil {
    panic(err)
}

// Delete a session
_, err = client.Beta.Sessions.Delete(ctx, session.ID, anthropic.BetaSessionDeleteParams{})
if err != nil {
    panic(err)
}
```

---

## MCP Server Integration

```go
// Agent declares MCP server (no auth here -- auth goes in a vault)
agent, err := client.Beta.Agents.New(ctx, anthropic.BetaAgentNewParams{
    Name: "GitHub Assistant",
    Model: anthropic.BetaManagedAgentsModelConfigParams{
        ID:   "claude-opus-5",
        Type: anthropic.BetaManagedAgentsModelConfigParamsTypeModelConfig,
    },
    MCPServers: []anthropic.BetaManagedAgentsURLMCPServerParams{{
        Type: anthropic.BetaManagedAgentsURLMCPServerParamsTypeURL,
        Name: "github",
        URL:  "https://api.githubcopilot.com/mcp/",
    }},
    Tools: []anthropic.BetaAgentNewParamsToolUnion{
        {
            OfAgentToolset20260401: &anthropic.BetaManagedAgentsAgentToolset20260401Params{
                Type: anthropic.BetaManagedAgentsAgentToolset20260401ParamsTypeAgentToolset20260401,
            },
        },
        {
            OfMCPToolset: &anthropic.BetaManagedAgentsMCPToolsetParams{
````
````

```
                Type:          anthropic.BetaManagedAgentsMCPToolsetParamsTypeMCPToolset,
                MCPServerName: "github",
            },
        },
    },
})
if err != nil {
    panic(err)
}

// Session attaches vault(s) containing credentials for those MCP server URLs
session, err := client.Beta.Sessions.New(ctx, anthropic.BetaSessionNewParams{
    Agent: anthropic.BetaSessionNewParamsAgentUnion{
        OfBetaManagedAgentsAgents: &anthropic.BetaManagedAgentsAgentParams{
            Type:    anthropic.BetaManagedAgentsAgentParamsTypeAgent,
            ID:      agent.ID,
            Version: anthropic.Int(agent.Version),
        },
    },
    EnvironmentID: environment.ID,
    VaultIDs:      []string{vault.ID},
})
if err != nil {
    panic(err)
}
```

See `shared/managed-agents-tools.md` ?Vaults for creating vaults and adding credentials.

Vaults

```go
// Create a vault
vault, err := client.Beta.Vaults.New(ctx, anthropic.BetaVaultNewParams{
    DisplayName: "Alice",
    Metadata:    map[string]string{"external_user_id": "usr_abc123"},
})
if err != nil {
    panic(err)
}

// Add an OAuth credential
credential, err := client.Beta.Vaults.Credentials.New(ctx, vault.ID, anthropic.BetaVaultCredentialNewParams{
    DisplayName: anthropic.String("Alice's Slack"),
    Auth: anthropic.BetaVaultCredentialNewParamsAuthUnion{
        OfMCPOAuth: &anthropic.BetaManagedAgentsMCPOAuthCreateParams{
            Type:         anthropic.BetaManagedAgentsMCPOAuthCreateParamsTypeMCPOAuth,
            MCPServerURL: "https://mcp.slack.com/mcp",
            AccessToken:  "xoxp-...",
            ExpiresAt:    anthropic.Time(time.Date(2026, time.April, 15, 0, 0, 0, 0, time.UTC)),
            Refresh: anthropic.BetaManagedAgentsMCPOAuthRefreshParams{
                TokenEndpoint: "https://slack.com/api/oauth.v2.access",
                ClientID:      "1234567890.0987654321",
                Scope:         anthropic.String("channels:read chat:write"),
                RefreshToken:  "xoxe-1-...",
                TokenEndpointAuth: anthropic.BetaManagedAgentsMCPOAuthRefreshParamsTokenEndpointAuthUnion{
                    OfClientSecretPost: &anthropic.BetaManagedAgentsTokenEndpointAuthPostParam{
                        Type:
anthropic.BetaManagedAgentsTokenEndpointAuthPostParamTypeClientSecretPost,
                        ClientSecret: "abc123...",
                    },
                },
            },
        },
    },
})
if err != nil {
    panic(err)
```

```
}

// Rotate the credential (e.g., after a token refresh)
_, err = client.Beta.Vaults.Credentials.Update(ctx, credential.ID, anthropic.BetaVaultCredentialUpdateParams{
    VaultID: vault.ID,
    Auth: anthropic.BetaVaultCredentialUpdateParamsAuthUnion{
        OfMCPOAuth: &anthropic.BetaManagedAgentsMCPOAuthUpdateParams{
            Type:        anthropic.BetaManagedAgentsMCPOAuthUpdateParamsTypeMCPOAuth,
            AccessToken: anthropic.String("xoxp-new-..."),
            ExpiresAt:   anthropic.Time(time.Date(2026, time.May, 15, 0, 0, 0, 0, time.UTC)),
            Refresh: anthropic.BetaManagedAgentsMCPOAuthRefreshUpdateParams{
                RefreshToken: anthropic.String("xoxe-1-new-..."),
            },
        },
    },
})
if err != nil {
    panic(err)
}

// Archive a vault
_, err = client.Beta.Vaults.Archive(ctx, vault.ID, anthropic.BetaVaultArchiveParams{})
if err != nil {
    panic(err)
}
```

GitHub Repository Integration

Mount a GitHub repository as a session resource (a vault holds the GitHub MCP credential):

```go
session, err := client.Beta.Sessions.New(ctx, anthropic.BetaSessionNewParams{
    Agent:         anthropic.BetaSessionNewParamsAgentUnion{OfString: anthropic.String(agent.ID)},
    EnvironmentID: environment.ID,
    VaultIDs:      []string{vault.ID},
    Resources: []anthropic.BetaSessionNewParamsResourceUnion{
        {
            OfGitHubRepository: &anthropic.BetaManagedAgentsGitHubRepositoryResourceParams{
                Type:
anthropic.BetaManagedAgentsGitHubRepositoryResourceParamsTypeGitHubRepository,
                URL:                "https://github.com/org/repo",
                MountPath:          anthropic.String("/workspace/repo"),
                AuthorizationToken: "ghp_your_github_token",
            },
        },
    },
})
if err != nil {
    panic(err)
}
```

Multiple repositories on the same session:

```go
resources := []anthropic.BetaSessionNewParamsResourceUnion{
    {
        OfGitHubRepository: &anthropic.BetaManagedAgentsGitHubRepositoryResourceParams{
            Type:               anthropic.BetaManagedAgentsGitHubRepositoryResourceParamsTypeGitHubRepository,
            URL:                "https://github.com/org/frontend",
            MountPath:          anthropic.String("/workspace/frontend"),
            AuthorizationToken: "ghp_your_github_token",
        },
    },
    {
        OfGitHubRepository: &anthropic.BetaManagedAgentsGitHubRepositoryResourceParams{
            Type:               anthropic.BetaManagedAgentsGitHubRepositoryResourceParamsTypeGitHubRepository,
```

```
            URL:                "https://github.com/org/backend",
            MountPath:          anthropic.String("/workspace/backend"),
            AuthorizationToken: "ghp_your_github_token",
        },
    },
}
```

Rotating a repository's authorization token:

```go
listed, err := client.Beta.Sessions.Resources.List(ctx, session.ID, anthropic.BetaSessionResourceListParams{})
if err != nil {
    panic(err)
}
repoResourceID := listed.Data[0].ID

_, err = client.Beta.Sessions.Resources.Update(ctx, repoResourceID, anthropic.BetaSessionResourceUpdateParams{
    SessionID:          session.ID,
    AuthorizationToken: "ghp_your_new_github_token",
})
if err != nil {
    panic(err)
}
```
</doc>

<doc path="java/claude-api/README.md">
Claude API -- Java

> **Note:** The Java SDK supports the Claude API and beta tool use with annotated classes. Agent SDK is not yet available for Java.

Package Reference

Types are organized by package. If a class you need isn't shown in an example below, locate it via this table first -- don't block on fetching SDK source over the network.

`import` prefix	Contains
`com.anthropic.client` / `com.anthropic.client.okhttp`	`AnthropicClient`, `AnthropicOkHttpClient`
`com.anthropic.models.messages`	non-beta request/response types -- `MessageCreateParams`, `Model`, `Message`, `TextBlockParam`, `ContentBlockParam`, `ToolUseBlockParam`, `ToolResultBlockParam`, `CacheControlEphemeral`, `Tool*` (e.g. `ToolBash20250124`, `ToolTextEditor20250728`), `StopReason`, `StructuredMessage*`
`com.anthropic.models.messages.batches`	Batch API -- `BatchResultsParams`, `MessageBatchIndividualResponse`
`com.anthropic.models.beta`	`AnthropicBeta` (beta-flag constants)
`com.anthropic.models.beta.messages`	beta-endpoint types -- `MessageCreateParams`, `BetaMessage`, `BetaStopReason`, `BetaContextManagementConfig`, `BetaMcpToolset`, `BetaRequestMcpServerUrlDefinition`, `BetaTool*`
`com.anthropic.core`	`JsonValue`, `JsonField`, `JsonSchemaLocalValidation`, `com.anthropic.core.http.StreamResponse`
`com.anthropic.errors`	typed exceptions -- `AnthropicServiceException`, `RateLimitException`, `NotFoundException`, etc. (see `shared/error-codes.md`)

`client.messages()` uses `com.anthropic.models.messages.*`; `client.beta().messages()` uses `com.anthropic.models.beta.messages.*`. Both packages define a `MessageCreateParams` -- import the one matching the client path you call.

Key types per feature

Write from this table instead of `javap`/jar inspection. Endpoint column tells you whether to use `client.messages()` or `client.beta().messages()`.

Feature	Endpoint	Key Java types / builder calls
User profiles	beta	`client.beta().userProfiles().create(...)` / `.retrieve(id)` / `.list()`. Pass the returned profile id on the beta `MessageCreateParams`. Requires a beta header -- check the SDK's beta-headers reference for the current flag.

```
| Agent Skills | beta | `BetaContainerParams`, `BetaSkillParams`, `BetaCodeExecutionTool20250825`.
`.addBeta("code-execution-2025-08-25").addBeta("skills-2025-10-02")`. Download the output via
`client.beta().files().download(fileId)`. |
| Cache diagnostics | beta | `BetaDiagnosticsParam`, `BetaCacheControlEphemeral` |
| Context editing | beta | `.contextManagement(BetaContextManagementConfig.builder()...)`. The edit strategy
is a `BetaClearToolUses20250919Edit` (or `BetaClearThinking20251015Edit`); its trigger is a
`BetaInputTokensTrigger` built separately and passed to the edit's builder -- there is no direct
`.inputTokensTrigger(N)` shortcut on the edit builder. `javap` the edit and trigger classes for the exact
setter names. |
| Memory tool | non-beta | `.addTool(MemoryTool20250818.builder().build())` from
`com.anthropic.models.messages` |
| Programmatic tool calling | non-beta | `CodeExecutionTool20260120`, `Tool`, `ContentBlockParam` |
| Strict tool use | non-beta | `Tool`, `Tool.InputSchema` |
| Task budgets | beta |
`.outputConfig(BetaOutputConfig.builder().taskBudget(BetaTokenTaskBudget.builder()...))` |
| Tool search | non-beta | `.addTool(ToolSearchToolRegex20251119.builder()...)` from
`com.anthropic.models.messages` |
| Web search | non-beta | `WebSearchTool20260209` from `com.anthropic.models.messages` -- the latest variant
with dynamic filtering (Claude Fable 5 + Claude Opus 5 + Opus 4.8/4.7/4.6 + Claude Sonnet 5 + Sonnet 4.6).
For older models or Vertex, use `WebSearchTool20250305` |

### Discovering type and member names

If a class or builder method you need isn't in the tables above, `jar tf <anthropic-java-core jar> | grep -i
<term>` or `javap -classpath <jar> com.anthropic.models....` is fast enough to locate names. **Do not compile
and run a separate reflection program** to enumerate members -- the first build is slow enough to be
backgrounded in many environments, trapping you in a polling loop. Write the script with the names you found
and let the compiler error (`cannot find symbol`) point at any wrong member.

## Installation

Maven:

```xml
<dependency>
    <groupId>com.anthropic</groupId>
    <artifactId>anthropic-java</artifactId>
    <version>2.34.0</version>
</dependency>
```

Gradle:

```groovy
implementation("com.anthropic:anthropic-java:2.34.0")
```

Client Initialization

```java
import com.anthropic.client.AnthropicClient;
import com.anthropic.client.okhttp.AnthropicOkHttpClient;

// Default (reads ANTHROPIC_API_KEY from environment)
AnthropicClient client = AnthropicOkHttpClient.fromEnv();

// Explicit API key
AnthropicClient client = AnthropicOkHttpClient.builder()
    .apiKey("your-api-key")
    .build();
```

Basic Message Request

```java
import com.anthropic.models.messages.MessageCreateParams;
import com.anthropic.models.messages.Message;
```
```

```
MessageCreateParams params = MessageCreateParams.builder()
    .model("claude-opus-5")  // .model(String) overload -- use it for ids with no typed Model constant yet
    .maxTokens(16000L)
    .addUserMessage("What is the capital of France?")
    .build();

Message response = client.messages().create(params);
response.content().stream()
    .flatMap(block -> block.text().stream())
    .forEach(textBlock -> System.out.println(textBlock.text()));
```

Thinking

Adaptive thinking is the recommended mode for Claude 4.6+ models. Claude decides dynamically when and how much to think. The builder has a direct `.thinking(ThinkingConfigAdaptive)` overload -- no manual union wrapping.

> **Fable 5, Claude Opus 5, Opus 4.8, Opus 4.7, Opus 4.6, and Sonnet 4.6:** Use adaptive thinking (below). `ThinkingConfigEnabled.builder().budgetTokens(N)` is removed on Fable 5, Claude Opus 5, Opus 4.8, and 4.7 (400 if sent); deprecated on Opus 4.6 and Sonnet 4.6.
> **Claude Opus 5:** thinking is on by default -- omitting `.thinking(...)` runs adaptive (`ThinkingConfigAdaptive` is equivalent), unlike Opus 4.8/4.7 where omitting it meant no thinking. `ThinkingConfigDisabled` is accepted only at effort `HIGH` or lower; pairing it with `XHIGH`/`MAX` returns a 400.
> **Older models:** Use `.thinking(ThinkingConfigEnabled.builder().budgetTokens(N).build())` (budget must be < `maxTokens`, min 1024).

```java
import com.anthropic.models.messages.ContentBlock;
import com.anthropic.models.messages.MessageCreateParams;
import com.anthropic.models.messages.Model;
import com.anthropic.models.messages.ThinkingConfigAdaptive;

MessageCreateParams params = MessageCreateParams.builder()
    .model(Model.CLAUDE_SONNET_4_6)
    .maxTokens(16000L)
    .thinking(ThinkingConfigAdaptive.builder().build())
    .addUserMessage("Solve this step by step: 27 * 453")
    .build();

for (ContentBlock block : client.messages().create(params).content()) {
    block.thinking().ifPresent(t -> System.out.println("[thinking] " + t.thinking()));
    block.text().ifPresent(t -> System.out.println(t.text()));
}
```

`ContentBlock` narrowing: `.thinking()` / `.text()` return `Optional<T>` -- use `.ifPresent(...)` or `.stream().flatMap(...)`. Alternative: `isThinking()` / `asThinking()` boolean+unwrap pairs (throws on wrong variant).

Effort Parameter

Effort is nested inside `OutputConfig` -- there is NO `.effort()` directly on `MessageCreateParams.Builder`.

```java
import com.anthropic.models.messages.OutputConfig;

.outputConfig(OutputConfig.builder()
    .effort(OutputConfig.Effort.HIGH)  // or LOW, MEDIUM, XHIGH, MAX
    .build())
```

Combine with `Thinking = ThinkingConfigAdaptive` for cost-quality control.

```
## Prompt Caching

System message as a list of `TextBlockParam` with `CacheControlEphemeral`. Use
`.systemOfTextBlockParams(...)` -- the plain `.system(String)` overload can't carry cache control. For
placement patterns and the silent-invalidator audit checklist, see `shared/prompt-caching.md`.

```java
import com.anthropic.models.messages.TextBlockParam;
import com.anthropic.models.messages.CacheControlEphemeral;

.systemOfTextBlockParams(List.of(
    TextBlockParam.builder()
        .text(longSystemPrompt)
        .cacheControl(CacheControlEphemeral.builder()
            .ttl(CacheControlEphemeral.Ttl.TTL_1H)  // optional; also TTL_5M
            .build())
        .build()))
```

There's also a top-level `.cacheControl(CacheControlEphemeral)` on `MessageCreateParams.Builder` and on
`Tool.builder()`.

Verify hits via `response.usage().cacheCreationInputTokens()` / `response.usage().cacheReadInputTokens()`.

Token Counting

```java
import com.anthropic.models.messages.MessageCountTokensParams;

long tokens = client.messages().countTokens(
    MessageCountTokensParams.builder()
        .model(Model.CLAUDE_SONNET_4_6)
        .addUserMessage("Hello")
        .build()
).inputTokens();
```

PDF / Document Input

`DocumentBlockParam` builder has source shortcuts. Wrap in `ContentBlockParam.ofDocument()` and pass via
`.addUserMessageOfBlockParams()`.

```java
import com.anthropic.models.messages.DocumentBlockParam;
import com.anthropic.models.messages.ContentBlockParam;
import com.anthropic.models.messages.TextBlockParam;

DocumentBlockParam doc = DocumentBlockParam.builder()
    .source(Base64PdfSource.builder().data(base64String).build())
    // or .source(UrlPdfSource.builder().url("https://...").build())
    .title("My Document")        // optional
    .build();
```

For **Files API** document references, use the beta path and beta types -- see `files-api.md`:
`BetaRequestDocumentBlock.builder().source(BetaFileDocumentSource.builder().fileId(id).build())`.

```java
.addUserMessageOfBlockParams(List.of(
    ContentBlockParam.ofDocument(doc),
    ContentBlockParam.ofText(TextBlockParam.builder().text("Summarize this").build())))
```

```

````
## Stop Details

When `stopReason()` is `"refusal"`, the response includes structured `stopDetails()`:

```java
response.stopDetails().ifPresent(details -> {
    System.out.println("Category: " + details.category());
    System.out.println("Explanation: " + details.explanation());
});
```

**Refusal fallbacks (Claude Fable 5) -- opt in by default.** Fallbacks are opt-in: without them a refused
request simply stops. New `claude-fable-5` code should include the server-side `fallbacks` parameter (beta
header `server-side-fallback-2026-06-01`, fallback model `claude-opus-4-8`, on the beta messages call) by
default. The exact Java builder methods (and the client-side middleware for providers without server-side
support) are not documented here -- WebFetch the Java SDK repo's `examples/` from `shared/live-sources.md`;
full semantics in `shared/model-migration.md` -> Migrating to Claude Fable 5 -> `refusal` stop reason.

---

## Error Type

`AnthropicServiceException` exposes `.errorType()` returning `Optional<ErrorType>` for programmatic error
classification:

```java
try {
    client.messages().create(params);
} catch (AnthropicServiceException e) {
    e.errorType().ifPresent(type ->
        System.out.println("Error type: " + type)  // RATE_LIMIT_ERROR, OVERLOADED_ERROR, etc.
    );
}
```

---
</doc>

<doc path="java/claude-api/files-api.md">
# Files API -- Java

## Files API (Beta)

Under `client.beta().files()`. File references in messages need the beta message types (non-beta
`DocumentBlockParam.Source` has no file-ID variant).

```java
import com.anthropic.models.beta.files.FileUploadParams;
import com.anthropic.models.beta.files.FileMetadata;
import com.anthropic.models.beta.messages.BetaRequestDocumentBlock;
import com.anthropic.models.beta.messages.BetaFileDocumentSource;
import java.nio.file.Paths;

FileMetadata meta = client.beta().files().upload(
    FileUploadParams.builder()
        .file(Paths.get("/path/to/doc.pdf"))  // or .file(InputStream) or .file(byte[])
        .build());

// Reference in a beta message:
BetaRequestDocumentBlock doc = BetaRequestDocumentBlock.builder()
    .source(BetaFileDocumentSource.builder().fileId(meta.id()).build())
    .build();
```

Other methods: `.list()`, `.delete(String fileId)`, `.download(String fileId)`, `.retrieveMetadata(String
fileId)`.
</doc>

<doc path="java/claude-api/tool-use.md">
# Tool Use -- Java

For conceptual overview (tool definitions, tool choice, tips), see
[shared/tool-use-concepts.md](../../shared/tool-use-concepts.md).

## Tool Use (Beta)

The Java SDK supports beta tool use with annotated classes. Tool classes implement `Supplier<String>` for
automatic execution via `BetaToolRunner`.

### Tool Runner (automatic loop)

```java
import com.anthropic.models.beta.messages.MessageCreateParams;
import com.anthropic.models.beta.messages.BetaMessage;
import com.anthropic.helpers.BetaToolRunner;
import com.fasterxml.jackson.annotation.JsonClassDescription;
import com.fasterxml.jackson.annotation.JsonPropertyDescription;
import java.util.function.Supplier;

@JsonClassDescription("Get the weather in a given location")
static class GetWeather implements Supplier<String> {
    @JsonPropertyDescription("The city and state, e.g. San Francisco, CA")
    public String location;

    @Override
    public String get() {
        return "The weather in " + location + " is sunny and 72degF";
    }
}

BetaToolRunner toolRunner = client.beta().messages().toolRunner(
    MessageCreateParams.builder()
        .model("claude-opus-5")
        .maxTokens(16000L)
        .putAdditionalHeader("anthropic-beta", "structured-outputs-2025-11-13")
        .addTool(GetWeather.class)
        .addUserMessage("What's the weather in San Francisco?")
        .build());

for (BetaMessage message : toolRunner) {
    System.out.println(message);
}
```
````

Memory Tool

The Java SDK provides `BetaMemoryToolHandler` for implementing the memory tool backend. You supply a handler that manages file storage, and the `BetaToolRunner` handles memory tool calls automatically.

```java
import com.anthropic.helpers.BetaMemoryToolHandler;
import com.anthropic.helpers.BetaToolRunner;
import com.anthropic.models.beta.messages.BetaMemoryTool20250818;
import com.anthropic.models.beta.messages.BetaMessage;
import com.anthropic.models.beta.messages.MessageCreateParams;
import com.anthropic.models.beta.messages.ToolRunnerCreateParams;

// Implement BetaMemoryToolHandler with your storage backend (e.g., filesystem)
BetaMemoryToolHandler memoryHandler = new FileSystemMemoryToolHandler(sandboxRoot);

MessageCreateParams createParams = MessageCreateParams.builder()
    .model("claude-opus-5")
    .maxTokens(4096L)
    .addTool(BetaMemoryTool20250818.builder().build())
    .addUserMessage("Remember that my favorite color is blue")
    .build();

BetaToolRunner toolRunner = client.beta().messages().toolRunner(
    ToolRunnerCreateParams.builder()
        .betaMemoryToolHandler(memoryHandler)
        .initialMessageParams(createParams)
        .build());

for (BetaMessage message : toolRunner) {
    System.out.println(message);
}
```

See the [shared memory tool concepts](../../shared/tool-use-concepts.md) for more details on the memory tool.

Non-Beta Tool Declaration (manual JSON schema)

`Tool.InputSchema.Properties` is a freeform `Map<String, JsonValue>` wrapper -- build property schemas via `putAdditionalProperty`. `type: "object"` is the default. The builder has a direct `.addTool(Tool)` overload that wraps in `ToolUnion` automatically.

```java
import com.anthropic.core.JsonValue;
import com.anthropic.models.messages.Tool;

Tool tool = Tool.builder()
    .name("get_weather")
    .description("Get the current weather in a given location")
    .inputSchema(Tool.InputSchema.builder()
        .properties(Tool.InputSchema.Properties.builder()
            .putAdditionalProperty("location", JsonValue.from(Map.of("type", "string")))
            .build())
        .required(List.of("location"))
        .build())
    .build();

MessageCreateParams params = MessageCreateParams.builder()
    .model(Model.CLAUDE_SONNET_4_6)
    .maxTokens(16000L)
    .addTool(tool)
    .addUserMessage("Weather in Paris?")
    .build();
```

For manual tool loops, handle `tool_use` blocks in the response, send `tool_result` back, loop until `stop_reason` is `"end_turn"`. See [shared tool use concepts](../../shared/tool-use-concepts.md).

Building `MessageParam` with Content Blocks (Tool Result Round-Trip)

`MessageParam.Content` is an inner union class (string | list). Use the builder's
`.contentOfBlockParams(List<ContentBlockParam>)` alias -- there is NO separate `MessageParamContent` class
with a static `ofBlockParams`:

```java
import com.anthropic.models.messages.MessageParam;
import com.anthropic.models.messages.ContentBlockParam;
import com.anthropic.models.messages.ToolResultBlockParam;

List<ContentBlockParam> results = List.of(
    ContentBlockParam.ofToolResult(ToolResultBlockParam.builder()
        .toolUseId(toolUseBlock.id())
        .content(yourResultString)
        .build())
);

MessageParam toolResultMsg = MessageParam.builder()
    .role(MessageParam.Role.USER)
    .contentOfBlockParams(results)   // builder alias for Content.ofBlockParams(...)
    .build();
```

Structured Output

The class-based overload auto-derives the JSON schema from your POJO and gives you a typed `.text()` return
-- no manual schema, no manual parsing.

```java
import com.anthropic.models.messages.StructuredMessageCreateParams;

record Book(String title, String author) {}
record BookList(List<Book> books) {}

StructuredMessageCreateParams<BookList> params = MessageCreateParams.builder()
    .model(Model.CLAUDE_SONNET_4_6)
    .maxTokens(16000L)
    .outputConfig(BookList.class)  // returns a typed builder
    .addUserMessage("List 3 classic novels")
    .build();

client.messages().create(params).content().stream()
    .flatMap(cb -> cb.text().stream())
    .forEach(typed -> {
        // typed.text() returns BookList, not String
        for (Book b : typed.text().books()) System.out.println(b.title());
    });
```

Supports Jackson annotations: `@JsonPropertyDescription`, `@JsonIgnore`, `@ArraySchema(minItems=...)`. Manual
schema path: `OutputConfig.builder().format(JsonOutputFormat.builder().schema(...).build())`.

Anthropic-Defined Tools

Version-suffixed types; `name`/`type` auto-set by builder. Direct `.addTool()` overloads exist for most tool
types; where one is missing (newer or less-common tools -- see the advisor note below), wrap via the union
type's static factory: `.addTool(BetaToolUnion.of<ToolName>(builder...build()))`. Web search and code
execution are server-executed; bash and text editor are client-executed (you handle the `tool_use` locally --
see `shared/tool-use-concepts.md`).

```java
import com.anthropic.models.messages.WebSearchTool20260209;
import com.anthropic.models.messages.ToolBash20250124;
import com.anthropic.models.messages.ToolTextEditor20250728;
import com.anthropic.models.messages.CodeExecutionTool20260120;

.addTool(WebSearchTool20260209.builder()
```

```
    .maxUses(5L)                              // optional
    .allowedDomains(List.of("example.com"))   // optional
    .build())
.addTool(ToolBash20250124.builder().build())
.addTool(ToolTextEditor20250728.builder().build())
.addTool(CodeExecutionTool20260120.builder().build())
```

Also available: `WebFetchTool20260209`, `MemoryTool20250818`, `ToolSearchToolBm25_20251119`. For the advisor tool, use `BetaAdvisorTool20260301` in the beta namespace with `.addBeta("advisor-tool-2026-03-01")` (server-side; advisor model >= executor model). There is no direct `.addTool(BetaAdvisorTool20260301)` overload on the beta builder -- wrap it via the `BetaToolUnion` static factory for the advisor type; if `javac` rejects the specific factory method name, `javap com.anthropic.models.beta.messages.BetaToolUnion | grep -i advisor` shows the exact one.

Beta namespace (MCP, compaction)

For beta-only features use `com.anthropic.models.beta.messages.*` -- class names have a `Beta` prefix AND live in the beta package. The beta `MessageCreateParams.Builder` has direct `.addTool(BetaToolBash20250124)` overloads AND `.addMcpServer()`:

```java
import com.anthropic.models.beta.messages.MessageCreateParams;
import com.anthropic.models.beta.messages.BetaToolBash20250124;
import com.anthropic.models.beta.messages.BetaCodeExecutionTool20260120;
import com.anthropic.models.beta.messages.BetaRequestMcpServerUrlDefinition;

MessageCreateParams params = MessageCreateParams.builder()
    .model(Model.CLAUDE_OPUS_4_8)
    .maxTokens(16000L)
    .addBeta("mcp-client-2025-11-20")
    .addTool(BetaToolBash20250124.builder().build())
    .addTool(BetaCodeExecutionTool20260120.builder().build())
    .addMcpServer(BetaRequestMcpServerUrlDefinition.builder()
        .name("my-server")
        .url("https://example.com/mcp")
        .build())
    .addUserMessage("...")
    .build();

client.beta().messages().create(params);
```

`BetaTool*` types are NOT interchangeable with non-beta `Tool*` -- pick one namespace per request.

Reading server-tool blocks in the response: `ServerToolUseBlock` has `.id()`, `.name()` (enum), and `._input()` returning raw `JsonValue` -- there is NO typed `.input()`. For code execution results, unwrap two levels:

```java
for (ContentBlock block : response.content()) {
    block.serverToolUse().ifPresent(stu -> {
        System.out.println("tool: " + stu.name() + " input: " + stu._input());
    });
    block.codeExecutionToolResult().ifPresent(r -> {
        r.content().resultBlock().ifPresent(result -> {
            System.out.println("stdout: " + result.stdout());
            System.out.println("stderr: " + result.stderr());
            System.out.println("exit: " + result.returnCode());
        });
    });
}
```

</doc>

<doc path="java/managed-agents/README.md">
Managed Agents -- Java

```
> **Bindings not shown here:** This README covers the most common managed-agents flows for Java. If you need
a class, method, namespace, field, or behavior that isn't shown, WebFetch the Java SDK repo **or the relevant
docs page** from `shared/live-sources.md` rather than guess. Do not extrapolate from cURL shapes or another
language's SDK.

> **Agents are persistent -- create once, reference by ID.** Store the agent ID returned by
`client.beta().agents().create` and pass it to every subsequent `client.beta().sessions().create`; do not
call `agents().create` in the request path. **Recommended:** define agents and environments as
version-controlled YAML applied with the `ant` CLI -- see `shared/anthropic-cli.md` (its live-docs URL is in
`shared/live-sources.md`). The CLI owns the control plane (create/update); your code owns the data plane
(sessions with the stored ID). The examples below show in-code creation for when you must provision
programmatically; in production the create call belongs in setup, not in the request path.

## Installation

```xml
<dependency>
    <groupId>com.anthropic</groupId>
    <artifactId>anthropic-java</artifactId>
</dependency>
```

Client Initialization

```java
import com.anthropic.client.okhttp.AnthropicOkHttpClient;

// Default (uses ANTHROPIC_API_KEY env var)
var client = AnthropicOkHttpClient.fromEnv();
```

Create an Environment

```java
import com.anthropic.models.beta.environments.BetaCloudConfigParams;
import com.anthropic.models.beta.environments.BetaUnrestrictedNetwork;
import com.anthropic.models.beta.environments.EnvironmentCreateParams;

var environment = client.beta().environments().create(EnvironmentCreateParams.builder()
    .name("my-dev-env")
    .config(BetaCloudConfigParams.builder()
        .networking(BetaUnrestrictedNetwork.builder().build())
        .build())
    .build());
System.out.println("Environment ID: " + environment.id()); // env_...
```

Create an Agent (required first step)

> ?? **There is no inline agent config.** Model, system, and tools live on the agent object, not the session.
Always start with `client.beta().agents().create()` -- the session takes either `.agent(agent.id())` or the
typed `BetaManagedAgentsAgentParams.builder()...build()`.

Minimal

```java
import com.anthropic.models.beta.agents.AgentCreateParams;
import com.anthropic.models.beta.agents.BetaManagedAgentsAgentToolset20260401Params;
import com.anthropic.models.beta.sessions.BetaManagedAgentsAgentParams;
import com.anthropic.models.beta.sessions.SessionCreateParams;

// 1. Create the agent (reusable, versioned)
var agent = client.beta().agents().create(AgentCreateParams.builder()
    .name("Coding Assistant")
    .model("claude-opus-5")
    .system("You are a helpful coding assistant.")
```
```

```
    .addTool(BetaManagedAgentsAgentToolset20260401Params.builder()
        .type(BetaManagedAgentsAgentToolset20260401Params.Type.AGENT_TOOLSET_20260401)
        .build())
    .build());

// 2. Start a session
var session = client.beta().sessions().create(SessionCreateParams.builder()
    .agent(BetaManagedAgentsAgentParams.builder()
        .type(BetaManagedAgentsAgentParams.Type.AGENT)
        .id(agent.id())
        .version(agent.version())
        .build())
    .environmentId(environment.id())
    .title("Quickstart session")
    .build());
System.out.println("Session ID: " + session.id());
System.out.println("Trace: https://platform.claude.com/workspaces/default/sessions/" + session.id()); // swap
'default' for your workspace ID if the API key is not in the Default workspace
```

Updating an Agent

Updates create new versions; the agent object is immutable per version.

```java
import com.anthropic.models.beta.agents.AgentUpdateParams;

var updatedAgent = client.beta().agents().update(agent.id(), AgentUpdateParams.builder()
    .version(agent.version())
    .system("You are a helpful coding agent. Always write tests.")
    .build());
System.out.println("New version: " + updatedAgent.version());

// List all versions
for (var version : client.beta().agents().versions().list(agent.id()).autoPager()) {
    System.out.println("Version " + version.version() + ": " + version.updatedAt());
}

// Archive the agent
var archived = client.beta().agents().archive(agent.id());
System.out.println("Archived at: " + archived.archivedAt().orElseThrow());
```

Send a User Message

```java
import com.anthropic.models.beta.sessions.events.BetaManagedAgentsUserMessageEventParams;
import com.anthropic.models.beta.sessions.events.EventSendParams;

client.beta().sessions().events().send(session.id(), EventSendParams.builder()
    .addEvent(BetaManagedAgentsUserMessageEventParams.builder()
        .type(BetaManagedAgentsUserMessageEventParams.Type.USER_MESSAGE)
        .addTextContent("Review the auth module")
        .build())
    .build());
```

> ? **Stream-first:** Open the stream *before* (or concurrently with) sending the message. The stream only
delivers events that occur after it opens -- stream-after-send means early events arrive buffered in one
batch. See [Steering Patterns](../../shared/managed-agents-events.md#steering-patterns).

Stream Events (SSE)

```java
import com.anthropic.models.beta.sessions.events.StreamEvents;
```

```
// Open the stream first, then send the user message
try (var stream = client.beta().sessions().events().streamStreaming(session.id())) {
    client.beta().sessions().events().send(session.id(), EventSendParams.builder()
        .addEvent(BetaManagedAgentsUserMessageEventParams.builder()
            .type(BetaManagedAgentsUserMessageEventParams.Type.USER_MESSAGE)
            .addTextContent("Summarize the repo README")
            .build())
        .build());

    for (var event : (Iterable<StreamEvents>) stream.stream()::iterator) {
        if (event.isAgentMessage()) {
            event.asAgentMessage().content().forEach(block -> System.out.print(block.text()));
        } else if (event.isAgentToolUse()) {
            System.out.println("\n[Using tool: " + event.asAgentToolUse().name() + "]");
        } else if (event.isSessionStatusIdle()) {
            break;
        } else if (event.isSessionError()) {
            System.out.println("\n[Error]");
            break;
        }
    }
}
```

Reconnecting and Tailing

When reconnecting mid-session, list past events first to dedupe, then tail live events. The cross-variant `id` field is read from the raw `_json()` value:

```java
import com.anthropic.core.JsonValue;
import java.util.HashSet;
import java.util.Map;
import java.util.Optional;

try (var stream = client.beta().sessions().events().streamStreaming(session.id())) {
    // Stream is open and buffering. List history before tailing live.
    var seenEventIds = new HashSet<String>();
    for (var past : client.beta().sessions().events().list(session.id()).autoPager()) {
        Optional<Map<String, JsonValue>> obj = past._json().orElseThrow().asObject();
        seenEventIds.add(obj.orElseThrow().get("id").asStringOrThrow());
    }

    // Tail live events, skipping anything already seen
    for (var event : (Iterable<StreamEvents>) stream.stream()::iterator) {
        Optional<Map<String, JsonValue>> obj = event._json().orElseThrow().asObject();
        if (!seenEventIds.add(obj.orElseThrow().get("id").asStringOrThrow())) continue;
        if (event.isAgentMessage()) {
            event.asAgentMessage().content().forEach(block -> System.out.print(block.text()));
        } else if (event.isSessionStatusIdle()) {
            break;
        }
    }
}
```

Provide Custom Tool Result

> ?? The Java managed-agents bindings for `user.custom_tool_result` are not yet documented in this skill or in the apps source examples. Refer to `shared/managed-agents-events.md` for the wire format and the `anthropic-java` repository for the corresponding params types.

Poll Events

```java
for (var event : client.beta().sessions().events().list(session.id()).autoPager()) {
```

```
    System.out.println(event.type() + ": " + event);
}
```

Upload a File

```java
import com.anthropic.models.beta.files.FileUploadParams;
import com.anthropic.models.beta.sessions.BetaManagedAgentsFileResourceParams;
import java.nio.file.Path;

var dataCsv = Path.of("data.csv");

var file = client.beta().files().upload(FileUploadParams.builder()
    .file(dataCsv)
    .build());
System.out.println("File ID: " + file.id());

// Mount in a session
var session = client.beta().sessions().create(SessionCreateParams.builder()
    .agent(agent.id())
    .environmentId(environment.id())
    .addResource(BetaManagedAgentsFileResourceParams.builder()
        .type(BetaManagedAgentsFileResourceParams.Type.FILE)
        .fileId(file.id())
        .mountPath("/workspace/data.csv")
        .build())
    .build());
```

Add and Manage Resources on an Existing Session

```java
import com.anthropic.models.beta.sessions.resources.ResourceAddParams;
import com.anthropic.models.beta.sessions.resources.ResourceDeleteParams;

// Attach an additional file to an open session
var resource = client.beta().sessions().resources().add(session.id(), ResourceAddParams.builder()
    .betaManagedAgentsFileResourceParams(BetaManagedAgentsFileResourceParams.builder()
        .type(BetaManagedAgentsFileResourceParams.Type.FILE)
        .fileId(file.id())
        .build())
    .build());
System.out.println(resource.id()); // "sesrsc_01ABC..."

// List resources on the session -- entries are a discriminated union
var listed = client.beta().sessions().resources().list(session.id());
for (var entry : listed.data()) {
    if (entry.isFile()) {
        var fileResource = entry.asFile();
        System.out.println(fileResource.id() + " " + fileResource.type());
    } else if (entry.isGitHubRepository()) {
        var repoResource = entry.asGitHubRepository();
        System.out.println(repoResource.id() + " " + repoResource.type());
    }
}

// Detach a resource
client.beta().sessions().resources().delete(resource.id(), ResourceDeleteParams.builder()
    .sessionId(session.id())
    .build());
```

List and Download Session Files

> ?? Listing and downloading files an agent wrote during a session is not yet documented for Java in this

````
skill or in the apps source examples. See `shared/managed-agents-events.md` and the `anthropic-java`
repository for the file list/download bindings.

---

## Session Management

```java
// List environments
var environments = client.beta().environments().list();

// Retrieve a specific environment
var env = client.beta().environments().retrieve(environment.id());

// Archive an environment (read-only, existing sessions continue)
client.beta().environments().archive(environment.id());

// Delete an environment (only if no sessions reference it)
client.beta().environments().delete(environment.id());

// Delete a session
client.beta().sessions().delete(session.id());
```

---

## MCP Server Integration

```java
import com.anthropic.models.beta.agents.BetaManagedAgentsMcpToolsetParams;
import com.anthropic.models.beta.agents.BetaManagedAgentsUrlMcpServerParams;

// Agent declares MCP server (no auth here -- auth goes in a vault)
var agent = client.beta().agents().create(AgentCreateParams.builder()
    .name("GitHub Assistant")
    .model("claude-opus-5")
    .addMcpServer(BetaManagedAgentsUrlMcpServerParams.builder()
        .type(BetaManagedAgentsUrlMcpServerParams.Type.URL)
        .name("github")
        .url("https://api.githubcopilot.com/mcp/")
        .build())
    .addTool(BetaManagedAgentsAgentToolset20260401Params.builder()
        .type(BetaManagedAgentsAgentToolset20260401Params.Type.AGENT_TOOLSET_20260401)
        .build())
    .addTool(BetaManagedAgentsMcpToolsetParams.builder()
        .type(BetaManagedAgentsMcpToolsetParams.Type.MCP_TOOLSET)
        .mcpServerName("github")
        .build())
    .build());

// Session attaches vault(s) containing credentials for those MCP server URLs
var session = client.beta().sessions().create(SessionCreateParams.builder()
    .agent(BetaManagedAgentsAgentParams.builder()
        .type(BetaManagedAgentsAgentParams.Type.AGENT)
        .id(agent.id())
        .version(agent.version())
        .build())
    .environmentId(environment.id())
    .addVaultId(vault.id())
    .build());
```

See `shared/managed-agents-tools.md` ?Vaults for creating vaults and adding credentials.

---

## Vaults

```java
import com.anthropic.core.JsonValue;
````
````

```
import com.anthropic.models.beta.vaults.VaultCreateParams;
import com.anthropic.models.beta.vaults.credentials.BetaManagedAgentsMcpOAuthCreateParams;
import com.anthropic.models.beta.vaults.credentials.BetaManagedAgentsMcpOAuthRefreshParams;
import com.anthropic.models.beta.vaults.credentials.BetaManagedAgentsMcpOAuthRefreshUpdateParams;
import com.anthropic.models.beta.vaults.credentials.BetaManagedAgentsMcpOAuthUpdateParams;
import com.anthropic.models.beta.vaults.credentials.CredentialCreateParams;
import com.anthropic.models.beta.vaults.credentials.CredentialUpdateParams;
import java.time.OffsetDateTime;

// Create a vault
var vault = client.beta().vaults().create(VaultCreateParams.builder()
    .displayName("Alice")
    .metadata(VaultCreateParams.Metadata.builder()
        .putAdditionalProperty("external_user_id", JsonValue.from("usr_abc123"))
        .build())
    .build());
System.out.println(vault.id()); // "vlt_01ABC..."

// Add an OAuth credential
var credential = client.beta().vaults().credentials().create(vault.id(),
    CredentialCreateParams.builder()
        .displayName("Alice's Slack")
        .auth(BetaManagedAgentsMcpOAuthCreateParams.builder()
            .type(BetaManagedAgentsMcpOAuthCreateParams.Type.MCP_OAUTH)
            .mcpServerUrl("https://mcp.slack.com/mcp")
            .accessToken("xoxp-...")
            .expiresAt(OffsetDateTime.parse("2026-04-15T00:00:00Z"))
            .refresh(BetaManagedAgentsMcpOAuthRefreshParams.builder()
                .tokenEndpoint("https://slack.com/api/oauth.v2.access")
                .clientId("1234567890.0987654321")
                .scope("channels:read chat:write")
                .refreshToken("xoxe-1-...")
                .clientSecretPostTokenEndpointAuth("abc123...")
                .build())
            .build())
        .build());

// Rotate the credential (e.g., after a token refresh)
client.beta().vaults().credentials().update(credential.id(),
    CredentialUpdateParams.builder()
        .vaultId(vault.id())
        .auth(BetaManagedAgentsMcpOAuthUpdateParams.builder()
            .type(BetaManagedAgentsMcpOAuthUpdateParams.Type.MCP_OAUTH)
            .accessToken("xoxp-new-...")
            .expiresAt(OffsetDateTime.parse("2026-05-15T00:00:00Z"))
            .refresh(BetaManagedAgentsMcpOAuthRefreshUpdateParams.builder()
                .refreshToken("xoxe-1-new-...")
                .build())
            .build())
        .build());

// Archive a vault
client.beta().vaults().archive(vault.id());
```

GitHub Repository Integration

Mount a GitHub repository as a session resource (a vault holds the GitHub MCP credential):

```java
import com.anthropic.models.beta.sessions.BetaManagedAgentsGitHubRepositoryResourceParams;

var session = client.beta().sessions().create(SessionCreateParams.builder()
    .agent(agent.id())
    .environmentId(environment.id())
    .addVaultId(vault.id())
    .addResource(BetaManagedAgentsGitHubRepositoryResourceParams.builder()
        .type(BetaManagedAgentsGitHubRepositoryResourceParams.Type.GITHUB_REPOSITORY)
```

```
        .url("https://github.com/org/repo")
        .mountPath("/workspace/repo")
        .authorizationToken("ghp_your_github_token")
        .build())
    .build());
```

Multiple repositories on the same session:

```java
import java.util.List;

var resources = List.of(
    BetaManagedAgentsGitHubRepositoryResourceParams.builder()
        .type(BetaManagedAgentsGitHubRepositoryResourceParams.Type.GITHUB_REPOSITORY)
        .url("https://github.com/org/frontend")
        .mountPath("/workspace/frontend")
        .authorizationToken("ghp_your_github_token")
        .build(),
    BetaManagedAgentsGitHubRepositoryResourceParams.builder()
        .type(BetaManagedAgentsGitHubRepositoryResourceParams.Type.GITHUB_REPOSITORY)
        .url("https://github.com/org/backend")
        .mountPath("/workspace/backend")
        .authorizationToken("ghp_your_github_token")
        .build());
```

Rotating a repository's authorization token:

```java
import com.anthropic.models.beta.sessions.resources.ResourceUpdateParams;

var listed = client.beta().sessions().resources().list(session.id());
var repoResourceId = listed.data().get(0).asGitHubRepository().id();

client.beta().sessions().resources().update(repoResourceId, ResourceUpdateParams.builder()
    .sessionId(session.id())
    .authorizationToken("ghp_your_new_github_token")
    .build());
```
</doc>

<doc path="php/claude-api/README.md">
Claude API -- PHP

> **Note:** The PHP SDK is the official Anthropic SDK for PHP. A beta tool runner is available via `$client->beta->messages->toolRunner()`. Structured output helpers are supported via `StructuredOutputModel` classes. Agent SDK is not available. Bedrock, Vertex AI, and Foundry clients are supported.

Installation

```bash
composer require "anthropic-ai/sdk"
```

Client Initialization

```php
use Anthropic\Client;

// Using API key from environment variable
$client = new Client(apiKey: getenv("ANTHROPIC_API_KEY"));
```

Amazon Bedrock

```php
use Anthropic\Bedrock\MantleClient;

// Messages-API Bedrock endpoint. Reads AWS credentials from env.
```

```
$client = new MantleClient(awsRegion: 'us-east-1');
```

Model IDs on Bedrock take an `anthropic.` prefix -- e.g. `model: 'anthropic.claude-opus-5'`.

Google Vertex AI

```php
use Anthropic\Vertex;

// Constructor is private. Parameter is `location`, not `region`.
$client = Vertex\Client::fromEnvironment(
    location: 'us-east5',
    projectId: 'my-project-id',
);
```

Anthropic Foundry

```php
use Anthropic\Foundry;

// Constructor is private. baseUrl or resource is required.
$client = Foundry\Client::withCredentials(
    apiKey: getenv('ANTHROPIC_FOUNDRY_API_KEY'),
    baseUrl: 'https://<resource>.services.ai.azure.com/anthropic/v1',
);
```

Basic Message Request

```php
$message = $client->messages->create(
    model: 'claude-opus-5',
    maxTokens: 16000,
    messages: [
        ['role' => 'user', 'content' => 'What is the capital of France?'],
    ],
);

// content is an array of polymorphic blocks (TextBlock, ToolUseBlock,
// ThinkingBlock). Accessing ->text on content[0] without checking the block
// type will throw if the first block is not a TextBlock (e.g., when extended
// thinking is enabled and a ThinkingBlock comes first). Always guard:
foreach ($message->content as $block) {
    if ($block->type === 'text') {
        echo $block->text;
    }
}
```

If you only want the first text block:

```php
foreach ($message->content as $block) {
    if ($block->type === 'text') {
        echo $block->text;
        break;
    }
}
```

Extended Thinking

Adaptive thinking is the recommended mode for Claude 4.6+ models. Claude decides dynamically when and how much to think.

```php
use Anthropic\Messages\ThinkingBlock;

$message = $client->messages->create(
    model: 'claude-opus-5',
    maxTokens: 16000,
    thinking: ['type' => 'adaptive', 'display' => 'summarized'], // display opt-in: default is omitted (empty
thinking text) on Fable 5 / Mythos 5 / Claude Opus 5 / Opus 4.8 / 4.7
    messages: [
        ['role' => 'user', 'content' => 'Solve: 27 * 453'],
    ],
);

// ThinkingBlock(s) precede TextBlock in content
foreach ($message->content as $block) {
    if ($block instanceof ThinkingBlock) {
        echo "Thinking:\n{$block->thinking}\n\n";
        // $block->signature is an opaque string -- preserve verbatim if
        // passing thinking blocks back in multi-turn conversations
    } elseif ($block->type === 'text') {
        echo "Answer: {$block->text}\n";
    }
}
```

> **Fable 5, Claude Opus 5, Opus 4.8, Opus 4.7, Opus 4.6, and Sonnet 4.6:** Use adaptive thinking (above).
`['type' => 'enabled', 'budgetTokens' => N]` is removed on Fable 5, Claude Opus 5, Opus 4.8, and 4.7 (400 if
sent); deprecated on Opus 4.6 and Sonnet 4.6.
> **Claude Opus 5:** thinking is on by default -- omitting `thinking:` runs adaptive (`['type' =>
'adaptive']` is equivalent), unlike Opus 4.8/4.7 where omitting it meant no thinking. `['type' =>
'disabled']` is accepted only at effort `high` or lower; pairing it with `xhigh`/`max` returns a 400.
> **Older models:** Use `thinking: ['type' => 'enabled', 'budgetTokens' => N]` (budget must be < `maxTokens`,
min 1024).

`$block->type === 'thinking'` also works for the check; `instanceof` narrows for PHPStan.

Prompt Caching

`system:` takes an array of text blocks; set `cacheControl` on the last block. Array-shape syntax (camelCase
keys) is idiomatic. For placement patterns and the silent-invalidator audit checklist, see
`shared/prompt-caching.md`.

```php
$message = $client->messages->create(
    model: 'claude-opus-5',
    maxTokens: 16000,
    system: [
        ['type' => 'text', 'text' => $longSystemPrompt, 'cacheControl' => ['type' => 'ephemeral']],
    ],
    messages: [['role' => 'user', 'content' => 'Summarize the key points']],
);
```

For 1-hour TTL: `'cacheControl' => ['type' => 'ephemeral', 'ttl' => '1h']`. There's also a top-level
`cacheControl:` on `messages->create(...)` that auto-places on the last cacheable block.

Verify hits via `$message->usage->cacheCreationInputTokens` / `$message->usage->cacheReadInputTokens`.

Stop Details

When `stopReason` is `'refusal'`, the response includes structured `stopDetails`:

```php
if ($message->stopReason === 'refusal' && $message->stopDetails !== null) {
    echo "Category: " . $message->stopDetails->category . "\n";     // e.g. "cyber", "bio",
```

````
"reasoning_extraction", "frontier_llm", or null -- see docs for the full set
    echo "Explanation: " . $message->stopDetails->explanation . "\n";
}
```

**Refusal fallbacks (Claude Fable 5) -- opt in by default.** Fallbacks are opt-in: without them a refused request simply stops. New `claude-fable-5` code should include the server-side `fallbacks` parameter (beta header `server-side-fallback-2026-06-01`, fallback model `claude-opus-4-8`, on the beta messages call) by default. The exact PHP binding (and the client-side middleware for providers without server-side support) is not documented here -- WebFetch the PHP SDK repo's `examples/` from `shared/live-sources.md`; full semantics in `shared/model-migration.md` -> Migrating to Claude Fable 5 -> `refusal` stop reason.

---

## Error Type

`APIStatusException` exposes a `->type` property for programmatic error classification:

```php
try {
    $client->messages->create(...);
} catch (\Anthropic\Core\Exceptions\APIStatusException $e) {
    echo $e->type?->value;  // "rate_limit_error", "overloaded_error", etc.
}
```
</doc>

<doc path="php/claude-api/batches.md">
# Message Batches -- PHP

## Message Batches API

```php
$batch = $client->messages->batches->create(requests: [
    ['customId' => 'req-1', 'params' => ['model' => 'claude-opus-5', 'maxTokens' => 1024, 'messages' =>
[...]]],
    ['customId' => 'req-2', 'params' => [...]],
]);
// Poll $client->messages->batches->retrieve($batch->id) until processingStatus === 'ended',
// then iterate $client->messages->batches->results($batch->id).
```

# Streaming -- PHP

## Streaming

> **Requires SDK v0.5.0+.** v0.4.0 and earlier used a single `$params` array; calling with named parameters throws `Unknown named parameter $model`. Upgrade: `composer require "anthropic-ai/sdk:^0.7"`

```php
use Anthropic\Messages\RawContentBlockDeltaEvent;
use Anthropic\Messages\TextDelta;
````

```
$stream = $client->messages->createStream(
    model: 'claude-opus-5',
    maxTokens: 64000,
    messages: [
        ['role' => 'user', 'content' => 'Write a haiku'],
    ],
);

foreach ($stream as $event) {
    if ($event instanceof RawContentBlockDeltaEvent && $event->delta instanceof TextDelta) {
        echo $event->delta->text;
    }
}
```

</doc>

<doc path="php/claude-api/tool-use.md">
Tool Use -- PHP

For conceptual overview (tool definitions, tool choice, tips), see
[shared/tool-use-concepts.md](../../shared/tool-use-concepts.md).

Tool Use

Tool Runner (Beta)

Beta: The PHP SDK provides a tool runner via `$client->beta->messages->toolRunner()`. Define tools with
`BetaRunnableTool` -- a definition array plus a `run` closure:

```php
use Anthropic\Lib\Tools\BetaRunnableTool;

$weatherTool = new BetaRunnableTool(
    definition: [
        'name' => 'get_weather',
        'description' => 'Get the current weather for a location.',
        'inputSchema' => [
            'type' => 'object',
            'properties' => [
                'location' => ['type' => 'string', 'description' => 'City and state'],
            ],
            'required' => ['location'],
        ],
    ],
    run: function (array $input): string {
        return "The weather in {$input['location']} is sunny and 72degF.";
    },
);

$runner = $client->beta->messages->toolRunner(
    maxTokens: 16000,
    messages: [['role' => 'user', 'content' => 'What is the weather in Paris?']],
    model: 'claude-opus-5',
    tools: [$weatherTool],
);

foreach ($runner as $message) {
    foreach ($message->content as $block) {
        if ($block->type === 'text') {
            echo $block->text;
        }
    }
}
```

Manual Loop

````
Tools are passed as arrays. **The SDK uses camelCase keys** (`inputSchema`, `toolUseID`, `stopReason`) and
auto-maps to the API's snake_case on the wire -- since v0.5.0. See [shared tool use
concepts](../../shared/tool-use-concepts.md) for the loop pattern.

```php
use Anthropic\Messages\ToolUseBlock;

$tools = [
    [
        'name' => 'get_weather',
        'description' => 'Get the current weather in a given location',
        'inputSchema' => [  // camelCase, not input_schema
            'type' => 'object',
            'properties' => [
                'location' => ['type' => 'string', 'description' => 'City and state'],
            ],
            'required' => ['location'],
        ],
    ],
];

$messages = [['role' => 'user', 'content' => 'What is the weather in SF?']];

$response = $client->messages->create(
    model: 'claude-opus-5',
    maxTokens: 16000,
    tools: $tools,
    messages: $messages,
);

while ($response->stopReason === 'tool_use') {  // camelCase property
    $toolResults = [];
    foreach ($response->content as $block) {
        if ($block instanceof ToolUseBlock) {
            // $block->name  : string               -- tool name to dispatch on
            // $block->input : array<string,mixed>  -- parsed JSON input
            // $block->id    : string               -- pass back as toolUseID
            $result = executeYourTool($block->name, $block->input);
            $toolResults[] = [
                'type' => 'tool_result',
                'toolUseID' => $block->id,  // camelCase, not tool_use_id
                'content' => $result,
            ];
        }
    }

    // Append assistant turn + user turn with tool results
    $messages[] = ['role' => 'assistant', 'content' => $response->content];
    $messages[] = ['role' => 'user', 'content' => $toolResults];

    $response = $client->messages->create(
        model: 'claude-opus-5',
        maxTokens: 16000,
        tools: $tools,
        messages: $messages,
    );
}

// Final text response
foreach ($response->content as $block) {
    if ($block->type === 'text') {
        echo $block->text;
    }
}
```

`$block->type === 'tool_use'` also works; `instanceof ToolUseBlock` narrows for PHPStan.

---
````

```
## Structured Outputs

### Using StructuredOutputModel (Recommended)

Define a PHP class implementing `StructuredOutputModel` and pass it as `outputConfig`:

```php
use Anthropic\Lib\Contracts\StructuredOutputModel;
use Anthropic\Lib\Concerns\StructuredOutputModelTrait;
use Anthropic\Lib\Attributes\Constrained;

class Person implements StructuredOutputModel
{
    use StructuredOutputModelTrait;

    #[Constrained(description: 'Full name')]
    public string $name;

    public int $age;

    public ?string $email = null;  // nullable = optional field
}

$message = $client->messages->create(
    model: 'claude-opus-5',
    maxTokens: 16000,
    messages: [['role' => 'user', 'content' => 'Generate a profile for Alice, age 30']],
    outputConfig: ['format' => Person::class],
);

$person = $message->parsedOutput();  // Person instance
echo $person->name;
```

Types are inferred from PHP type hints. Use `#[Constrained(description: '...')]` to add descriptions.
Nullable properties (`?string`) become optional fields.

Raw Schema

```php
$message = $client->messages->create(
    model: 'claude-opus-5',
    maxTokens: 16000,
    messages: [['role' => 'user', 'content' => 'Extract: John (john@co.com), Enterprise plan']],
    outputConfig: [
        'format' => [
            'type' => 'json_schema',
            'schema' => [
                'type' => 'object',
                'properties' => [
                    'name' => ['type' => 'string'],
                    'email' => ['type' => 'string'],
                    'plan' => ['type' => 'string'],
                ],
                'required' => ['name', 'email', 'plan'],
                'additionalProperties' => false,
            ],
        ],
    ],
);

// First text block contains valid JSON
foreach ($message->content as $block) {
    if ($block->type === 'text') {
        $data = json_decode($block->text, true);
        break;
    }
}
```
```

````
---

## Beta Features & Anthropic-Defined Tools

**`betas:` is NOT a param on `$client->messages->create()`** -- it only exists on the beta namespace. Use it
for features that need an explicit opt-in header:

```php
use Anthropic\Beta\Messages\BetaRequestMCPServerURLDefinition;

$response = $client->beta->messages->create(
    model: 'claude-opus-5',
    maxTokens: 16000,
    mcpServers: [
        BetaRequestMCPServerURLDefinition::with(
            name: 'my-server',
            url: 'https://example.com/mcp',
        ),
    ],
    betas: ['mcp-client-2025-11-20'],  // only valid on ->beta->messages
    messages: [['role' => 'user', 'content' => 'Use the MCP tools']],
);
```

### Task budgets

```php
$response = $client->beta->messages->create(
    model: 'claude-opus-5',
    maxTokens: 16000,
    outputConfig: ['taskBudget' => ['type' => 'tokens', 'total' => 64000]],
    tools: [...],
    messages: [...],
    betas: ['task-budgets-2026-03-13'],
);
```

### Cache diagnostics

Pass the previous response's `id` on the next request; print the `diagnostics` object on the response:

```php
$r2 = $client->beta->messages->create(
    model: 'claude-opus-5', maxTokens: 1024,
    diagnostics: ['previousMessageId' => $r1->id],
    betas: ['cache-diagnosis-2026-04-07'],
    messages: [...],
);
```

**Anthropic-defined tools** (bash, web_search, text_editor, code_execution) are GA and work on both paths. Of
these, web_search and code_execution are server-executed; bash and text_editor are client-executed (you
handle the `tool_use` locally) -- `Anthropic\Messages\ToolBash20250124` / `WebSearchTool20260209` /
`ToolTextEditor20250728` / `CodeExecutionTool20260120` for non-beta,
`Anthropic\Beta\Messages\BetaToolBash20250124` / `BetaWebSearchTool20260209` / `BetaToolTextEditor20250728` /
`BetaCodeExecutionTool20260120` for beta. No `betas:` header needed for these.

### Tool search (non-beta, server-side)

```php
tools: [
    ['type' => 'tool_search_tool_regex_20251119', 'name' => 'tool_search_tool_regex'],
    ['name' => 'get_weather', 'description' => '...', 'inputSchema' => [...], 'deferLoading' => true],
    // ... other user tools with 'deferLoading' => true
],
```

### Memory tool (non-beta, client-executed)
````

````
Declare `['type' => 'memory_20250818', 'name' => 'memory']`. Handle the `tool_use` by reading/writing files
under a fixed `/memories` directory. **Validate every model-supplied path**: resolve to its canonical form
and verify it remains within the memory directory; reject traversal (`..`, symlinks) -- see
`shared/tool-use-concepts.md` ? Client-Side Tools.

---
</doc>

<doc path="php/managed-agents/README.md">
# Managed Agents -- PHP

> **Bindings not shown here:** This README covers the most common managed-agents flows for PHP. If you need a
class, method, namespace, field, or behavior that isn't shown, WebFetch the PHP SDK repo **or the relevant
docs page** from `shared/live-sources.md` rather than guess. Do not extrapolate from cURL shapes or another
language's SDK.

> **Agents are persistent -- create once, reference by ID.** Store the agent ID returned by
`$client->beta->agents->create` and pass it to every subsequent `->sessions->create`; do not call
`agents->create` in the request path. **Recommended:** define agents and environments as version-controlled
YAML applied with the `ant` CLI -- see `shared/anthropic-cli.md` (its live-docs URL is in
`shared/live-sources.md`). The CLI owns the control plane (create/update); your code owns the data plane
(sessions with the stored ID). The examples below show in-code creation for when you must provision
programmatically; in production the create call belongs in setup, not in the request path.

## Installation

```bash
composer require "anthropic-ai/sdk" "guzzlehttp/guzzle:^7"
```

## Client Initialization

```php
use Anthropic\Client;

// Default (uses ANTHROPIC_API_KEY env var)
$client = new Client();

// Explicit API key
$client = new Client(apiKey: 'your-api-key');
```

---

## Create an Environment

```php
$environment = $client->beta->environments->create(
    name: 'my-dev-env',
    config: ['type' => 'cloud', 'networking' => ['type' => 'unrestricted']],
);
echo "Environment ID: {$environment->id}\n"; // env_...
```

---

## Create an Agent (required first step)

> ?? **There is no inline agent config.** `model`/`system`/`tools` live on the agent object, not the session.
Always start with `$client->beta->agents->create()` -- the session takes either `agent: $agent->id` or the
typed `BetaManagedAgentsAgentParams::with(type: 'agent', id: $agent->id, version: $agent->version)`.

### Minimal

```php
use Anthropic\Beta\Agents\BetaManagedAgentsAgentToolset20260401Params;

// 1. Create the agent (reusable, versioned)
$agent = $client->beta->agents->create(
    name: 'Coding Assistant',
````
````

```
    model: 'claude-opus-5',
    system: 'You are a helpful coding assistant.',
    tools: [
        BetaManagedAgentsAgentToolset20260401Params::with(
            type: 'agent_toolset_20260401',
        ),
    ],
);

// 2. Start a session
$session = $client->beta->sessions->create(
    agent: ['type' => 'agent', 'id' => $agent->id, 'version' => $agent->version],
    environmentID: $environment->id,
    title: 'Quickstart session',
);
echo "Session ID: {$session->id}\n";
echo "Trace: https://platform.claude.com/workspaces/default/sessions/{$session->id}\n"; // swap 'default' for
your workspace ID if the API key is not in the Default workspace
```

Updating an Agent

Updates create new versions; the agent object is immutable per version.

```php
$updatedAgent = $client->beta->agents->update(
    $agent->id,
    version: $agent->version,
    system: 'You are a helpful coding agent. Always write tests.',
);
echo "New version: {$updatedAgent->version}\n";

// List all versions
foreach ($client->beta->agents->versions->list($agent->id)->pagingEachItem() as $version) {
    echo "Version {$version->version}: {$version->updatedAt->format(DateTimeInterface::ATOM)}\n";
}

// Archive the agent
$archived = $client->beta->agents->archive($agent->id);
echo "Archived at: {$archived->archivedAt->format(DateTimeInterface::ATOM)}\n";
```

Send a User Message

```php
$client->beta->sessions->events->send(
    $session->id,
    events: [
        [
            'type' => 'user.message',
            'content' => [['type' => 'text', 'text' => 'Review the auth module']],
        ],
    ],
);
```

> ? **Stream-first:** Open the stream *before* (or concurrently with) sending the message. The stream only
delivers events that occur after it opens -- stream-after-send means early events arrive buffered in one
batch. See [Steering Patterns](../../shared/managed-agents-events.md#steering-patterns).

Stream Events (SSE)

> ?? **Streaming transporter:** PHP's default buffered PSR-18 client never returns for the open-ended session
event stream. Use a streaming Guzzle transporter for `streamStream()` calls -- other calls keep the default
client.

```php
$streamingClient = new GuzzleHttp\Client(['stream' => true]);

// Open the stream first, then send the user message
$stream = $client->beta->sessions->events->streamStream(
    $session->id,
    requestOptions: ['transporter' => $streamingClient],
);
$client->beta->sessions->events->send(
    $session->id,
    events: [
        [
            'type' => 'user.message',
            'content' => [['type' => 'text', 'text' => 'Summarize the repo README']],
        ],
    ],
);

foreach ($stream as $event) {
    match ($event->type) {
        'agent.message' => array_walk(
            $event->content,
            static fn($block) => $block->type === 'text' ? print($block->text) : null,
        ),
        'agent.tool_use' => print("\n[Using tool: {$event->name}]\n"),
        'session.error' => printf("\n[Error: %s]", $event->error?->message ?? 'unknown'),
        default => null,
    };
    if ($event->type === 'session.status_idle' || $event->type === 'session.error') {
        break;
    }
}
$stream->close();
```

Reconnecting and Tailing

When reconnecting mid-session, list past events first to dedupe, then tail live events:

```php
$stream = $client->beta->sessions->events->streamStream(
    $session->id,
    requestOptions: ['transporter' => $streamingClient],
);

// Stream is open and buffering. List history before tailing live.
$seenEventIds = [];
foreach ($client->beta->sessions->events->list($session->id)->pagingEachItem() as $event) {
    $seenEventIds[$event->id] = true;
}

// Tail live events, skipping anything already seen
foreach ($stream as $event) {
    if (isset($seenEventIds[$event->id])) {
        continue;
    }
    $seenEventIds[$event->id] = true;
    match ($event->type) {
        'agent.message' => array_walk(
            $event->content,
            static fn($block) => $block->type === 'text' ? print($block->text) : null,
        ),
        default => null,
    };
    if ($event->type === 'session.status_idle') {
        break;
    }
}
$stream->close();
```

````
---

## Provide Custom Tool Result

> ?? The PHP managed-agents bindings for `user.custom_tool_result` are not yet documented in this skill or in
the apps source examples. Refer to `shared/managed-agents-events.md` for the wire format and the
`anthropic-ai/sdk` PHP repository for the corresponding params.

---

## Poll Events

```php
foreach ($client->beta->sessions->events->list($session->id)->pagingEachItem() as $event) {
    echo "{$event->type}: {$event->id}\n";
}
```

---

## Upload a File

> ?? **PHP file upload:** The PHP SDK's beta managed-agents file upload binding is not shown in the apps
source examples; the canonical PHP example uses raw cURL against `POST /v1/files`. If your codebase prefers
the SDK, WebFetch the `anthropic-ai/sdk` PHP repository for the latest binding before writing code.

```php
use Anthropic\Beta\Sessions\BetaManagedAgentsFileResourceParams;

// Raw cURL upload (canonical example from the apps source)
$csvPath = 'data.csv';
$ch = curl_init('https://api.anthropic.com/v1/files');
curl_setopt_array($ch, [
    CURLOPT_RETURNTRANSFER => true,
    CURLOPT_POST => true,
    CURLOPT_HTTPHEADER => [
        'x-api-key: ' . getenv('ANTHROPIC_API_KEY'),
        'anthropic-version: 2023-06-01',
        'anthropic-beta: files-api-2025-04-14',
    ],
    CURLOPT_POSTFIELDS => ['file' => new CURLFile($csvPath, 'text/csv', 'data.csv')],
]);
$file = json_decode(curl_exec($ch));
echo "File ID: {$file->id}\n";

// Mount in a session
$session = $client->beta->sessions->create(
    agent: $agent->id,
    environmentID: $environment->id,
    resources: [
        BetaManagedAgentsFileResourceParams::with(
            type: 'file',
            fileID: $file->id,
            mountPath: '/workspace/data.csv',
        ),
    ],
);
```

### Add and Manage Resources on an Existing Session

```php
// Attach an additional file to an open session
$resource = $client->beta->sessions->resources->add(
    $session->id,
    type: 'file',
    fileID: $file->id,
);
echo "{$resource->id}\n"; // "sesrsc_01ABC..."
````
````

```
// List resources on the session
$listed = $client->beta->sessions->resources->list($session->id);
foreach ($listed->data as $entry) {
    echo "{$entry->id} {$entry->type}\n";
}

// Detach a resource
$client->beta->sessions->resources->delete($resource->id, sessionID: $session->id);
```

List and Download Session Files

```php
$files = $client->beta->files->list(
    scopeID: 'sesn_abc123',
    betas: ['managed-agents-2026-04-01'],
);
$content = $client->beta->files->download($files->data[0]->id);
file_put_contents('output.txt', $content);
```

Session Management

```php
// List environments
$environments = $client->beta->environments->list();

// Retrieve a specific environment
$env = $client->beta->environments->retrieve($environment->id);

// Archive an environment (read-only, existing sessions continue)
$client->beta->environments->archive($environment->id);

// Delete an environment (only if no sessions reference it)
$client->beta->environments->delete($environment->id);

// Delete a session
$client->beta->sessions->delete($session->id);
```

MCP Server Integration

```php
use Anthropic\Beta\Agents\BetaManagedAgentsAgentToolset20260401Params;
use Anthropic\Beta\Agents\BetaManagedAgentsMCPToolsetParams;
use Anthropic\Beta\Agents\BetaManagedAgentsURLMCPServerParams;
use Anthropic\Beta\Sessions\BetaManagedAgentsAgentParams;

// Agent declares MCP server (no auth here -- auth goes in a vault)
$agent = $client->beta->agents->create(
    name: 'GitHub Assistant',
    model: 'claude-opus-5',
    mcpServers: [
        BetaManagedAgentsURLMCPServerParams::with(
            type: 'url',
            name: 'github',
            url: 'https://api.githubcopilot.com/mcp/',
        ),
    ],
    tools: [
        BetaManagedAgentsAgentToolset20260401Params::with(type: 'agent_toolset_20260401'),
        BetaManagedAgentsMCPToolsetParams::with(
            type: 'mcp_toolset',
```

```
            mcpServerName: 'github',
        ),
    ],
);

// Session attaches vault(s) containing credentials for those MCP server URLs
$session = $client->beta->sessions->create(
    agent: BetaManagedAgentsAgentParams::with(
        type: 'agent',
        id: $agent->id,
        version: $agent->version,
    ),
    environmentID: $environment->id,
    vaultIDs: [$vault->id],
);
```

See `shared/managed-agents-tools.md` ?Vaults for creating vaults and adding credentials.

Vaults

```php
// Create a vault
$vault = $client->beta->vaults->create(
    displayName: 'Alice',
    metadata: ['external_user_id' => 'usr_abc123'],
);
echo $vault->id . "\n"; // "vlt_01ABC..."

// Add an OAuth credential
$credential = $client->beta->vaults->credentials->create(
    vaultID: $vault->id,
    displayName: "Alice's Slack",
    auth: [
        'type' => 'mcp_oauth',
        'mcp_server_url' => 'https://mcp.slack.com/mcp',
        'access_token' => 'xoxp-...',
        'expires_at' => '2026-04-15T00:00:00Z',
        'refresh' => [
            'token_endpoint' => 'https://slack.com/api/oauth.v2.access',
            'client_id' => '1234567890.0987654321',
            'scope' => 'channels:read chat:write',
            'refresh_token' => 'xoxe-1-...',
            'token_endpoint_auth' => [
                'type' => 'client_secret_post',
                'client_secret' => 'abc123...',
            ],
        ],
    ],
);

// Rotate the credential (e.g., after a token refresh)
$client->beta->vaults->credentials->update(
    $credential->id,
    vaultID: $vault->id,
    auth: [
        'type' => 'mcp_oauth',
        'access_token' => 'xoxp-new-...',
        'expires_at' => '2026-05-15T00:00:00Z',
        'refresh' => ['refresh_token' => 'xoxe-1-new-...'],
    ],
);

// Archive a vault
$client->beta->vaults->archive($vault->id);
```

```
## GitHub Repository Integration

Mount a GitHub repository as a session resource (a vault holds the GitHub MCP credential):

```php
$session = $client->beta->sessions->create(
    agent: $agent->id,
    environmentID: $environment->id,
    vaultIDs: [$vault->id],
    resources: [
        [
            'type' => 'github_repository',
            'url' => 'https://github.com/org/repo',
            'mount_path' => '/workspace/repo',
            'authorization_token' => 'ghp_your_github_token',
        ],
    ],
);
```

Multiple repositories on the same session:

```php
$resources = [
    [
        'type' => 'github_repository',
        'url' => 'https://github.com/org/frontend',
        'mount_path' => '/workspace/frontend',
        'authorization_token' => 'ghp_your_github_token',
    ],
    [
        'type' => 'github_repository',
        'url' => 'https://github.com/org/backend',
        'mount_path' => '/workspace/backend',
        'authorization_token' => 'ghp_your_github_token',
    ],
];
```

Rotating a repository's authorization token:

```php
$listed = $client->beta->sessions->resources->list($session->id);
$repoResourceId = $listed->data[0]->id;

$client->beta->sessions->resources->update(
    $repoResourceId,
    sessionID: $session->id,
    authorizationToken: 'ghp_your_new_github_token',
);
```
</doc>

<doc path="python/claude-api/README.md">
Claude API -- Python

Installation

```bash
pip install anthropic
```

Client Initialization

```python
import anthropic

# Default -- resolves credentials from the environment:
# ANTHROPIC_API_KEY, or ANTHROPIC_AUTH_TOKEN, or an `ant auth login` profile.
```
```

```
# Prefer this for local dev; don't hardcode a key.
client = anthropic.Anthropic()

# Explicit API key (only when you must inject a specific key)
client = anthropic.Anthropic(api_key="your-api-key")

# Async client
async_client = anthropic.AsyncAnthropic()
```

Client Configuration

Per-request overrides

Use `with_options()` to override client settings for a single call without mutating the client:

```python
client.with_options(timeout=5.0, max_retries=5).messages.create(
    model="claude-opus-5",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Hello"}],
)
```

Timeouts

Default request timeout is 10 minutes. Pass a float (seconds) or an `httpx.Timeout` for granular control. On timeout the SDK raises `anthropic.APITimeoutError` (and retries per `max_retries`).

```python
import httpx

client = anthropic.Anthropic(timeout=20.0)
client = anthropic.Anthropic(
    timeout=httpx.Timeout(60.0, read=5.0, write=10.0, connect=2.0),
)
```

Retries

The SDK auto-retries connection errors, 408, 409, 429, and >=500 with exponential backoff (default 2 retries). Set `max_retries` on the client or via `with_options()`; `max_retries=0` disables.

Async performance (aiohttp backend)

For high-concurrency async workloads, install `anthropic[aiohttp]` and pass `DefaultAioHttpClient` instead of the default httpx backend:

```python
from anthropic import AsyncAnthropic, DefaultAioHttpClient

async with AsyncAnthropic(http_client=DefaultAioHttpClient()) as client:
    ...
```

Custom HTTP client (proxy, base URL)

Use `DefaultHttpxClient` / `DefaultAsyncHttpxClient` -- not raw `httpx.Client` -- so the SDK's default timeouts and connection limits are preserved:

```python
from anthropic import Anthropic, DefaultHttpxClient

client = Anthropic(
    base_url="http://my.test.server.example.com:8083",  # or ANTHROPIC_BASE_URL env var
    http_client=DefaultHttpxClient(proxy="http://my.test.proxy.example.com"),
)
```

````
### Logging

Set `ANTHROPIC_LOG=debug` (or `info`) to enable SDK logging via the standard `logging` module.

---

## Basic Message Request

```python
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    messages=[
        {"role": "user", "content": "What is the capital of France?"}
    ]
)
# response.content is a list of content block objects (TextBlock, ThinkingBlock,
# ToolUseBlock, ...). Check .type before accessing .text.
for block in response.content:
    if block.type == "text":
        print(block.text)
```

---

## System Prompts

```python
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    system="You are a helpful coding assistant. Always provide examples in Python.",
    messages=[{"role": "user", "content": "How do I read a JSON file?"}]
)
```

### Mid-conversation system messages (model-gated)

For operator instructions that arrive mid-conversation (mode switches, injected state), append `{"role":
"system", ...}` to `messages` instead of editing top-level `system` -- this preserves the cached prefix and
carries operator authority. Must follow a user message (or an `assistant` message ending in server-tool use),
and must be either the last entry in `messages` or be followed by an `assistant` turn; cannot be
`messages[0]`. Unsupported models return a 400 (`role 'system' is not supported on this model`). See
`shared/prompt-caching.md` for when to use this vs. top-level `system`.

```python
response = client.messages.create(
    model=MODEL_ID,  # must support mid-conversation system messages
    max_tokens=16000,
    system=[{"type": "text", "text": STABLE_SYSTEM, "cache_control": {"type": "ephemeral"}}],
    messages=history + [
        {"role": "user", "content": user_message},
        {"role": "system", "content": "Terse mode enabled -- keep responses under 40 words."},
    ],
)  # No beta header needed -- use regular client.messages.create
```

---

## Vision (Images)

### Base64

```python
import base64

with open("image.png", "rb") as f:
    image_data = base64.standard_b64encode(f.read()).decode("utf-8")
````
````

```
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    messages=[{
        "role": "user",
        "content": [
            {
                "type": "image",
                "source": {
                    "type": "base64",
                    "media_type": "image/png",
                    "data": image_data
                }
            },
            {"type": "text", "text": "What's in this image?"}
        ]
    }]
)
```

URL

```python
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    messages=[{
        "role": "user",
        "content": [
            {
                "type": "image",
                "source": {
                    "type": "url",
                    "url": "https://example.com/image.png"
                }
            },
            {"type": "text", "text": "Describe this image"}
        ]
    }]
)
```

Prompt Caching

Cache large context to reduce costs (up to 90% savings). **Caching is a prefix match** -- any byte change anywhere in the prefix invalidates everything after it. For placement patterns, architectural guidance (frozen system prompt, deterministic tool order, where to put volatile content), and the silent-invalidator audit checklist, read `shared/prompt-caching.md`.

Automatic Caching (Recommended)

Use top-level `cache_control` to automatically cache the last cacheable block in the request -- no need to annotate individual content blocks:

```python
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    cache_control={"type": "ephemeral"},  # auto-caches the last cacheable block
    system="You are an expert on this large document...",
    messages=[{"role": "user", "content": "Summarize the key points"}]
)
```

Manual Cache Control

For fine-grained control, add `cache_control` to specific content blocks:

```python
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    system=[{
        "type": "text",
        "text": "You are an expert on this large document...",
        "cache_control": {"type": "ephemeral"}  # default TTL is 5 minutes
    }],
    messages=[{"role": "user", "content": "Summarize the key points"}]
)

# With explicit TTL (time-to-live)
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    system=[{
        "type": "text",
        "text": "You are an expert on this large document...",
        "cache_control": {"type": "ephemeral", "ttl": "1h"}  # 1 hour TTL
    }],
    messages=[{"role": "user", "content": "Summarize the key points"}]
)
```

Verifying Cache Hits

```python
print(response.usage.cache_creation_input_tokens)  # tokens written to cache (~1.25x cost)
print(response.usage.cache_read_input_tokens)      # tokens served from cache (~0.1x cost)
print(response.usage.input_tokens)                 # uncached tokens (full cost)
```

If `cache_read_input_tokens` is zero across repeated identical-prefix requests, a silent invalidator is at work -- `datetime.now()` or a UUID in the system prompt, unsorted `json.dumps()`, or a varying tool set. See `shared/prompt-caching.md` for the full audit table.

Extended Thinking

> **Fable 5, Claude Opus 5, Opus 4.8, Opus 4.7, Opus 4.6, and Sonnet 4.6:** Use adaptive thinking. `budget_tokens` is removed on Fable 5, Claude Opus 5, Opus 4.8, and 4.7 (400 if sent); deprecated on Opus 4.6 and Sonnet 4.6.
> **Claude Opus 5:** thinking is on by default -- omitting `thinking` runs adaptive (`{"type": "adaptive"}` is equivalent), unlike Opus 4.8/4.7 where omitting it meant no thinking. `{"type": "disabled"}` is accepted only at effort `high` or lower; pairing it with `xhigh`/`max` returns a 400.
> **Older models:** Use `thinking: {type: "enabled", budget_tokens: N}` (must be < `max_tokens`, min 1024).

```python
# Fable 5 / Claude Opus 5 / Opus 4.8 / 4.7 / 4.6: adaptive thinking (recommended)
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    thinking={"type": "adaptive", "display": "summarized"},  # display opt-in: default is omitted (empty thinking text) on Fable 5 / Mythos 5 / Claude Opus 5 / Opus 4.8 / 4.7
    output_config={"effort": "high"},  # low | medium | high | xhigh | max
    messages=[{"role": "user", "content": "Solve this step by step..."}]
)

# Access thinking and response
for block in response.content:
    if block.type == "thinking":
        print(f"Thinking: {block.thinking}")
    elif block.type == "text":
        print(f"Response: {block.text}")
```

```
## Error Handling

```python
import anthropic

try:
    response = client.messages.create(...)
except anthropic.BadRequestError as e:
    print(f"Bad request: {e.message}")
except anthropic.AuthenticationError:
    print("Invalid API key")
except anthropic.PermissionDeniedError:
    print("API key lacks required permissions")
except anthropic.NotFoundError:
    print("Invalid model or endpoint")
except anthropic.RateLimitError as e:
    retry_after = int(e.response.headers.get("retry-after", "60"))
    print(f"Rate limited. Retry after {retry_after}s.")
except anthropic.APIStatusError as e:
    if e.status_code >= 500:
        print(f"Server error ({e.status_code}). Retry later.")
    else:
        print(f"API error: {e.message}")
except anthropic.APIConnectionError:
    print("Network error. Check internet connection.")
```

Response Helpers

Every response object exposes `_request_id` (populated from the `request-id` header) -- log it when reporting
failures to Anthropic. Despite the underscore prefix, this property is public.

```python
message = client.messages.create(...)
print(message._request_id)       # req_018EeWyXxfu5pfWkrYcMdjWG
print(message.to_json())          # serialize the Pydantic model
print(message.to_dict())          # plain dict
```

To access raw headers or other response metadata, use `.with_raw_response`:

```python
raw = client.messages.with_raw_response.create(
    model="claude-opus-5",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Hello"}],
)
print(raw.headers.get("request-id"))
message = raw.parse()  # the Message object messages.create() would have returned
```

Multi-Turn Conversations

The API is stateless -- send the full conversation history each time.

```python
class ConversationManager:
    """Manage multi-turn conversations with the Claude API."""

    def __init__(self, client: anthropic.Anthropic, model: str, system: str = None):
        self.client = client
        self.model = model
        self.system = system
        self.messages = []

    def send(self, user_message: str, **kwargs) -> str:
```
```

```
        """Send a message and get a response."""
        self.messages.append({"role": "user", "content": user_message})

        response = self.client.messages.create(
            model=self.model,
            max_tokens=kwargs.get("max_tokens", 16000),
            system=self.system,
            messages=self.messages,
            **kwargs
        )

        assistant_message = next(
            (b.text for b in response.content if b.type == "text"), ""
        )
        self.messages.append({"role": "assistant", "content": assistant_message})

        return assistant_message

# Usage
conversation = ConversationManager(
    client=anthropic.Anthropic(),
    model="claude-opus-5",
    system="You are a helpful assistant."
)

response1 = conversation.send("My name is Alice.")
response2 = conversation.send("What's my name?")  # Claude remembers "Alice"
```

Rules:

- Consecutive same-role messages are allowed -- the API combines them into a single turn
- First message must be `user`
- `role: "system"` messages are allowed mid-conversation on supporting models (no beta header needed) -- see
? Mid-conversation system messages above

Compaction (long conversations)

> **Beta, Fable 5, Claude Opus 5, Opus 4.8, Opus 4.7, Opus 4.6, and Sonnet 4.6.** When conversations approach the 200K context window, compaction automatically summarizes earlier context server-side. The API returns a `compaction` block; you must pass it back on subsequent requests -- append `response.content`, not just the text.

```python
import anthropic

client = anthropic.Anthropic()
messages = []

def chat(user_message: str) -> str:
    messages.append({"role": "user", "content": user_message})

    response = client.beta.messages.create(
        betas=["compact-2026-01-12"],
        model="claude-opus-5",
        max_tokens=16000,
        messages=messages,
        context_management={
            "edits": [{"type": "compact_20260112"}]
        }
    )

    # Append full content -- compaction blocks must be preserved
    messages.append({"role": "assistant", "content": response.content})

    return next(block.text for block in response.content if block.type == "text")

# Compaction triggers automatically when context grows large
```

```
print(chat("Help me build a Python web scraper"))
print(chat("Add support for JavaScript-rendered pages"))
print(chat("Now add rate limiting and error handling"))
```

Stop Reasons

The `stop_reason` field in the response indicates why the model stopped generating:

Value	Meaning
`end_turn`	Claude finished its response naturally
`max_tokens`	Hit the `max_tokens` limit -- increase it or use streaming
`stop_sequence`	Hit a custom stop sequence
`tool_use`	Claude wants to call a tool -- execute it and continue
`pause_turn`	Model paused and can be resumed (agentic flows)
`refusal`	Claude refused for safety reasons -- check `stop_details`

Structured Stop Details

When `stop_reason` is `"refusal"`, the response includes a `stop_details` object with structured information about the refusal:

```python
if response.stop_reason == "refusal" and response.stop_details:
    print(f"Category: {response.stop_details.category}")   # e.g. "cyber", "bio", "reasoning_extraction",
"frontier_llm", or None -- see docs for the full set
    print(f"Explanation: {response.stop_details.explanation}")
```

Refusal Fallbacks (Claude Fable 5) -- opt in by default

Fallbacks are **opt-in**: without them a refused request simply stops. Include the server-side `fallbacks` parameter in `claude-fable-5` code by default -- on a policy decline the API re-runs the same request on the fallback model inside the same call. A decline before any output isn't billed (a mid-stream decline bills the streamed partial); the rescue bills at the fallback model's own rates, with cache repricing applied automatically.

```python
response = client.beta.messages.create(
    model="claude-fable-5",
    max_tokens=16000,
    betas=["server-side-fallback-2026-06-01"],
    fallbacks=[{"model": "claude-opus-4-8"}],
    messages=[{"role": "user", "content": "..."}],
)

# Switch points: one fallback block per model that ran and declined this turn
for block in response.content:
    if block.type == "fallback":
        print(f"{block.from_.model} declined; {block.to.model} continued")

# Served-by signal -- covers sticky turns, which carry no fallback block.
# Pair with stop_reason: the fallback model can itself refuse.
fallback_ran = any(
    entry.type == "fallback_message" for entry in response.usage.iterations or []
)
if fallback_ran and response.stop_reason != "refusal":
    print(f"Served by {response.model}")
```

A `stop_reason: "refusal"` on the final response means the whole chain refused. The header must be exactly `server-side-fallback-2026-06-01` **for this array form**; the newer `fallbacks: "default"` scalar form uses `server-side-fallback-2026-07-01` instead (see `shared/model-migration.md` -> Migrating to Claude Opus 5 -> New API features), and pairing either header with the other form returns a 400. The parameter is rejected on the Batches API and unavailable on Amazon Bedrock, Vertex AI, and Microsoft Foundry -- register the client-side `BetaRefusalFallbackMiddleware` on the client there instead. Full semantics (sticky routing, billing, streaming, echoing fallback turns back): `shared/model-migration.md` -> Migrating to Claude Fable 5

````
-> `refusal` stop reason.

---

## Cost Optimization Strategies

### 1. Use Prompt Caching for Repeated Context

```python
# Automatic caching (simplest -- caches the last cacheable block)
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    cache_control={"type": "ephemeral"},
    system=large_document_text,  # e.g., 50KB of context
    messages=[{"role": "user", "content": "Summarize the key points"}]
)

# First request: full cost
# Subsequent requests: ~90% cheaper for cached portion
```

### 2. Choose the Right Model

```python
# Default to Opus for most tasks
response = client.messages.create(
    model="claude-opus-5",  # $5.00/$25.00 per 1M tokens
    max_tokens=16000,
    messages=[{"role": "user", "content": "Explain quantum computing"}]
)

# Use Sonnet for high-volume production workloads
standard_response = client.messages.create(
    model="claude-sonnet-5",  # $3.00/$15.00 per 1M tokens
    max_tokens=16000,
    messages=[{"role": "user", "content": "Summarize this document"}]
)

# Use Haiku only for simple, speed-critical tasks
simple_response = client.messages.create(
    model="claude-haiku-4-5",  # $1.00/$5.00 per 1M tokens
    max_tokens=256,
    messages=[{"role": "user", "content": "Classify this as positive or negative"}]
)
```

### 3. Use Token Counting Before Requests

```python
count_response = client.messages.count_tokens(
    model="claude-opus-5",
    messages=messages,
    system=system
)

estimated_input_cost = count_response.input_tokens * 0.000005  # $5/1M tokens
print(f"Estimated input cost: ${estimated_input_cost:.4f}")
```

---

## Retry with Exponential Backoff

> **Note:** The Anthropic SDK automatically retries rate limit (429) and server errors (5xx) with exponential
backoff. You can configure this with `max_retries` (default: 2). Only implement custom retry logic if you
need behavior beyond what the SDK provides.

```python
import time
````
````

```
import random
import anthropic

def call_with_retry(
    client: anthropic.Anthropic,
    max_retries: int = 5,
    base_delay: float = 1.0,
    max_delay: float = 60.0,
    **kwargs
):
    """Call the API with exponential backoff retry."""
    last_exception = None

    for attempt in range(max_retries):
        try:
            return client.messages.create(**kwargs)
        except anthropic.RateLimitError as e:
            last_exception = e
        except anthropic.APIStatusError as e:
            if e.status_code >= 500:
                last_exception = e
            else:
                raise  # Client errors (4xx except 429) should not be retried

        delay = min(base_delay * (2 ** attempt) + random.uniform(0, 1), max_delay)
        print(f"Retry {attempt + 1}/{max_retries} after {delay:.1f}s")
        time.sleep(delay)

    raise last_exception
```
</doc>

<doc path="python/claude-api/batches.md">
Message Batches API -- Python

The Batches API (`POST /v1/messages/batches`) processes Messages API requests asynchronously at 50% of standard prices.

Key Facts

- Up to 100,000 requests or 256 MB per batch
- Most batches complete within 1 hour; maximum 24 hours
- Results available for 29 days after creation
- 50% cost reduction on all token usage
- All Messages API features supported (vision, tools, caching, etc.)

Create a Batch

```python
import anthropic
from anthropic.types.message_create_params import MessageCreateParamsNonStreaming
from anthropic.types.messages.batch_create_params import Request

client = anthropic.Anthropic()

message_batch = client.messages.batches.create(
    requests=[
        Request(
            custom_id="request-1",
            params=MessageCreateParamsNonStreaming(
                model="claude-opus-5",
                max_tokens=16000,
                messages=[{"role": "user", "content": "Summarize climate change impacts"}]
            )
        ),
        Request(
            custom_id="request-2",
            params=MessageCreateParamsNonStreaming(
```

```
                model="claude-opus-5",
                max_tokens=16000,
                messages=[{"role": "user", "content": "Explain quantum computing basics"}]
            )
        ),
    ]
)

print(f"Batch ID: {message_batch.id}")
print(f"Status: {message_batch.processing_status}")
```

Poll for Completion

```python
import time

while True:
    batch = client.messages.batches.retrieve(message_batch.id)
    if batch.processing_status == "ended":
        break
    print(f"Status: {batch.processing_status}, processing: {batch.request_counts.processing}")
    time.sleep(60)

print("Batch complete!")
print(f"Succeeded: {batch.request_counts.succeeded}")
print(f"Errored: {batch.request_counts.errored}")
```

Retrieve Results

> **Note:** Examples below use `match/case` syntax, requiring Python 3.10+. For earlier versions, use
`if/elif` chains instead.

```python
for result in client.messages.batches.results(message_batch.id):
    match result.result.type:
        case "succeeded":
            msg = result.result.message
            text = next((b.text for b in msg.content if b.type == "text"), "")
            print(f"[{result.custom_id}] {text[:100]}")
        case "errored":
            if result.result.error.type == "invalid_request":
                print(f"[{result.custom_id}] Validation error - fix request and retry")
            else:
                print(f"[{result.custom_id}] Server error - safe to retry")
        case "canceled":
            print(f"[{result.custom_id}] Canceled")
        case "expired":
            print(f"[{result.custom_id}] Expired - resubmit")
```

Cancel a Batch

```python
cancelled = client.messages.batches.cancel(message_batch.id)
print(f"Status: {cancelled.processing_status}")  # "canceling"
```

List Batches (auto-pagination)

Iterating the return value of any `list()` call auto-paginates across all pages -- do not index into `.data`

````
if you want the full set:

```python
for batch in client.messages.batches.list(limit=20):
    print(batch.id, batch.processing_status)
```

For manual control, use `first_page.has_next_page()` / `first_page.get_next_page()` /
`first_page.next_page_info()`; `first_page.data` holds the current page's items and `first_page.last_id` is
the cursor.

---

## Batch with Prompt Caching

```python
shared_system = [
    {"type": "text", "text": "You are a literary analyst."},
    {
        "type": "text",
        "text": large_document_text,  # Shared across all requests
        "cache_control": {"type": "ephemeral"}
    }
]

message_batch = client.messages.batches.create(
    requests=[
        Request(
            custom_id=f"analysis-{i}",
            params=MessageCreateParamsNonStreaming(
                model="claude-opus-5",
                max_tokens=16000,
                system=shared_system,
                messages=[{"role": "user", "content": question}]
            )
        )
        for i, question in enumerate(questions)
    ]
)
```

---

## Full End-to-End Example

```python
import anthropic
import time
from anthropic.types.message_create_params import MessageCreateParamsNonStreaming
from anthropic.types.messages.batch_create_params import Request

client = anthropic.Anthropic()

# 1. Prepare requests
items_to_classify = [
    "The product quality is excellent!",
    "Terrible customer service, never again.",
    "It's okay, nothing special.",
]

requests = [
    Request(
        custom_id=f"classify-{i}",
        params=MessageCreateParamsNonStreaming(
            model="claude-haiku-4-5",
            max_tokens=50,
            messages=[{
                "role": "user",
                "content": f"Classify as positive/negative/neutral (one word): {text}"
            }]
````
````

```
        )
    )
    for i, text in enumerate(items_to_classify)
]

# 2. Create batch
batch = client.messages.batches.create(requests=requests)
print(f"Created batch: {batch.id}")

# 3. Wait for completion
while True:
    batch = client.messages.batches.retrieve(batch.id)
    if batch.processing_status == "ended":
        break
    time.sleep(10)

# 4. Collect results
results = {}
for result in client.messages.batches.results(batch.id):
    if result.result.type == "succeeded":
        msg = result.result.message
        results[result.custom_id] = next((b.text for b in msg.content if b.type == "text"), "")

for custom_id, classification in sorted(results.items()):
    print(f"{custom_id}: {classification}")
```
</doc>

<doc path="python/claude-api/files-api.md">
Files API -- Python

The Files API uploads files for use in Messages API requests. Reference files via `file_id` in content blocks, avoiding re-uploads across multiple API calls.

Beta: Pass `betas=["files-api-2025-04-14"]` in your API calls (the SDK sets the required header automatically).

Key Facts

- Maximum file size: 500 MB
- Total storage: 100 GB per organization
- Files persist until deleted
- File operations (upload, list, delete) are free; content used in messages is billed as input tokens
- Not available on Amazon Bedrock or Google Vertex AI

Upload a File

The `file` argument accepts a `(filename, content, content_type)` tuple, a `pathlib.Path` (or any `PathLike` -- read for you, async-safe with `AsyncAnthropic`), or an open binary file object.

```python
import anthropic
from pathlib import Path

client = anthropic.Anthropic()

uploaded = client.beta.files.upload(
    file=("report.pdf", open("report.pdf", "rb"), "application/pdf"),
)
# or: client.beta.files.upload(file=Path("report.pdf"))
print(f"File ID: {uploaded.id}")
print(f"Size: {uploaded.size_bytes} bytes")
```

Use a File in Messages

PDF / Text Document

```python
response = client.beta.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    messages=[{
        "role": "user",
        "content": [
            {"type": "text", "text": "Summarize the key findings in this report."},
            {
                "type": "document",
                "source": {"type": "file", "file_id": uploaded.id},
                "title": "Q4 Report",           # optional
                "citations": {"enabled": True}   # optional, enables citations
            }
        ]
    }],
    betas=["files-api-2025-04-14"],
)
for block in response.content:
    if block.type == "text":
        print(block.text)
```

Image

```python
image_file = client.beta.files.upload(
    file=("photo.png", open("photo.png", "rb"), "image/png"),
)

response = client.beta.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    messages=[{
        "role": "user",
        "content": [
            {"type": "text", "text": "What's in this image?"},
            {
                "type": "image",
                "source": {"type": "file", "file_id": image_file.id}
            }
        ]
    }],
    betas=["files-api-2025-04-14"],
)
```

Manage Files

List Files

Iterate the list result directly -- the SDK auto-paginates across all pages. Only use `.data` if you want the first page only.

```python
for f in client.beta.files.list():
    print(f"{f.id}: {f.filename} ({f.size_bytes} bytes)")
```

Get File Metadata

```python
file_info = client.beta.files.retrieve_metadata("file_011CNha8iCJcU1wXNR6q4V8w")
print(f"Filename: {file_info.filename}")
print(f"MIME type: {file_info.mime_type}")
```

Delete a File

```python
client.beta.files.delete("file_011CNha8iCJcU1wXNR6q4V8w")
```

Download a File

Only files created by the code execution tool or skills can be downloaded (not user-uploaded files).

```python
file_content = client.beta.files.download("file_011CNha8iCJcU1wXNR6q4V8w")
file_content.write_to_file("output.txt")
```

Full End-to-End Example

Upload a document once, ask multiple questions about it:

```python
import anthropic

client = anthropic.Anthropic()

# 1. Upload once
uploaded = client.beta.files.upload(
    file=("contract.pdf", open("contract.pdf", "rb"), "application/pdf"),
)
print(f"Uploaded: {uploaded.id}")

# 2. Ask multiple questions using the same file_id
questions = [
    "What are the key terms and conditions?",
    "What is the termination clause?",
    "Summarize the payment schedule.",
]

for question in questions:
    response = client.beta.messages.create(
        model="claude-opus-5",
        max_tokens=16000,
        messages=[{
            "role": "user",
            "content": [
                {"type": "text", "text": question},
                {
                    "type": "document",
                    "source": {"type": "file", "file_id": uploaded.id}
                }
            ]
        }],
        betas=["files-api-2025-04-14"],
    )
    print(f"\nQ: {question}")
    text = next((b.text for b in response.content if b.type == "text"), "")
    print(f"A: {text[:200]}")

# 3. Clean up when done
client.beta.files.delete(uploaded.id)
```
</doc>

<doc path="python/claude-api/streaming.md">
Streaming -- Python

Quick Start

```python
with client.messages.stream(
    model="claude-opus-5",
    max_tokens=64000,
    messages=[{"role": "user", "content": "Write a story"}]
) as stream:
    for text in stream.text_stream:
        print(text, end="", flush=True)
```

Async

```python
async with async_client.messages.stream(
    model="claude-opus-5",
    max_tokens=64000,
    messages=[{"role": "user", "content": "Write a story"}]
) as stream:
    async for text in stream.text_stream:
        print(text, end="", flush=True)
```

Low-level: `stream=True`

`messages.stream()` (above) is the recommended helper -- it accumulates state and exposes `text_stream` / `get_final_message()`. If you only need the raw event iterator and want lower memory use, pass `stream=True` to `messages.create()` instead:

```python
for event in client.messages.create(
    model="claude-opus-5",
    max_tokens=64000,
    messages=[{"role": "user", "content": "Write a story"}],
    stream=True,
):
    print(event.type)
```

No final-message accumulation is done for you in this form.

Handling Different Content Types

Claude may return text, thinking blocks, or tool use. Handle each appropriately:

> **Fable 5 / Claude Opus 5 / Opus 4.8 / Opus 4.7 / Opus 4.6:** Use `thinking: {type: "adaptive"}`. On Claude Opus 5 adaptive is also what you get by omitting `thinking` entirely. On older models, use `thinking: {type: "enabled", budget_tokens: N}` instead.

```python
with client.messages.stream(
    model="claude-opus-5",
    max_tokens=64000,
    thinking={"type": "adaptive", "display": "summarized"},  # display opt-in: default is omitted (empty thinking text) on Fable 5 / Mythos 5 / Claude Opus 5 / Opus 4.8 / 4.7
    messages=[{"role": "user", "content": "Analyze this problem"}]
) as stream:
    for event in stream:
        if event.type == "content_block_start":
            if event.content_block.type == "thinking":
                print("\n[Thinking...]")
            elif event.content_block.type == "text":
                print("\n[Response:]")

        elif event.type == "content_block_delta":
            if event.delta.type == "thinking_delta":
                print(event.delta.thinking, end="", flush=True)
            elif event.delta.type == "text_delta":
                print(event.delta.text, end="", flush=True)
```

```

---

## Streaming with Tool Use

The Python tool runner supports streaming: pass `stream=True` to `client.beta.messages.tool_runner(...)` and
each iteration yields a stream you consume event-by-event, with `get_final_message()` for the accumulated
message per turn (see `shared/tool-use-concepts.md` -> Tool Runner vs Manual Loop). Use the manual-loop
pattern below only when you're not using the tool runner and need per-token streaming with tools:

```python
with client.messages.stream(
    model="claude-opus-5",
    max_tokens=64000,
    tools=tools,
    messages=messages
) as stream:
    for text in stream.text_stream:
        print(text, end="", flush=True)

    response = stream.get_final_message()
    # Continue with tool execution if response.stop_reason == "tool_use"
```

Getting the Final Message

```python
with client.messages.stream(
    model="claude-opus-5",
    max_tokens=64000,
    messages=[{"role": "user", "content": "Hello"}]
) as stream:
    for text in stream.text_stream:
        print(text, end="", flush=True)

    # Get full message after streaming
    final_message = stream.get_final_message()
    print(f"\n\nTokens used: {final_message.usage.output_tokens}")
```

Streaming with Progress Updates

```python
def stream_with_progress(client, **kwargs):
    """Stream a response with progress updates."""
    total_tokens = 0
    content_parts = []

    with client.messages.stream(**kwargs) as stream:
        for event in stream:
            if event.type == "content_block_delta":
                if event.delta.type == "text_delta":
                    text = event.delta.text
                    content_parts.append(text)
                    print(text, end="", flush=True)

            elif event.type == "message_delta":
                if event.usage and event.usage.output_tokens is not None:
                    total_tokens = event.usage.output_tokens

        final_message = stream.get_final_message()

    print(f"\n\n[Tokens used: {total_tokens}]")
    return "".join(content_parts)
```
```

````
---

## Error Handling in Streams

```python
try:
    with client.messages.stream(
        model="claude-opus-5",
        max_tokens=64000,
        messages=[{"role": "user", "content": "Write a story"}]
    ) as stream:
        for text in stream.text_stream:
            print(text, end="", flush=True)
except anthropic.APIConnectionError:
    print("\nConnection lost. Please retry.")
except anthropic.RateLimitError:
    print("\nRate limited. Please wait and retry.")
except anthropic.APIStatusError as e:
    print(f"\nAPI error: {e.status_code}")
```

---

## Stream Event Types

| Event Type            | Description                | When it fires                    |
| --------------------- | -------------------------- | -------------------------------- |
| `message_start`       | Contains message metadata  | Once at the beginning            |
| `content_block_start` | New content block beginning | When a text/tool_use block starts |
| `content_block_delta` | Incremental content update | For each token/chunk             |
| `content_block_stop`  | Content block complete     | When a block finishes            |
| `message_delta`       | Message-level updates      | Contains `stop_reason`, usage    |
| `message_stop`        | Message complete           | Once at the end                  |

## Best Practices

1. **Always flush output** -- Use `flush=True` to show tokens immediately
2. **Handle partial responses** -- If the stream is interrupted, you may have incomplete content
3. **Track token usage** -- The `message_delta` event contains usage information
4. **Use timeouts** -- Set appropriate timeouts for your application
5. **Default to streaming** -- Use `.get_final_message()` to get the complete response even when streaming, giving you timeout protection without needing to handle individual events
6. **Large `max_tokens` without streaming raises `ValueError`** -- The SDK refuses non-streaming requests it estimates will exceed ~10 minutes (idle connections drop). Pass `stream=True` / use `messages.stream()`, or explicitly override `timeout`, to suppress the guard.

# Tool Use -- Python

For conceptual overview (tool definitions, tool choice, tips), see
[shared/tool-use-concepts.md](../../shared/tool-use-concepts.md).

## Tool Runner (Recommended)

**Beta:** The tool runner is in beta in the Python SDK.

Use the `@beta_tool` decorator to define tools as typed functions, then pass them to
`client.beta.messages.tool_runner()`:

```python
import anthropic
from anthropic import beta_tool

client = anthropic.Anthropic()

@beta_tool
def get_weather(location: str, unit: str = "celsius") -> str:
    """Get current weather for a location.
````
````

```
    Args:
        location: City and state, e.g., San Francisco, CA.
        unit: Temperature unit, either "celsius" or "fahrenheit".
    """
    # Your implementation here
    return f"72degF and sunny in {location}"

# The tool runner handles the agentic loop automatically
runner = client.beta.messages.tool_runner(
    model="claude-opus-5",
    max_tokens=16000,
    tools=[get_weather],
    messages=[{"role": "user", "content": "What's the weather in Paris?"}],
)

# Each iteration yields a BetaMessage; iteration stops when Claude is done
for message in runner:
    print(message)
```

For async usage, use `@beta_async_tool` with `async def` functions.

Key benefits of the tool runner:

- No manual loop -- the SDK handles calling tools and feeding results back
- Type-safe tool inputs via decorators
- Tool schemas are generated automatically from function signatures
- Iteration stops automatically when Claude has no more tool calls

Server tools with the tool runner

The runner's `tools` list accepts raw server-tool definitions (`web_search_20260209`, `web_fetch_20260209`, code execution) alongside decorated tools -- pass the literal tool dict; server tools run on Anthropic's servers, so there is no function to implement.

Caution -- the runner does not auto-resume `pause_turn` (as of `anthropic` 0.116.0). A long-running server-tool turn can stop with `stop_reason: "pause_turn"`. The runner only continues after a client tool produces a result, so a paused turn ends the loop and is returned as the final message -- no error, no warning, just a silently truncated answer. Unlike the TypeScript runner, the Python runner cannot be resumed mid-loop: it exits unconditionally when no client tool ran, and `runner.append_messages(...)` does not prevent the exit. To handle `pause_turn`, mirror the conversation history as you iterate, then restart the runner with the paused turn appended:

```python
messages = [{"role": "user", "content": user_input}]

max_restarts = 5  # cap pause_turn restarts, mirroring max_continuations advice
restarts = 0
while True:
    runner = client.beta.messages.tool_runner(
        model="claude-opus-5",
        max_tokens=16000,
        tools=tools,  # may mix @beta_tool functions and server-tool definitions
        messages=messages,
    )
    last = None
    for message in runner:
        last = message
        # Mirror the history -- the runner keeps its own copy and does not expose it
        messages.append({"role": "assistant", "content": message.content})
        tool_response = runner.generate_tool_call_response()  # cached; tools still run once
        if tool_response is not None:
            messages.append(tool_response)
    if last is None or last.stop_reason != "pause_turn":
        break
    restarts += 1
    if restarts > max_restarts:
        raise RuntimeError("giving up: turn still paused after max_restarts")
    # Paused mid-turn: `messages` already ends with the paused assistant
```

```
    # turn, so the next runner resumes it
```

Alternatively, use the manual loop below, which handles `pause_turn` explicitly.

MCP Tool Conversion Helpers

Beta. Convert [MCP (Model Context Protocol)](https://modelcontextprotocol.io/) tools, prompts, and resources to Anthropic API types for use with the tool runner. Requires `pip install anthropic[mcp]` (Python 3.10+).

> **Note:** The Claude API also supports an `mcp_servers` parameter that lets Claude connect directly to remote MCP servers. Use these helpers instead when you need local MCP servers, prompts, resources, or more control over the MCP connection.

MCP Tools with Tool Runner

```python
from anthropic import AsyncAnthropic
from anthropic.lib.tools.mcp import async_mcp_tool
from mcp import ClientSession
from mcp.client.stdio import stdio_client, StdioServerParameters

client = AsyncAnthropic()

async with stdio_client(StdioServerParameters(command="mcp-server")) as (read, write):
    async with ClientSession(read, write) as mcp_client:
        await mcp_client.initialize()

        tools_result = await mcp_client.list_tools()
        # tool_runner is sync -- returns the runner, not a coroutine
        runner = client.beta.messages.tool_runner(
            model="claude-opus-5",
            max_tokens=16000,
            messages=[{"role": "user", "content": "Use the available tools"}],
            tools=[async_mcp_tool(t, mcp_client) for t in tools_result.tools],
        )
        async for message in runner:
            print(message)
```

For sync usage, use `mcp_tool` instead of `async_mcp_tool`.

MCP Prompts

```python
from anthropic.lib.tools.mcp import mcp_message

prompt = await mcp_client.get_prompt(name="my-prompt")
response = await client.beta.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    messages=[mcp_message(m) for m in prompt.messages],
)
```

MCP Resources as Content

```python
from anthropic.lib.tools.mcp import mcp_resource_to_content

resource = await mcp_client.read_resource(uri="file:///path/to/doc.txt")
response = await client.beta.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    messages=[{
        "role": "user",
        "content": [
```

```
            mcp_resource_to_content(resource),
            {"type": "text", "text": "Summarize this document"},
        ],
    }],
)
```

Upload MCP Resources as Files

```python
from anthropic.lib.tools.mcp import mcp_resource_to_file

resource = await mcp_client.read_resource(uri="file:///path/to/data.json")
uploaded = await client.beta.files.upload(file=mcp_resource_to_file(resource))
```

Conversion functions raise `UnsupportedMCPValueError` if an MCP value cannot be converted (e.g., unsupported content types like audio, unsupported MIME types).

Manual Agentic Loop

Prefer the tool runner above. Drop to a manual loop only when you need control the runner does not expose (e.g., a custom transport, request shapes the SDK cannot build, or avoiding a beta dependency -- the runner is beta). Human-in-the-loop approval does *not* require a manual loop -- gate inside the tool function (return a "user declined" result) or inspect pending `tool_use` blocks in the `for message in runner:` body and call `runner.set_messages_params()`.

If you do need a manual loop:

```python
import anthropic

client = anthropic.Anthropic()
tools = [...]  # Your tool definitions
messages = [{"role": "user", "content": user_input}]

# Agentic loop: keep going until Claude stops calling tools
while True:
    response = client.messages.create(
        model="claude-opus-5",
        max_tokens=16000,
        tools=tools,
        messages=messages
    )

    # If Claude is done (no more tool calls), break
    if response.stop_reason == "end_turn":
        break

    # Server-side tool hit iteration limit; re-send to continue
    if response.stop_reason == "pause_turn":
        messages = [
            {"role": "user", "content": user_input},
            {"role": "assistant", "content": response.content},
        ]
        continue

    # Extract tool use blocks from the response
    tool_use_blocks = [b for b in response.content if b.type == "tool_use"]

    # Append assistant's response (including tool_use blocks)
    messages.append({"role": "assistant", "content": response.content})

    # Execute each tool and collect results
    tool_results = []
    for tool in tool_use_blocks:
        result = execute_tool(tool.name, tool.input)  # Your implementation
        tool_results.append({
```

```
            "type": "tool_result",
            "tool_use_id": tool.id,  # Must match the tool_use block's id
            "content": result
        })

    # Append tool results as a user message
    messages.append({"role": "user", "content": tool_results})

# Final response text
final_text = next(b.text for b in response.content if b.type == "text")
```

Handling Tool Results

```python
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    tools=tools,
    messages=[{"role": "user", "content": "What's the weather in Paris?"}]
)

for block in response.content:
    if block.type == "tool_use":
        tool_name = block.name
        tool_input = block.input
        tool_use_id = block.id

        result = execute_tool(tool_name, tool_input)

        followup = client.messages.create(
            model="claude-opus-5",
            max_tokens=16000,
            tools=tools,
            messages=[
                {"role": "user", "content": "What's the weather in Paris?"},
                {"role": "assistant", "content": response.content},
                {
                    "role": "user",
                    "content": [{
                        "type": "tool_result",
                        "tool_use_id": tool_use_id,
                        "content": result
                    }]
                }
            ]
        )
```

Multiple Tool Calls

```python
tool_results = []

for block in response.content:
    if block.type == "tool_use":
        result = execute_tool(block.name, block.input)
        tool_results.append({
            "type": "tool_result",
            "tool_use_id": block.id,
            "content": result
        })

# Send all results back at once
if tool_results:
    followup = client.messages.create(
```

```
        model="claude-opus-5",
        max_tokens=16000,
        tools=tools,
        messages=[
            *previous_messages,
            {"role": "assistant", "content": response.content},
            {"role": "user", "content": tool_results}
        ]
    )
```

Error Handling in Tool Results

```python
tool_result = {
    "type": "tool_result",
    "tool_use_id": tool_use_id,
    "content": "Error: Location 'xyz' not found. Please provide a valid city name.",
    "is_error": True
}
```

Tool Choice

```python
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    tools=tools,
    tool_choice={"type": "tool", "name": "get_weather"},  # Force specific tool
    messages=[{"role": "user", "content": "What's the weather in Paris?"}]
)
```

Code Execution

Basic Usage

```python
import anthropic

client = anthropic.Anthropic()

response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    messages=[{
        "role": "user",
        "content": "Calculate the mean and standard deviation of [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]"
    }],
    tools=[{
        "type": "code_execution_20260120",
        "name": "code_execution"
    }]
)

for block in response.content:
    if block.type == "text":
        print(block.text)
    elif block.type == "bash_code_execution_tool_result":
        print(f"stdout: {block.content.stdout}")
```

Upload Files for Analysis

```python
# 1. Upload a file
uploaded = client.beta.files.upload(file=open("sales_data.csv", "rb"))

# 2. Pass to code execution via container_upload block
# Code execution is GA; Files API is still beta (pass via extra_headers)
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    extra_headers={"anthropic-beta": "files-api-2025-04-14"},
    messages=[{
        "role": "user",
        "content": [
            {"type": "text", "text": "Analyze this sales data. Show trends and create a visualization."},
            {"type": "container_upload", "file_id": uploaded.id}
        ]
    }],
    tools=[{"type": "code_execution_20260120", "name": "code_execution"}]
)
```

Retrieve Generated Files

```python
import os

OUTPUT_DIR = "./claude_outputs"
os.makedirs(OUTPUT_DIR, exist_ok=True)

for block in response.content:
    if block.type == "bash_code_execution_tool_result":
        result = block.content
        if result.type == "bash_code_execution_result" and result.content:
            for file_ref in result.content:
                if file_ref.type == "bash_code_execution_output":
                    metadata = client.beta.files.retrieve_metadata(file_ref.file_id)
                    file_content = client.beta.files.download(file_ref.file_id)
                    # Use basename to prevent path traversal; validate result
                    safe_name = os.path.basename(metadata.filename)
                    if not safe_name or safe_name in (".", ".."):
                        print(f"Skipping invalid filename: {metadata.filename}")
                        continue
                    output_path = os.path.join(OUTPUT_DIR, safe_name)
                    file_content.write_to_file(output_path)
                    print(f"Saved: {output_path}")
```

Container Reuse

```python
# First request: set up environment
response1 = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    messages=[{"role": "user", "content": "Install tabulate and create data.json with sample data"}],
    tools=[{"type": "code_execution_20260120", "name": "code_execution"}]
)

# Get container ID from response
container_id = response1.container.id

# Second request: reuse the same container
response2 = client.messages.create(
    container=container_id,
    model="claude-opus-5",
    max_tokens=16000,
    messages=[{"role": "user", "content": "Read data.json and display as a formatted table"}],
    tools=[{"type": "code_execution_20260120", "name": "code_execution"}]
)
```

```

### Response Structure

```python
for block in response.content:
    if block.type == "text":
        print(block.text)  # Claude's explanation
    elif block.type == "server_tool_use":
        print(f"Running: {block.name} - {block.input}")  # What Claude is doing
    elif block.type == "bash_code_execution_tool_result":
        result = block.content
        if result.type == "bash_code_execution_result":
            if result.return_code == 0:
                print(f"Output: {result.stdout}")
            else:
                print(f"Error: {result.stderr}")
        else:
            print(f"Tool error: {result.error_code}")
    elif block.type == "text_editor_code_execution_tool_result":
        print(f"File operation: {block.content}")
```

Memory Tool

Basic Usage

```python
import anthropic

client = anthropic.Anthropic()

response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    messages=[{"role": "user", "content": "Remember that my preferred language is Python."}],
    tools=[{"type": "memory_20250818", "name": "memory"}],
)
```

SDK Memory Helper

Subclass `BetaAbstractMemoryTool`:

```python
from anthropic.lib.tools import BetaAbstractMemoryTool

class MyMemoryTool(BetaAbstractMemoryTool):
    def view(self, command): ...
    def create(self, command): ...
    def str_replace(self, command): ...
    def insert(self, command): ...
    def delete(self, command): ...
    def rename(self, command): ...

memory = MyMemoryTool()

# Use with tool runner
runner = client.beta.messages.tool_runner(
    model="claude-opus-5",
    max_tokens=16000,
    tools=[memory],
    messages=[{"role": "user", "content": "Remember my preferences"}],
)

for message in runner:
    print(message)
```
```

````
For full implementation examples, use WebFetch:

- `https://github.com/anthropics/anthropic-sdk-python/blob/main/examples/memory/basic.py`

---

## Structured Outputs

### JSON Outputs (Pydantic -- Recommended)

```python
from pydantic import BaseModel
from typing import List
import anthropic

class ContactInfo(BaseModel):
    name: str
    email: str
    plan: str
    interests: List[str]
    demo_requested: bool

client = anthropic.Anthropic()

response = client.messages.parse(
    model="claude-opus-5",
    max_tokens=16000,
    messages=[{
        "role": "user",
        "content": "Extract: Jane Doe (jane@co.com) wants Enterprise, interested in API and SDKs, wants a
demo."
    }],
    output_format=ContactInfo,
)

# response.parsed_output is a validated ContactInfo instance
contact = response.parsed_output
print(contact.name)           # "Jane Doe"
print(contact.interests)      # ["API", "SDKs"]
```

### Raw Schema

```python
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    messages=[{
        "role": "user",
        "content": "Extract info: John Smith (john@example.com) wants the Enterprise plan."
    }],
    output_config={
        "format": {
            "type": "json_schema",
            "schema": {
                "type": "object",
                "properties": {
                    "name": {"type": "string"},
                    "email": {"type": "string"},
                    "plan": {"type": "string"},
                    "demo_requested": {"type": "boolean"}
                },
                "required": ["name", "email", "plan", "demo_requested"],
                "additionalProperties": False
            }
        }
    }
)
````
````

```
import json
# output_config.format guarantees the first block is text with valid JSON
text = next(b.text for b in response.content if b.type == "text")
data = json.loads(text)
```

Strict Tool Use

```python
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    messages=[{"role": "user", "content": "Book a flight to Tokyo for 2 passengers on March 15"}],
    tools=[{
        "name": "book_flight",
        "description": "Book a flight to a destination",
        "strict": True,
        "input_schema": {
            "type": "object",
            "properties": {
                "destination": {"type": "string"},
                "date": {"type": "string", "format": "date"},
                "passengers": {"type": "integer", "enum": [1, 2, 3, 4, 5, 6, 7, 8]}
            },
            "required": ["destination", "date", "passengers"],
            "additionalProperties": False
        }
    }]
)
```

Using Both Together

```python
response = client.messages.create(
    model="claude-opus-5",
    max_tokens=16000,
    messages=[{"role": "user", "content": "Plan a trip to Paris next month"}],
    output_config={
        "format": {
            "type": "json_schema",
            "schema": {
                "type": "object",
                "properties": {
                    "summary": {"type": "string"},
                    "next_steps": {"type": "array", "items": {"type": "string"}}
                },
                "required": ["summary", "next_steps"],
                "additionalProperties": False
            }
        }
    },
    tools=[{
        "name": "search_flights",
        "description": "Search for available flights",
        "strict": True,
        "input_schema": {
            "type": "object",
            "properties": {
                "destination": {"type": "string"},
                "date": {"type": "string", "format": "date"}
            },
            "required": ["destination", "date"],
            "additionalProperties": False
        }
    }]
)
```
</doc>

````
<doc path="python/managed-agents/README.md">
# Managed Agents -- Python

> **Bindings not shown here:** This README covers the most common managed-agents flows for Python. If you
need a class, method, namespace, field, or behavior that isn't shown, WebFetch the Python SDK repo **or the
relevant docs page** from `shared/live-sources.md` rather than guess. Do not extrapolate from cURL shapes or
another language's SDK.

> **Agents are persistent -- create once, reference by ID.** Store the agent ID returned by `agents.create`
and pass it to every subsequent `sessions.create`; do not call `agents.create` in the request path.
**Recommended:** define agents and environments as version-controlled YAML applied with the `ant` CLI -- see
`shared/anthropic-cli.md` (its live-docs URL is in `shared/live-sources.md`). The CLI owns the control plane
(create/update); your code owns the data plane (sessions with the stored ID). The examples below show in-code
creation for when you must provision programmatically; in production the create call belongs in setup, not in
the request path.

## Installation

```bash
pip install anthropic
```

## Client Initialization

```python
import anthropic

# Default -- resolves credentials from the environment:
# ANTHROPIC_API_KEY, or ANTHROPIC_AUTH_TOKEN, or an `ant auth login` profile.
# Prefer this for local dev; don't hardcode a key.
client = anthropic.Anthropic()

# Explicit API key (only when you must inject a specific key)
client = anthropic.Anthropic(api_key="your-api-key")
```

---

## Create an Environment

```python
environment = client.beta.environments.create(
    name="my-dev-env",
    config={
        "type": "cloud",
        "networking": {"type": "unrestricted"},
    },
)
print(environment.id)  # env_...
```

---

## Create an Agent (required first step)

> ?? **There is no inline agent config.** `model`/`system`/`tools` live on the agent object, not the session.
Always start with `agents.create()` -- the session only takes `agent={"type": "agent", "id": agent.id}`.

### Minimal

```python
# 1. Create the agent (reusable, versioned)
agent = client.beta.agents.create(
    name="Coding Assistant",
    model="claude-opus-5",
    tools=[{"type": "agent_toolset_20260401", "default_config": {"enabled": True}}],
)

# 2. Start a session
session = client.beta.sessions.create(
````
````

```
    agent={"type": "agent", "id": agent.id, "version": agent.version},
    environment_id=environment.id,
)
print(session.id, session.status)
print(f"Trace: https://platform.claude.com/workspaces/default/sessions/{session.id}")  # swap 'default' for
your workspace ID if the API key is not in the Default workspace
```

With system prompt and custom tools

```python
import os

agent = client.beta.agents.create(
    name="Code Reviewer",
    model="claude-opus-5",
    system="You are a senior code reviewer.",
    tools=[
        {"type": "agent_toolset_20260401"},
        {
            "type": "custom",
            "name": "run_tests",
            "description": "Run the test suite",
            "input_schema": {
                "type": "object",
                "properties": {
                    "test_path": {"type": "string", "description": "Path to test file"}
                },
                "required": ["test_path"],
            },
        },
    ],
)

session = client.beta.sessions.create(
    agent={"type": "agent", "id": agent.id, "version": agent.version},
    environment_id=environment.id,
    title="Code review session",
    resources=[
        {
            "type": "github_repository",
            "url": "https://github.com/owner/repo",
            "mount_path": "/workspace/repo",
            "authorization_token": os.environ["GITHUB_TOKEN"],
            "branch": "main",
        }
    ],
)
```

Send a User Message

```python
client.beta.sessions.events.send(
    session_id=session.id,
    events=[
        {
            "type": "user.message",
            "content": [{"type": "text", "text": "Review the auth module"}],
        }
    ],
)
```

> ? **Stream-first:** Open the stream *before* (or concurrently with) sending the message. The stream only
delivers events that occur after it opens -- stream-after-send means early events arrive buffered in one
batch. See [Steering Patterns](../../shared/managed-agents-events.md#steering-patterns).

````
---

## Stream Events (SSE)

```python
import json

# Stream-first: open stream, then send while stream is live
with client.beta.sessions.events.stream(
    session_id=session.id,
) as stream:
    client.beta.sessions.events.send(
        session_id=session.id,
        events=[{"type": "user.message", "content": [{"type": "text", "text": "..."}]}],
    )
    for event in stream:
        ...  # process events

# Standalone stream iteration:
with client.beta.sessions.events.stream(
    session_id=session.id,
) as stream:
    for event in stream:
        if event.type == "agent.message":
            for block in event.content:
                if block.type == "text":
                    print(block.text, end="", flush=True)
        elif event.type == "agent.custom_tool_use":
            # Custom tool invocation -- session is now idle
            print(f"\nCustom tool call: {event.name}")
            print(f"Input: {json.dumps(event.input)}")
            # Send result back (see below)
        elif event.type == "session.status_idle":
            print("\n--- Agent idle ---")
        elif event.type == "session.status_terminated":
            print("\n--- Session terminated ---")
            break
```

---

## Provide Custom Tool Result

```python
client.beta.sessions.events.send(
    session_id=session.id,
    events=[
        {
            "type": "user.custom_tool_result",
            "custom_tool_use_id": "sevt_abc123",
            "content": [{"type": "text", "text": "All 42 tests passed."}],
        }
    ],
)
```

---

## Poll Events

```python
events = client.beta.sessions.events.list(
    session_id=session.id,
)
for event in events.data:
    print(f"{event.type}: {event.id}")
```

> ?? **Prefer the SDK over raw `requests`/`httpx`.** If you hand-roll a poll loop, don't assume `timeout=(5,
60)` or `httpx.Timeout(120)` caps total call duration -- both are **per-chunk** read timeouts (reset on every
````

````
byte), so a trickling response can block forever. For a hard wall-clock deadline, track `time.monotonic()` at
the loop level and bail explicitly, or wrap with `asyncio.wait_for()`. See [Receiving
Events](../../shared/managed-agents-events.md#receiving-events).

---

## Full Streaming Loop with Custom Tools

```python
import json

def run_custom_tool(tool_name: str, tool_input: dict) -> str:
    """Execute a custom tool and return the result."""
    if tool_name == "run_tests":
        # Your tool implementation here
        return "All tests passed."
    return f"Unknown tool: {tool_name}"

def run_session(client, session_id: str):
    """Stream events and handle custom tool calls."""
    while True:
        with client.beta.sessions.events.stream(
            session_id=session_id,
        ) as stream:
            tool_calls = []
            for event in stream:
                if event.type == "agent.message":
                    for block in event.content:
                        if block.type == "text":
                            print(block.text, end="", flush=True)
                elif event.type == "agent.custom_tool_use":
                    tool_calls.append(event)
                elif event.type == "session.status_idle":
                    break
                elif event.type == "session.status_terminated":
                    return

        if not tool_calls:
            break

        # Process custom tool calls
        results = []
        for call in tool_calls:
            result = run_custom_tool(call.name, call.input)
            results.append({
                "type": "user.custom_tool_result",
                "custom_tool_use_id": call.id,
                "content": [{"type": "text", "text": result}],
            })

        client.beta.sessions.events.send(
            session_id=session_id,
            events=results,
        )
```

---

## Upload a File

```python
with open("data.csv", "rb") as f:
    file = client.beta.files.upload(
        file=f,
    )

# Use in a session
session = client.beta.sessions.create(
````
````

````
    agent={"type": "agent", "id": agent.id, "version": agent.version},
    environment_id=environment.id,
    resources=[{"type": "file", "file_id": file.id, "mount_path": "/workspace/data.csv"}],
)
```

---

## List and Download Session Files

List files the agent wrote to `/mnt/session/outputs/` during a session, then download them.

```python
# List files associated with a session
files = client.beta.files.list(
    scope_id=session.id,
    betas=["managed-agents-2026-04-01"],
)
for f in files.data:
    print(f.filename, f.size_bytes)
    # Download each file and save to disk
    file_content = client.beta.files.download(f.id)
    file_content.write_to_file(f.filename)
```

> ? There's a brief indexing lag (~1-3s) between `session.status_idle` and output files appearing in
`files.list`. Retry once or twice if the list is empty.

---

## Session Management

```python
# Get session details
session = client.beta.sessions.retrieve(session_id="sesn_011CZxAbc123Def456")
print(session.status, session.usage)

# List sessions
sessions = client.beta.sessions.list()

# Delete a session
client.beta.sessions.delete(session_id="sesn_011CZxAbc123Def456")

# Archive a session
client.beta.sessions.archive(session_id="sesn_011CZxAbc123Def456")
```

---

## MCP Server Integration

```python
# Agent declares MCP server (no auth here -- auth goes in a vault)
agent = client.beta.agents.create(
    name="MCP Agent",
    model="claude-opus-5",
    mcp_servers=[
        {"type": "url", "name": "my-tools", "url": "https://my-mcp-server.example.com/sse"},
    ],
    tools=[
        {"type": "agent_toolset_20260401", "default_config": {"enabled": True}},
        {"type": "mcp_toolset", "mcp_server_name": "my-tools"},
    ],
)

# Session attaches vault(s) containing credentials for those MCP server URLs
session = client.beta.sessions.create(
    agent=agent.id,
    environment_id=environment.id,
    vault_ids=[vault.id],
````

```
)
```

See `shared/managed-agents-tools.md` ?Vaults for creating vaults and adding credentials.
</doc>

<doc path="ruby/claude-api/README.md">
Claude API -- Ruby

> **Note:** The Ruby SDK supports the Claude API. A tool runner is available in beta via
`client.beta.messages.tool_runner()`. Agent SDK is not yet available for Ruby.

Installation

```bash
gem install anthropic
```

Client Initialization

```ruby
require "anthropic"

# Default (uses ANTHROPIC_API_KEY env var)
client = Anthropic::Client.new

# Explicit API key
client = Anthropic::Client.new(api_key: "your-api-key")
```

Basic Message Request

```ruby
message = client.messages.create(
  model: :"claude-opus-5",
  max_tokens: 16000,
  messages: [
    { role: "user", content: "What is the capital of France?" }
  ]
)
# content is an array of polymorphic block objects (TextBlock, ThinkingBlock,
# ToolUseBlock, ...). .type is a Symbol -- compare with :text, not "text".
# .text raises NoMethodError on non-TextBlock entries.
message.content.each do |block|
  puts block.text if block.type == :text
end
```

Extended Thinking

> **Fable 5, Claude Opus 5, Opus 4.8, Opus 4.7, Opus 4.6, and Sonnet 4.6:** Use adaptive thinking.
`budget_tokens` is removed on Fable 5, Claude Opus 5, Opus 4.8, and 4.7 (400 if sent); deprecated on Opus 4.6
and Sonnet 4.6.
> **Claude Opus 5:** thinking is on by default -- omitting `thinking:` runs adaptive (`{ type: "adaptive" }`
is equivalent), unlike Opus 4.8/4.7 where omitting it meant no thinking. `{ type: "disabled" }` is accepted
only at effort `high` or lower; pairing it with `xhigh`/`max` returns a 400.
> **Older models:** Use `thinking: { type: "enabled", budget_tokens: N }` (must be < `max_tokens`, min 1024).

```ruby
message = client.messages.create(
  model: :"claude-opus-5",
  max_tokens: 16000,
  thinking: { type: "adaptive" },
  messages: [{ role: "user", content: "Solve: 27 * 453" }]
)
```

```
message.content.each do |block|
  case block.type
  when :thinking then puts "Thinking: #{block.thinking}"
  when :text then puts "Response: #{block.text}"
  end
end
```

Prompt Caching

`system_:` (trailing underscore -- avoids shadowing `Kernel#system`) takes an array of text blocks; set `cache_control` on the last block. Plain hashes work via the `OrHash` type alias. For placement patterns and the silent-invalidator audit checklist, see `shared/prompt-caching.md`.

```ruby
message = client.messages.create(
  model: :"claude-opus-5",
  max_tokens: 16000,
  system_: [
    { type: "text", text: long_system_prompt, cache_control: { type: "ephemeral" } }
  ],
  messages: [{ role: "user", content: "Summarize the key points" }]
)
```

For 1-hour TTL: `cache_control: { type: "ephemeral", ttl: "1h" }`. There's also a top-level `cache_control:` on `messages.create` that auto-places on the last cacheable block.

Verify hits via `message.usage.cache_creation_input_tokens` / `message.usage.cache_read_input_tokens`.

Stop Details

When `stop_reason` is `:refusal`, the response includes structured `stop_details`:

```ruby
if message.stop_reason == :refusal && message.stop_details
  puts "Category: #{message.stop_details.category}"     # e.g. :cyber, :bio, :reasoning_extraction,
:frontier_llm, or nil -- see docs for the full set
  puts "Explanation: #{message.stop_details.explanation}"
end
```

Refusal fallbacks (Claude Fable 5) -- opt in by default. Fallbacks are opt-in: without them a refused request simply stops. New `claude-fable-5` code should include the server-side `fallbacks` parameter (beta header `server-side-fallback-2026-06-01`, `fallbacks: [{model: "claude-opus-4-8"}]` on the beta messages call) by default. The exact Ruby binding (and the client-side middleware for providers without server-side support) is not documented here -- WebFetch the Ruby SDK repo's `examples/` from `shared/live-sources.md`; full semantics in `shared/model-migration.md` -> Migrating to Claude Fable 5 -> `refusal` stop reason.

Beta Features

`betas:` is only valid on `client.beta.messages.create`, not the non-beta path.

Task budgets

```ruby
response = client.beta.messages.create(
  model: :"claude-opus-5",
  max_tokens: 16000,
  output_config: { task_budget: { type: :tokens, total: 64_000 } },
  tools: [...],
  messages: [...],
  betas: ["task-budgets-2026-03-13"]
)
```

```

---

## Error Type

`APIStatusError` exposes a `.type` field for programmatic error classification:

```ruby
begin
  client.messages.create(...)
rescue Anthropic::Errors::APIStatusError => e
  puts e.type  # :rate_limit_error, :overloaded_error, etc.
end
```
</doc>

<doc path="ruby/claude-api/streaming.md">
Streaming -- Ruby

Streaming

```ruby
stream = client.messages.stream(
  model: :"claude-opus-5",
  max_tokens: 64000,
  messages: [{ role: "user", content: "Write a haiku" }]
)

stream.text.each { |text| print(text) }
```

</doc>

<doc path="ruby/claude-api/tool-use.md">
Tool Use -- Ruby

For conceptual overview (tool definitions, tool choice, tips), see
[shared/tool-use-concepts.md](../../shared/tool-use-concepts.md).

Tool Use

The Ruby SDK supports tool use via raw JSON schema definitions and also provides a beta tool runner for
automatic tool execution.

Tool Runner (Beta)

```ruby
class GetWeatherInput < Anthropic::BaseModel
  required :location, String, doc: "City and state, e.g. San Francisco, CA"
end

class GetWeather < Anthropic::BaseTool
  doc "Get the current weather for a location"

  input_schema GetWeatherInput

  def call(input)
    "The weather in #{input.location} is sunny and 72degF."
  end
end

client.beta.messages.tool_runner(
  model: :"claude-opus-5",
  max_tokens: 16000,
  tools: [GetWeather.new],
  messages: [{ role: "user", content: "What's the weather in San Francisco?" }]
).each_message do |message|
  puts message.content
```
```

```
end
```

Manual Loop

See the [shared tool use concepts](../../shared/tool-use-concepts.md) for the tool definition format and agentic loop pattern.

</doc>

<doc path="ruby/managed-agents/README.md">
Managed Agents -- Ruby

> **Bindings not shown here:** This README covers the most common managed-agents flows for Ruby. If you need a class, method, namespace, field, or behavior that isn't shown, WebFetch the Ruby SDK repo **or the relevant docs page** from `shared/live-sources.md` rather than guess. Do not extrapolate from cURL shapes or another language's SDK.

> **Agents are persistent -- create once, reference by ID.** Store the agent ID returned by `client.beta.agents.create` and pass it to every subsequent `client.beta.sessions.create`; do not call `agents.create` in the request path. **Recommended:** define agents and environments as version-controlled YAML applied with the `ant` CLI -- see `shared/anthropic-cli.md` (its live-docs URL is in `shared/live-sources.md`). The CLI owns the control plane (create/update); your code owns the data plane (sessions with the stored ID). The examples below show in-code creation for when you must provision programmatically; in production the create call belongs in setup, not in the request path.

Installation

```bash
gem install anthropic
```

Client Initialization

```ruby
require "anthropic"

# Default (uses ANTHROPIC_API_KEY env var)
client = Anthropic::Client.new

# Explicit API key
client = Anthropic::Client.new(api_key: "your-api-key")
```

> ?? **Trailing underscores:** The Ruby SDK uses `system_:` and `send_(` (trailing underscore) to avoid shadowing `Kernel#system` and `Kernel#send`. Use these forms throughout managed-agents code.

Create an Environment

```ruby
environment = client.beta.environments.create(
  name: "my-dev-env",
  config: {
    type: "cloud",
    networking: {type: "unrestricted"}
  }
)
puts "Environment ID: #{environment.id}" # env_...
```

Create an Agent (required first step)

> ?? **There is no inline agent config.** `model`/`system_`/`tools` live on the agent object, not the session. Always start with `client.beta.agents.create()` -- the session takes either `agent: agent.id` or the typed hash form `agent: {type: "agent", id: agent.id, version: agent.version}`.

```
### Minimal

```ruby
# 1. Create the agent (reusable, versioned)
agent = client.beta.agents.create(
  name: "Coding Assistant",
  model: :"claude-opus-5",
  system_: "You are a helpful coding assistant.",
  tools: [{type: "agent_toolset_20260401"}]
)

# 2. Start a session
session = client.beta.sessions.create(
  agent: {type: "agent", id: agent.id, version: agent.version},
  environment_id: environment.id,
  title: "Quickstart session"
)
puts "Session ID: #{session.id}"
puts "Trace: https://platform.claude.com/workspaces/default/sessions/#{session.id}"  # swap 'default' for
your workspace ID if the API key is not in the Default workspace
```

Updating an Agent

Updates create new versions; the agent object is immutable per version.

```ruby
updated_agent = client.beta.agents.update(
  agent.id,
  version: agent.version,
  system_: "You are a helpful coding agent. Always write tests."
)
puts "New version: #{updated_agent.version}"

# List all versions
client.beta.agents.versions.list(agent.id).auto_paging_each do |version|
  puts "Version #{version.version}: #{version.updated_at.iso8601}"
end

# Archive the agent
archived = client.beta.agents.archive(agent.id)
puts "Archived at: #{archived.archived_at.iso8601}"
```

Send a User Message

```ruby
client.beta.sessions.events.send_(
  session.id,
  events: [{
    type: "user.message",
    content: [{type: "text", text: "Review the auth module"}]
  }]
)
```

> ? **Stream-first:** Open the stream *before* (or concurrently with) sending the message. The stream only
delivers events that occur after it opens -- stream-after-send means early events arrive buffered in one
batch. See [Steering Patterns](../../shared/managed-agents-events.md#steering-patterns).

Stream Events (SSE)

```ruby
# Open the stream first, then send the user message
stream = client.beta.sessions.events.stream_events(session.id)
```
```

```
client.beta.sessions.events.send_(
  session.id,
  events: [{
    type: "user.message",
    content: [{type: "text", text: "Summarize the repo README"}]
  }]
)

stream.each do |event|
  case event.type
  in :"agent.message"
    event.content.each { |block| print block.text }
  in :"agent.tool_use"
    puts "\n[Using tool: #{event.name}]"
  in :"session.status_idle"
    break
  in :"session.error"
    puts "\n[Error: #{event.error&.message || "unknown"}]"
    break
  else
    # ignore other event types
  end
end
```

> ?? Event `.type` is a Symbol (compare with `:"agent.message"`, not `"agent.message"`).

Reconnecting and Tailing

When reconnecting mid-session, list past events first to dedupe, then tail live events:

```ruby
require "set"

stream = client.beta.sessions.events.stream_events(session.id)

# Stream is open and buffering. List history before tailing live.
seen_event_ids = Set.new
client.beta.sessions.events.list(session.id).auto_paging_each { |past| seen_event_ids << past.id }

# Tail live events, skipping anything already seen
stream.each do |event|
  next if seen_event_ids.include?(event.id)
  seen_event_ids << event.id
  case event.type
  in :"agent.message"
    event.content.each { |block| print block.text }
  in :"session.status_idle"
    break
  else
    # ignore other event types
  end
end
```

Provide Custom Tool Result

> ?? The Ruby managed-agents bindings for `user.custom_tool_result` are not yet documented in this skill or in the apps source examples. Refer to `shared/managed-agents-events.md` for the wire format and the `anthropic` Ruby gem repository for the corresponding params.

Poll Events

```ruby
client.beta.sessions.events.list(session.id).auto_paging_each do |event|
```

```
  puts "#{event.type}: #{event.id}"
end
```

Upload a File

```ruby
require "pathname"

file = client.beta.files.upload(file: Pathname("data.csv"))
puts "File ID: #{file.id}"

# Mount in a session
session = client.beta.sessions.create(
  agent: agent.id,
  environment_id: environment.id,
  resources: [
    {
      type: "file",
      file_id: file.id,
      mount_path: "/workspace/data.csv"
    }
  ]
)
```

Add and Manage Resources on an Existing Session

```ruby
# Attach an additional file to an open session
resource = client.beta.sessions.resources.add(
  session.id,
  type: "file",
  file_id: file.id
)
puts resource.id # "sesrsc_01ABC..."

# List resources on the session
listed = client.beta.sessions.resources.list(session.id)
listed.data.each { |entry| puts "#{entry.id} #{entry.type}" }

# Detach a resource
client.beta.sessions.resources.delete(resource.id, session_id: session.id)
```

List and Download Session Files

```ruby
files = client.beta.files.list(scope_id: "sesn_abc123", betas: ["managed-agents-2026-04-01"])
content = client.beta.files.download(files.data[0].id)
File.binwrite("output.txt", content.read)
```

Session Management

```ruby
# List environments
environments = client.beta.environments.list

# Retrieve a specific environment
env = client.beta.environments.retrieve(environment.id)

# Archive an environment (read-only, existing sessions continue)
client.beta.environments.archive(environment.id)
```

```
# Delete an environment (only if no sessions reference it)
client.beta.environments.delete(environment.id)

# Delete a session
client.beta.sessions.delete(session.id)
```

MCP Server Integration

```ruby
# Agent declares MCP server (no auth here -- auth goes in a vault)
agent = client.beta.agents.create(
  name: "GitHub Assistant",
  model: :"claude-opus-5",
  mcp_servers: [
    {
      type: "url",
      name: "github",
      url: "https://api.githubcopilot.com/mcp/"
    }
  ],
  tools: [
    {type: "agent_toolset_20260401"},
    {type: "mcp_toolset", mcp_server_name: "github"}
  ]
)

# Session attaches vault(s) containing credentials for those MCP server URLs
session = client.beta.sessions.create(
  agent: {type: "agent", id: agent.id, version: agent.version},
  environment_id: environment.id,
  vault_ids: [vault.id]
)
```

See `shared/managed-agents-tools.md` ?Vaults for creating vaults and adding credentials.

Vaults

```ruby
# Create a vault
vault = client.beta.vaults.create(
  display_name: "Alice",
  metadata: {external_user_id: "usr_abc123"}
)
puts vault.id # "vlt_01ABC..."

# Add an OAuth credential
credential = client.beta.vaults.credentials.create(
  vault.id,
  display_name: "Alice's Slack",
  auth: {
    type: "mcp_oauth",
    mcp_server_url: "https://mcp.slack.com/mcp",
    access_token: "xoxp-...",
    expires_at: "2026-04-15T00:00:00Z",
    refresh: {
      token_endpoint: "https://slack.com/api/oauth.v2.access",
      client_id: "1234567890.0987654321",
      scope: "channels:read chat:write",
      refresh_token: "xoxe-1-...",
      token_endpoint_auth: {
        type: "client_secret_post",
        client_secret: "abc123..."
      }
```

```
    }
  }
)

# Rotate the credential (e.g., after a token refresh)
client.beta.vaults.credentials.update(
  credential.id,
  vault_id: vault.id,
  auth: {
    type: "mcp_oauth",
    access_token: "xoxp-new-...",
    expires_at: "2026-05-15T00:00:00Z",
    refresh: {refresh_token: "xoxe-1-new-..."}
  }
)

# Archive a vault
client.beta.vaults.archive(vault.id)
```

GitHub Repository Integration

Mount a GitHub repository as a session resource (a vault holds the GitHub MCP credential):

```ruby
session = client.beta.sessions.create(
  agent: agent.id,
  environment_id: environment.id,
  vault_ids: [vault.id],
  resources: [
    {
      type: "github_repository",
      url: "https://github.com/org/repo",
      mount_path: "/workspace/repo",
      authorization_token: "ghp_your_github_token"
    }
  ]
)
```

Multiple repositories on the same session:

```ruby
resources = [
  {
    type: "github_repository",
    url: "https://github.com/org/frontend",
    mount_path: "/workspace/frontend",
    authorization_token: "ghp_your_github_token"
  },
  {
    type: "github_repository",
    url: "https://github.com/org/backend",
    mount_path: "/workspace/backend",
    authorization_token: "ghp_your_github_token"
  }
]
```

Rotating a repository's authorization token:

```ruby
listed = client.beta.sessions.resources.list(session.id)
repo_resource_id = listed.data.first.id

client.beta.sessions.resources.update(
  repo_resource_id,
  session_id: session.id,
```

```
  authorization_token: "ghp_your_new_github_token"
)
```
</doc>

<doc path="shared/agent-design.md">
Agent Design Patterns

This file covers decision heuristics for building agents on the Claude API: which primitives to reach for, how to design your tool surface, and how to manage context and cost over long runs. For per-tool mechanics and code examples, see `tool-use-concepts.md` and the language-specific folders.

Model Parameters

Parameter	When to use it	What to expect
Adaptive thinking (`thinking: {type: "adaptive"}`)	When you want Claude to control when and how much to think.	Claude determines thinking depth per request and automatically interleaves thinking between tool calls. No token budget to tune.
Effort (`output_config: {effort: ...}`)	When adjusting the tradeoff between thoroughness and token efficiency.	Lower effort -> fewer and more-consolidated tool calls, less preamble, terser confirmations. `medium` is often a favorable balance. Use `max` when correctness matters more than cost.

See `SKILL.md` ?Thinking & Effort for model support and parameter details.

Designing Your Tool Surface

Bash vs. dedicated tools

Claude doesn't know your application's security boundary, approval policy, or UX surface. Claude emits tool calls; your harness handles them. The shape of those tool calls determines what the harness can do.

A **bash tool** gives Claude broad programmatic leverage -- it can perform almost any action. But it gives the harness only an opaque command string, the same shape for every action. Promoting an action to a **dedicated tool** gives the harness an action-specific hook with typed arguments it can intercept, gate, render, or audit.

When to promote an action to a dedicated tool:

- **Security boundary.** Actions that require gating are natural candidates. Reversibility is a useful criterion: hard-to-reverse actions (external API calls, sending messages, deleting data) can be gated behind user confirmation. A `send_email` tool is easy to gate; `bash -c "curl -X POST ..."` is not.
- **Staleness checks.** A dedicated `edit` tool can reject writes if the file changed since Claude last read it. Bash can't enforce that invariant.
- **Rendering.** Some actions benefit from custom UI. Claude Code promotes question-asking to a tool so it can render as a modal, present options, and block the agent loop until answered.
- **Scheduling.** Read-only tools like `glob` and `grep` can be marked parallel-safe. When the same actions run through bash, the harness can't tell a parallel-safe `grep` from a parallel-unsafe `git push`, so it must serialize.

Rule of thumb: Start with bash for breadth. Promote to dedicated tools when you need to gate, render, audit, or parallelize the action.

Anthropic-Provided Tools

Tool	Side	When to use it	What to expect
Bash	Client	Claude needs to execute shell commands.	Claude emits commands; your harness executes them. Reference implementation provided.
Text editor	Client	Claude needs to read or edit files.	Claude views, creates, and edits files via your implementation. Reference implementation provided.
Computer use	Client or Server	Claude needs to interact with GUIs, web apps, or visual interfaces.	Claude takes screenshots and issues mouse/keyboard commands. Can be self-hosted (you run the environment) or Anthropic-hosted.

Code execution	Server	Claude needs to run code in a sandbox you don't want to manage.	Anthropic-hosted container with built-in file and bash sub-tools. No client-side execution.
Web search / fetch	Server	Claude needs information past its training cutoff (news, current events, recent docs) or the content of a specific URL.	Claude issues a query or URL; Anthropic executes it and returns results with citations.
Memory	Client	Claude needs to save context across sessions.	Claude reads/writes a `/memories` directory. You implement the storage backend.

Client-side tools are defined by Anthropic (name, schema, Claude's usage pattern) but executed by your harness. Anthropic provides reference implementations. **Server-side** tools run entirely on Anthropic infrastructure -- declare them in `tools` and Claude handles the rest.

Composing Tool Calls: Programmatic Tool Calling

With standard tool use, each tool call is a round trip: Claude calls the tool, the result lands in Claude's context, Claude reasons about it, then calls the next tool. Three sequential actions (read profile -> look up orders -> check inventory) means three round trips. Each adds latency and tokens, and most of the intermediate data is never needed again.

Programmatic tool calling (PTC) lets Claude compose those calls into a script instead. The script runs in the code execution container. When the script calls a tool, the container pauses, the call is executed (client-side or server-side), and the result returns to the running code -- not to Claude's context. The script processes it with normal control flow (loops, filters, branches). Only the script's final output returns to Claude.

When to use it	What to expect
Many sequential tool calls, or large intermediate results you want filtered before they hit the context window.	Claude writes code that invokes tools as functions. Runs in the code execution container. Token cost scales with final output, not intermediate results.

Scaling the Tool and Instruction Set

Feature	When to use it	What to expect
Tool search	Many tools available, but only a few relevant per request. Don't want all schemas in context upfront.	Claude searches the tool set and loads only relevant schemas. Tool definitions are appended, not swapped -- preserves cache (see Caching below).
Skills	Task-specific instructions Claude should load only when relevant.	Each skill is a folder with a `SKILL.md`. The skill's description sits in context by default; Claude reads the full file when the task calls for it.

Both patterns keep the fixed context small and load detail on demand.

Long-Running Agents: Managing Context

Pattern	When to use it	What to expect
Context editing	Context grows stale over many turns (old tool results, completed thinking).	Tool results and thinking blocks are cleared based on configurable thresholds. Keeps the transcript lean without summarizing.
Compaction	Conversation likely to reach or exceed the context window limit.	Earlier context is summarized into a compaction block server-side. See `SKILL.md` ?Compaction for the critical `response.content` handling.
Memory	State must persist across sessions (not just within one conversation).	Claude reads/writes files in a memory directory. Survives process restarts.

Choosing between them: Context editing and compaction operate within a session -- editing prunes stale turns, compaction summarizes when you're near the limit. Memory is for cross-session persistence. Many long-running agents use all three.

Caching for Agents

```
**Read `prompt-caching.md` first.** It covers the prefix-match invariant, breakpoint placement, the
silent-invalidator audit, and why changing tools or models mid-session breaks the cache. This section covers
only the agent-specific workarounds for those constraints.

| Constraint (from `prompt-caching.md`) | Agent-specific workaround |
| --- | --- |
| Editing the system prompt mid-session invalidates the cache. | Append a `{"role": "system", ...}` message
to `messages[]` instead (no beta header; on supporting models -- see `prompt-caching.md` ? Mid-conversation
system messages). The cached prefix stays intact, and the model treats it as an operator-authority
instruction rather than user text. On models that don't support it, fall back to a `<system-reminder>` text
block in the user turn. |
| Switching models mid-session invalidates the cache. | Spawn a **subagent** with the cheaper model for the
sub-task; keep the main loop on one model. On Managed Agents that is a `multiagent` roster entry -- see
`managed-agents-multiagent.md`. |
| Adding/removing tools mid-session invalidates the cache. | Use **tool search** for dynamic discovery -- it
appends tool schemas rather than swapping them, so the existing prefix is preserved. |

For multi-turn breakpoint placement, use top-level auto-caching -- see `prompt-caching.md` ?Placement
patterns.

---

For live documentation on any of these features, see `live-sources.md`.
</doc>

<doc path="shared/anthropic-cli.md">
# Anthropic CLI (`ant`)

The `ant` CLI exposes every Claude API resource as a shell subcommand. Compared to `curl`: request bodies are
built from typed flags or piped YAML instead of hand-written JSON, `@path` inlines file contents into any
string field, `--transform` extracts fields with a GJSON path (no `jq`), list endpoints auto-paginate (cap
total results with `--max-items N`; `--limit` only sets the server page size), and the `beta:` prefix
auto-sets the right `anthropic-beta` header.

## When to use the CLI vs the SDK

**CLI for the control plane, SDK for the data plane.** Agents and environments are relatively static
resources you define, configure, and debug with `ant` -- check the YAML into your repo, apply from CI,
inspect from a terminal. Sessions are dynamic and driven by your application through the SDK -- create per
task, stream events, react to tool calls, integrate into your product. Both hit the same API; the split is
about where the call lives, not what's possible.

| | Control plane -> `ant` | Data plane -> SDK |
|---|---|---|
| Resources | agents, environments, skills, vaults, files | sessions, events |
| Cadence | Once per deploy / ad-hoc | Every task / every turn |
| Lives in | `*.yaml` in your repo + CI + terminal | Application code |
| Typical calls | `create < agent.yaml`, `update --version N`, `list`, `retrieve`, `archive`, `--debug` |
`sessions.create()`, `events.stream()`, `events.send()` |

## Install and auth

```sh
# macOS
brew install anthropics/tap/ant
xattr -d com.apple.quarantine "$(brew --prefix)/bin/ant"

# Linux / WSL -- pick the release from github.com/anthropics/anthropic-cli/releases
curl -fsSL "https://github.com/anthropics/anthropic-cli/releases/download/v${VERSION}/ant_${VERSION}_$(uname
-s | tr A-Z a-z)_$(uname -m | sed -e s/x86_64/amd64/ -e s/aarch64/arm64/).tar.gz" \
  | sudo tar -xz -C /usr/local/bin ant

# Or from source (Go 1.22+)
go install github.com/anthropics/anthropic-cli/cmd/ant@latest
```

Auth -- the CLI resolves credentials the same way the SDKs do (first match wins): explicit flags, then
`ANTHROPIC_API_KEY`, then `ANTHROPIC_AUTH_TOKEN`, then the `ANTHROPIC_PROFILE`-selected or active profile,
then Workload Identity Federation env vars, then the default profile on disk. Override the host with
```

````
`ANTHROPIC_BASE_URL` or `--base-url`.

- **API key**: set `ANTHROPIC_API_KEY` in the environment.
- **OAuth profile** (no static key to manage): `ant auth login` opens a browser, exchanges for a short-lived token, and stores a profile under `$ANTHROPIC_CONFIG_DIR` (default `~/.config/anthropic/` on Linux/macOS, `%APPDATA%\Anthropic` on Windows -- `configs/<profile>.json` for settings, `credentials/<profile>.json` for tokens). Subsequent `ant` (and SDK) calls pick it up automatically -- a bare `Anthropic()` client works after login, but scripts that read `ANTHROPIC_API_KEY` directly do not. Claude Code and the Claude Agent SDK honor the same profile resolution. `ant auth status` shows which credential source and profile won (it reports status only -- don't script against its exit code as a health check); `ant auth logout` clears the active profile (`--all` for every profile). On a remote host without a browser, `ant auth login --no-browser` prints the authorize URL and accepts the code back in the terminal.
- **Non-interactive workloads** (CI, servers, containers): interactive login is for development on your own machine -- use Workload Identity Federation instead (see the authentication docs via `shared/live-sources.md`).

> **The #1 auth trap:** profiles are only consulted when no API key is set. A stale exported `ANTHROPIC_API_KEY` silently overrides every profile -- requests hit whatever org/workspace that key is scoped to. `ant auth status` shows which source won; unset the key (or per-command: `env -u ANTHROPIC_API_KEY ant ...`) before relying on a profile. Truly **unset** it -- an empty `ANTHROPIC_API_KEY=""` still wins its precedence slot and authenticates with an empty key. The same shadowing applies in reverse to Claude Code: after `ant auth login`, Claude Code may warn about an auth conflict between the profile and its own `/login` credential -- keep one (use the profile and `/logout` in Claude Code, or `ant auth logout` to keep Claude Code's own login).

**Named profiles** -- an interactive-login token is bound to a single org+workspace, and the API only shows resources belonging to that workspace. If an agent, session, or file you created "disappears", the usual cause is a token scoped to a different workspace than the one that created it (`ant auth status` shows the active workspace). Multi-workspace work means one profile per workspace:

```sh
ant auth login --profile <name>                  # creates the profile if it doesn't exist; org/workspace picker in browser
ant auth login --profile <name> --workspace-id wrkspc_01...   # bind directly, skip the picker
ant profile activate <name>                      # switch the default profile
ant --profile <name> models list                 # one-off; equivalent: ANTHROPIC_PROFILE=<name> ant models list
ant profile list                                 # inspect
ant profile set workspace_id wrkspc_01... --profile <name>    # edit config keys (workspace_id, base_url, organization_id, ...)
```

`ant profile set` edits an existing profile's config -- it never creates one, and it does **not** rebind already-issued credentials; run `ant auth login` again under that profile to mint a token for the new target. Pointing `ANTHROPIC_PROFILE` at a profile that doesn't exist is an error, not a fall-through. Refresh tokens eventually hard-expire (they don't slide with use) -- when a previously working profile starts failing auth, re-run `ant auth login` before debugging anything else.

**Scopes** -- a profile's OAuth scope set is requested at login (`--scope`) and persists on the profile (`scope` is also a `profile set` config key; like other config edits, changing it requires a fresh `ant auth login` to take effect). Privileged scopes -- e.g. `org:admin` for organization-administration endpoints -- are **not** in the default scope set: pass the full set you want explicitly (`ant auth login --profile admin --scope "... org:admin"`), and the server grants a privileged scope only if your role actually has it. Because the scope set rides on every token the profile mints, keep privileged work on a dedicated profile (`admin` vs `default`) and do day-to-day inference on the unprivileged one, switching with `--profile`/`ANTHROPIC_PROFILE`. Check `ant auth login --help` for the current scope list, and `ant auth status` to see what the active token carries.

To hand the active credential to a subprocess or raw-HTTP script:

```sh
# Bare access token -- for curl's Authorization header
curl https://api.anthropic.com/v1/messages \
  -H "Authorization: Bearer $(ant auth print-credentials --access-token)" \
  -H "anthropic-version: 2023-06-01" \
  -H "anthropic-beta: oauth-2025-04-20" \
  -H "content-type: application/json" \
  -d '{"model": "claude-opus-5", "max_tokens": 1024, "messages": [{"role": "user", "content": "Hello"}]}'

# .env format -- sets ANTHROPIC_AUTH_TOKEN (and ANTHROPIC_BASE_URL if the profile has one).
````
````

```
# Output is bare KEY=value (no `export`), so use `set -a` to auto-export for child processes:
set -a; eval "$(ant auth print-credentials --env)"; set +a
python my_script.py   # SDK picks up ANTHROPIC_AUTH_TOKEN
```

OAuth tokens go on `Authorization: Bearer` (not `x-api-key:`) **plus the `anthropic-beta: oauth-2025-04-20` header** -- converting a raw curl/httpx script from an API key is a header change, not a key swap. The beta header requirement is endpoint-dependent (some endpoints happen to work without it; `/v1/messages` does not) -- always send it so requests don't break when you switch endpoints. The token is short-lived and not auto-refreshed when passed via env var, so re-run `print-credentials` before it expires for long-running scripts (`print-credentials` itself refreshes the token if needed). If both `ANTHROPIC_API_KEY` and `ANTHROPIC_AUTH_TOKEN` are set, the SDKs send both and the API rejects the request -- unset `ANTHROPIC_API_KEY` before `eval`ing the `--env` output.

Foot-gun: `ant auth print-credentials` with **no flags** prints the entire credentials JSON, not the bare token -- putting that in an `Authorization` header yields an empty response or HTTP/2 protocol error. Always use `--access-token` for headers (it always reads the named/active profile; a set `ANTHROPIC_API_KEY` doesn't override credential printing).

Command structure

```
ant <resource>[:<subresource>] <action> [flags]
```

Beta resources (agents, sessions, environments, deployments, skills, vaults, memory stores) live under `beta:` -- the CLI auto-sends the right `anthropic-beta` header, so don't pass it yourself unless overriding with `--beta <header>`. For self-hosted environments, `ant beta:worker poll/run` and `ant beta:environments:work stats/stop` drive and monitor the work queue -- see `shared/managed-agents-self-hosted-sandboxes.md`.

```sh
ant models list
ant messages create --model claude-opus-5 --max-tokens 1024 --message '{role: user, content: "Hello"}'
ant beta:agents retrieve --agent-id agent_01...
ant beta:sessions:events list --session-id session_01...
```

`ant --help` lists resources; append `--help` to any subcommand for its flags.

Global flags

Flag	Purpose
`--format`	`auto` (default: pretty if TTY, compact if piped), `json`, `jsonl`, `yaml`, `pretty`, `raw`, `explore` (interactive TUI)
`--transform`	GJSON path applied to the response (per-item on list endpoints). Not applied when `--format raw`.
`-r`, `--raw-output`	If the transformed result is a string, print it without quotes (jq semantics). Pair with `--transform` for scalar capture.
`--max-items`	Cap total results returned from auto-paginating list endpoints (distinct from `--limit`, which is the server page size).
`--format-error` / `--transform-error`	Same as `--format`/`--transform`, applied to error responses. `-r` does not apply to the error path -- use `--format-error yaml` for unquoted error scalars.
`--base-url`	Override API host
`--debug`	Print full HTTP request + response to stderr (API key redacted)

Output -- `--transform` + `--format`

`--transform` takes a [GJSON path](https://github.com/tidwall/gjson/blob/master/SYNTAX.md). On list endpoints it runs **per item**, not on the envelope.

```sh
ant beta:agents list --transform '{id,name,model}' --format jsonl
```

Extract a scalar for shell use: pair `--transform` with `-r` (`--raw-output` -- prints strings unquoted, jq-style):

```sh
```

```
AGENT_ID=$(ant beta:agents create --name "My Agent" --model '{id: claude-sonnet-5}' \
  --transform id -r)
```

Input -- flags, stdin, `@file`

Flags -- scalar fields map directly. Structured fields accept relaxed-YAML syntax (unquoted keys) or strict JSON. Repeatable flags build arrays (each `--tool`, `--event`, `--message` appends one element):

```sh
ant beta:agents create \
  --name "Research Agent" \
  --model '{id: claude-opus-5}' \
  --tool '{type: agent_toolset_20260401}' \
  --tool '{type: custom, name: search_docs, input_schema: {type: object, properties: {query: {type: string}}}}'
```

Stdin -- pipe a full JSON or YAML body. Merged with flags; flags win on conflict (for array fields, any flag **replaces** the stdin array entirely -- it does not append). Quote the heredoc delimiter (`<<'YAML'`) to disable shell expansion inside the body:

```sh
ant beta:agents create <<'YAML'
name: Research Agent
model: claude-opus-5
system: |
  You are a research assistant. Cite sources for every claim.
tools:
  - type: agent_toolset_20260401
YAML
```

`@file` references -- inline a file's contents into any string-valued field. Inside structured flag values, quote the path. Binary files are auto-base64'd; force with `@file://` (text) or `@data://` (base64). Escape a literal leading `@` as `\@`.

```sh
ant beta:agents create --name "Researcher" --model '{id: claude-sonnet-5}' --system @./prompts/researcher.txt

ant messages create --model claude-opus-5 --max-tokens 1024 \
  --message '{role: user, content: [
    {type: document, source: {type: base64, media_type: application/pdf, data: "@./scan.pdf"}},
    {type: text, text: "Extract the text from this scanned document."}
  ]}' \
  --transform 'content.0.text' -r
```

Flags that natively take a file path (e.g. `--file` on `beta:files upload`) accept a bare path without `@`.

Version-controlled Managed Agents resources

This is the recommended flow for defining agents and environments -- check the YAML into your repo and sync via `create` (first time) / `update` (thereafter). See `shared/managed-agents-core.md` for the field reference.

```yaml
# summarizer.agent.yaml
name: Summarizer
model: claude-sonnet-5
system: |
  You are a helpful assistant that writes concise summaries.
tools:
  - type: agent_toolset_20260401
```

```sh
# Create (once) -- capture the ID
AGENT_ID=$(ant beta:agents create < summarizer.agent.yaml --transform id -r)
```

```
# Update (CI) -- needs ID + current version (optimistic lock)
ant beta:agents update --agent-id "$AGENT_ID" --version 1 < summarizer.agent.yaml
```

Same pattern for environments (`ant beta:environments create|update < env.yaml`), then start a session with both IDs:

```sh
ant beta:sessions create --agent "$AGENT_ID" --environment-id "$ENV_ID" --title "Task"
ant beta:sessions:events send --session-id "$SID" \
  --event '{type: user.message, content: [{type: text, text: "Summarize X"}]}'
ant beta:sessions:events list --session-id "$SID" --transform 'content.0.text' -r
ant beta:sessions:events stream --session-id "$SID"   # live event stream
```

Interactive session loop (stream-before-send)

`ant beta:sessions:events stream` only delivers events emitted *after* the stream opens -- so open it **before** sending the kickoff to avoid missing early events. Use process substitution to hold the stream on a file descriptor, send, then read:

```sh
exec {stream}< <(ant beta:sessions:events stream --session-id "$SID" \
  --transform '{type,text:content.#(type=="text").text,err:error.message}' --format yaml)

ant beta:sessions:events send --session-id "$SID" > /dev/null <<'YAML'
events:
  - type: user.message
    content:
      - type: text
        text: Summarize the repo README
YAML

type=
while IFS= read -r -u "$stream" line; do
  case "$line" in
    type:\ session.status_idle) break ;;
    type:\ session.error)
      IFS= read -r -u "$stream" next || next=
      case "$next" in err:\ *) msg=${next#err: } ;; *) msg=unknown ;; esac
      printf '\n[Error: %s]\n' "$msg"; break ;;
    type:\ *) type=${line#type: } ;;
    text:*)
      [[ $type == agent.message ]] || continue
      val=${line#text: }
      case "$val" in '|-'|'|') ;; *) printf '%s' "$val" ;; esac ;;
    \ \ *)
      if [[ $type == agent.message ]]; then printf '%s\n' "${line#  }"; fi ;;
  esac
done
exec {stream}<&-
```

This works for interactive exploration and demos. For application code that needs to react to `agent.tool_use` / `agent.custom_tool_use` events, reconnect after drops, or dedup against `events.list`, use the SDK -- see `shared/managed-agents-client-patterns.md`.

Scripting patterns

`--transform id -r` on a list endpoint emits one bare ID per line -- compose with `xargs`, or use `--max-items N` to bound the result set without piping through `head`:

```sh
FIRST=$(ant beta:agents list --transform id -r --max-items 1)
ant beta:agents:versions list --agent-id "$FIRST" --transform '{version,created_at}' --format jsonl
```

Error shaping mirrors the success path (note: `-r` does not apply to error output -- use `--format-error yaml` for an unquoted scalar here):

```sh
ant beta:agents retrieve --agent-id bogus --transform-error error.message --format-error yaml 2>&1
```

Shell completion: `ant @completion {zsh|bash|fish|powershell}`.

For the full, always-current reference (including per-endpoint flags), WebFetch the **Anthropic CLI** URL in `shared/live-sources.md`.
</doc>

<doc path="shared/claude-platform-on-aws.md">
Claude Platform on AWS

Anthropic-operated access to the Claude Developer Platform through AWS infrastructure -- SigV4 authentication, AWS IAM access control, and AWS Marketplace billing. Because Anthropic operates it, **the API surface matches first-party with same-day parity** -- for per-feature exceptions, see `shared/platform-availability.md` (the single source of truth; do not rely on an inline exception list here). Model IDs are the bare first-party strings (`claude-opus-5`, `claude-sonnet-5`) -- **no provider prefix**.

> **Not the same as Amazon Bedrock.** Bedrock is partner-operated (AWS runs the service; release schedules vary, feature subset, `anthropic.`-prefixed model IDs). Claude Platform on AWS and Bedrock coexist; pick by whether you need AWS-native IAM/billing with full Anthropic API parity (this page) vs. Bedrock's own ecosystem.

Client & install

Language	Install	Client
Python	`pip install -U "anthropic[aws]"`	`from anthropic import AnthropicAWS` -> `AnthropicAWS()`
TypeScript	`npm install @anthropic-ai/aws-sdk`	`import AnthropicAws from "@anthropic-ai/aws-sdk"` -> `new AnthropicAws()`
Go	`go get github.com/anthropics/anthropic-sdk-go`	`import anthropicaws "github.com/anthropics/anthropic-sdk-go/aws"` -> `anthropicaws.NewClient(ctx, anthropicaws.ClientConfig{})`
C#	`dotnet add package Anthropic.Aws`	`new AnthropicAwsClient()`
Java	See SDK repo in `shared/live-sources.md`	See SDK repo in `shared/live-sources.md`
Ruby	`gem install anthropic aws-sdk-core`	See SDK repo in `shared/live-sources.md`
PHP	`composer require anthropic-ai/sdk aws/aws-sdk-php`	See SDK repo in `shared/live-sources.md`

After construction, **use the client exactly as you would `Anthropic()`** -- `client.messages.create(...)`, `client.beta.sessions.*`, etc., with bare model IDs.

```python
from anthropic import AnthropicAWS

client = AnthropicAWS()  # region + workspace_id from env; see below
client.messages.create(
    model="claude-opus-5",
    max_tokens=1024,
    messages=[{"role": "user", "content": "Hello"}],
)
```

Required configuration

Two values must be available (constructor args or environment) -- **there is no default fallback** for either:

Value	Env var	Notes
AWS region	`AWS_REGION`	Required. Unlike `AnthropicBedrock`, there is no `us-east-1` fallback.
Workspace ID	`ANTHROPIC_AWS_WORKSPACE_ID`	Required. Routes requests to your Claude workspace.

Endpoint pattern: `https://aws-external-anthropic.{region}.api.aws/v1/...`. Requests are SigV4-signed with service name `aws-external-anthropic`.

Authentication

````
The client resolves AWS credentials via the standard precedence chain: explicit constructor args ->
environment (`AWS_ACCESS_KEY_ID`/`AWS_SECRET_ACCESS_KEY`/`AWS_SESSION_TOKEN`) -> shared profile -> assumed
role / instance metadata.

**Short-term API keys** are also supported for cases where SigV4 isn't practical (e.g., browser, simple
scripts). Mint one with the per-language token-generator package; pass it as `api_key` on the client.
Lifetime is the **lesser of** the requested duration, the underlying credential's expiry, and **12 hours**.
For package names and IAM details, WebFetch the Claude Platform on AWS page in `shared/live-sources.md`.

---

## What to tell users

- Treat it as first-party: every section of this skill applies unchanged. Do **not** apply Bedrock's
feature-availability mask.
- Model IDs are bare (`claude-opus-5`). Do **not** add an `anthropic.` prefix.
- A missing region or `workspace_id` throws at client-construction time (no request is sent). A **403** means
the request reached the server -- check for a **wrong** `workspace_id` or a missing IAM action on the
principal. See the IAM actions reference in `shared/live-sources.md`.
</doc>

<doc path="shared/error-codes.md">
# HTTP Error Codes Reference

This file documents HTTP error codes returned by the Claude API, their common causes, and how to handle them.
For language-specific error handling examples, see the `python/` or `typescript/` folders.

## Error Code Summary

| Code | Error Type              | Retryable | Common Cause                          |
| ---- | ----------------------- | --------- | ------------------------------------- |
| 400  | `invalid_request_error` | No        | Invalid request format or parameters |
| 401  | `authentication_error`  | No        | Invalid or missing API key            |
| 403  | `permission_error`      | No        | API key lacks permission              |
| 404  | `not_found_error`       | No        | Invalid endpoint or model ID          |
| 413  | `request_too_large`     | No        | Request exceeds size limits           |
| 429  | `rate_limit_error`      | Yes       | Too many requests                     |
| 500  | `api_error`             | Yes       | Anthropic service issue               |
| 529  | `overloaded_error`      | Yes       | API is temporarily overloaded         |

## Detailed Error Information

### 400 Bad Request

**Causes:**

- Malformed JSON in request body
- Missing required parameters (`model`, `max_tokens`, `messages`)
- Invalid parameter types (e.g., string where integer expected)
- Empty messages array
- Messages not alternating user/assistant

**Example error:**

```json
{
  "type": "error",
  "error": {
    "type": "invalid_request_error",
    "message": "messages: roles must alternate between \"user\" and \"assistant\""
  },
  "request_id": "req_011CSHoEeqs5C35K2UUqR7Fy"
}
```

**Fix:** Validate request structure before sending. Check that:

- `model` is a valid model ID
- `max_tokens` is a positive integer
- `messages` array is non-empty and alternates correctly
````

```
---

### 401 Unauthorized

**Causes:**

- Missing `x-api-key` header or `Authorization` header
- Invalid API key format
- Revoked or deleted API key
- OAuth bearer token sent via `x-api-key` instead of `Authorization: Bearer`
- Both `ANTHROPIC_API_KEY` and `ANTHROPIC_AUTH_TOKEN` set -- the SDK sends both headers and the API rejects
the request

**Fix:** Set `ANTHROPIC_API_KEY`, or run `ant auth login` and leave the client constructor empty. For raw
HTTP with an OAuth token, use `Authorization: Bearer <token>` (not `x-api-key:`).

---

### 403 Forbidden

**Causes:**

- API key doesn't have access to the requested model
- Organization-level restrictions
- Attempting to access beta features without beta access

**Fix:** Check your API key permissions in the Console. You may need a different API key or to request access
to specific features.

---

### 404 Not Found

**Causes:**

- Typo in model ID (e.g., `claude-sonnet-4.6` instead of `claude-sonnet-4-6`)
- Using deprecated model ID
- Invalid API endpoint

**Fix:** Use exact model IDs from the models documentation. You can use aliases (e.g., `claude-opus-5`).

---

### 413 Request Too Large

**Causes:**

- Request body exceeds maximum size
- Too many tokens in input
- Image data too large

**Fix:** Reduce input size -- truncate conversation history, compress/resize images, or split large documents
into chunks.

---

### 400 Validation Errors

Some 400 errors are specifically related to parameter validation:

- `max_tokens` exceeds model's limit
- Invalid `temperature` value (must be 0.0-1.0)
- `budget_tokens` >= `max_tokens` in extended thinking
- Invalid tool definition schema

**Model-specific 400s on Claude Opus 5 / Fable 5 / Opus 4.8 / 4.7:**

- `temperature`, `top_p`, `top_k` are removed -- sending any of them returns 400. Delete the parameter; see
`shared/model-migration.md` -> Per-SDK Syntax Reference.
```

```
- `thinking: {type: "enabled", budget_tokens: N}` is removed -- sending it returns 400. Use `thinking: {type:
"adaptive"}` instead.
- **Claude Opus 5:** `thinking: {type: "disabled"}` returns 400 when `effort` is `xhigh` or `max` -- it is
accepted at `high` or below. Thinking is on by default, so omitting the param runs adaptive rather than
disabling it.
- **Fable 5 only:** an explicit `thinking: {type: "disabled"}` returns 400 at any effort (it is accepted on
Opus 4.8/4.7). Omit the `thinking` param entirely instead.
- **Fable 5 only:** if the organization is set to zero data retention (ZDR) -- or any retention below the
required 30 days -- then **all** Fable 5 requests return `400 invalid_request_error`, even with a perfectly
valid payload. Check the org's retention configuration before debugging the request body.

**Common mistake with extended thinking on older models (Opus 4.6 and earlier):**

```
# Wrong: budget_tokens must be < max_tokens
thinking: budget_tokens=10000, max_tokens=1000  -> Error!

# Correct
thinking: budget_tokens=10000, max_tokens=16000
```

---

429 Rate Limited

Causes:

- Exceeded requests per minute (RPM)
- Exceeded tokens per minute (TPM)
- Exceeded tokens per day (TPD)

Headers to check:

- `retry-after`: Seconds to wait before retrying
- `x-ratelimit-limit-*`: Your limits
- `x-ratelimit-remaining-*`: Remaining quota

Fix: The Anthropic SDKs automatically retry 429 and 5xx errors with exponential backoff (default:
`max_retries=2`). For custom retry behavior, see the language-specific error handling examples.

---

500 Internal Server Error

Causes:

- Temporary Anthropic service issue
- Bug in API processing

Fix: Retry with exponential backoff. If persistent, check
status.anthropic.com.

---

529 Overloaded

Causes:

- High API demand
- Service capacity reached

Fix: Retry with exponential backoff. Consider using a different model (Haiku is often less loaded),
spreading requests over time, or implementing request queuing.

Common Mistakes and Fixes

| Mistake | Error | Fix
|
```

```
| ------------------------------ | ---------------- |
------------------------------------------------------ |
| `temperature`/`top_p`/`top_k` on Claude Opus 5 / Fable 5 / Opus 4.8 / 4.7 | 400 | Remove the parameter (see
`shared/model-migration.md`)  |
| `budget_tokens` on Claude Opus 5 / Fable 5 / Opus 4.8 / 4.7 | 400  | Use `thinking: {type: "adaptive"}`
|
| `thinking: {type: "disabled"}` on Fable 5 | 400    | Omit the `thinking` param entirely (accepted on Opus
4.8/4.7) |
| Org set to ZDR / retention below 30 days (Fable 5) | 400 on every request | Fix the org's data-retention
configuration -- the payload isn't the problem |
| `budget_tokens` >= `max_tokens` (older models) | 400 | Ensure `budget_tokens` < `max_tokens`
|
| Typo in model ID                | 404              | Use valid model ID like `claude-opus-5`               |
| First message is `assistant`    | 400              | First message must be `user`
|
| Consecutive same-role messages  | 400              | Alternate `user` and `assistant`
|
| API key in code                 | 401 (leaked key) | Use environment variable
|
| Custom retry needs              | 429/5xx          | SDK retries automatically; customize with
`max_retries` |

## Typed Exceptions in SDKs

**Always use the SDK's typed exception classes** instead of checking error messages with string matching.
Each HTTP status code maps to a specific exception class per SDK.

### Exception class names by language

| HTTP | Python (`anthropic.*`) / TypeScript (`Anthropic.*`) | Ruby (`Anthropic::Errors::*`) | Java
(`com.anthropic.errors.*`) | C# | PHP (`Anthropic\Core\Exceptions\*`) |
|---|---|---|---|---|---|
| 400 | `BadRequestError` | `BadRequestError` | `BadRequestException` | `AnthropicBadRequestException` |
`BadRequestException` |
| 401 | `AuthenticationError` | `AuthenticationError` | `UnauthorizedException` |
`AnthropicUnauthorizedException` | `AuthenticationException` |
| 403 | `PermissionDeniedError` | `PermissionDeniedError` | `PermissionDeniedException` |
`AnthropicForbiddenException` | `PermissionDeniedException` |
| 404 | `NotFoundError` | `NotFoundError` | `NotFoundException` | `AnthropicNotFoundException` |
`NotFoundException` |
| 422 | `UnprocessableEntityError` | `UnprocessableEntityError` | `UnprocessableEntityException` |
`AnthropicUnprocessableEntityException` | `UnprocessableEntityException` |
| 429 | `RateLimitError` | `RateLimitError` | `RateLimitException` | `AnthropicRateLimitException` |
`RateLimitException` |
| >=500 | `InternalServerError` | `InternalServerError` | `InternalServerException` | `Anthropic5xxException`
| `InternalServerException` |
| net | `APIConnectionError` | `APIConnectionError` | `AnthropicIoException` | `AnthropicIOException` |
`APIConnectionException` |
| base | `APIError` (both); `APIStatusError` (Python only) | `APIStatusError` / `APIError` |
`AnthropicServiceException` | `AnthropicApiException` | `APIStatusException` / `APIException` |

The Ruby and PHP classes live in a dedicated errors namespace -- write `Anthropic::Errors::RateLimitError`
and `Anthropic\Core\Exceptions\RateLimitException` (not bare `Anthropic::RateLimitError`). All 4xx C#
exceptions also inherit from `Anthropic4xxException`.

### Catch most-specific first, in a chain

Order `catch`/`except`/`rescue` clauses from the most specific subclass to the base class, with a separate
clause for each category you handle differently -- retryable (429, >=500, network) vs. non-retryable (4xx).
The SDK defines a distinct class per status for exactly this reason; a single broad catch-all discards that
information.

```python
try:
    msg = client.messages.create(...)
except anthropic.NotFoundError as e:          # 404 -- e.g. bad model ID
    ...
except anthropic.RateLimitError as e:         # 429 -- back off and retry
    ...
except anthropic.APIStatusError as e:         # any other non-2xx HTTP response
```
```

```
    print(e.status_code, e.message)
except anthropic.APIConnectionError as e:     # network failure before a response
    ...
```

The same chain shape applies in every SDK: TypeScript `instanceof Anthropic.NotFoundError` -> `RateLimitError` -> `APIConnectionError` -> `APIError` (check `APIConnectionError` before `APIError` -- in the TypeScript SDK it's a subclass of `APIError`, unlike Python where it's a sibling); Ruby `rescue Anthropic::Errors::NotFoundError` -> `...::RateLimitError` -> `...::APIStatusError`; Java `catch (NotFoundException) ... catch (RateLimitException) ... catch (AnthropicServiceException)`; C# `catch (AnthropicNotFoundException) ... catch (AnthropicRateLimitException) ... catch (AnthropicApiException)`; PHP `catch (NotFoundException) ... catch (RateLimitException) ... catch (APIStatusException)`.

Go -- `errors.As` then branch on status

The Go SDK returns a single `*anthropic.Error` for all non-2xx responses. Unwrap it with `errors.As`, then branch on `StatusCode`:

```go
_, err := client.Messages.New(ctx, params)
if err != nil {
    var apierr *anthropic.Error
    if errors.As(err, &apierr) {
        switch apierr.StatusCode {
        case 404:
            // bad model ID / resource
        case 429:
            // back off and retry
        default:
            // other API error -- apierr.StatusCode, apierr.RequestID
        }
    } else {
        // transport-level error (*url.Error wrapping *net.OpError, etc.)
    }
}
```

Error `.type` Field

All `APIStatusError` subclasses now expose a `.type` property (Python: `.type`, TypeScript: `.type`, Java: `.errorType()`, Go: `.Type()`, Ruby: `.type`, PHP: `.type`) that returns the API error type string (e.g., `"invalid_request_error"`, `"authentication_error"`, `"rate_limit_error"`, `"overloaded_error"`). Use this for programmatic error classification when you need finer granularity than the HTTP status code -- for example, distinguishing `"billing_error"` from `"permission_error"` (both map to 403).

```python
except anthropic.APIStatusError as e:
    if e.type == "rate_limit_error":
        # handle rate limiting
    elif e.type == "overloaded_error":
        # handle overload
```

"Extract memory resource shape, scoping, and lifecycle"                                         |
| Onboarding            | `https://platform.claude.com/docs/en/managed-agents/onboarding.md`               |
"Extract first-run setup, prerequisites, and account/region requirements"                       |
| Cloud Containers      | `https://platform.claude.com/docs/en/managed-agents/cloud-containers.md`         |
"Extract cloud container runtime, image config, and network/storage knobs"                      |
| Migration             | `https://platform.claude.com/docs/en/managed-agents/migration.md`                |
"Extract migration paths from earlier APIs/preview shapes to GA managed agents"                 |

### Anthropic CLI

The `ant` CLI provides terminal access to the Claude API. Every API resource is exposed as a subcommand. It
is the recommended way to create agents and environments from version-controlled YAML (`ant beta:agents
create < agent.yaml` -- see `shared/anthropic-cli.md`), and also exposes sessions and every other API
resource for scripting and interactive inspection.

| Topic         | URL                                                          | Extraction Prompt
|
| ------------- | ------------------------------------------------------------ |
------------------------------------------------------------------------------------------ |
| Anthropic CLI | `https://platform.claude.com/docs/en/api/sdks/cli.md`   | "Extract CLI install,
authentication, command structure, and the beta:agents/environments/sessions commands" |
| Authentication overview | `https://platform.claude.com/docs/en/manage-claude/authentication.md` | "Extract
the credential options (API keys, interactive OAuth login, Workload Identity Federation) and when to use
each" |
| WIF reference | `https://platform.claude.com/docs/en/manage-claude/wif-reference.md`  | "Extract credential
precedence order, the profile configuration file schema, and the configuration directory layout" |

---

## Claude API SDK Repositories

WebFetch these when a binding (class, method, namespace, field) isn't covered in the cached `{lang}/` skill
files or in the managed-agents docs above. The SDKs include beta managed-agents support for `/v1/agents`,
`/v1/sessions`, `/v1/environments`, and related resources -- search the repo for `BetaManagedAgents`,
`beta.agents`, `beta.sessions`, or the equivalent namespace for that language.

| SDK        | URL                                                      | Extraction Prompt
|
| ---------- | -------------------------------------------------------- |
------------------------------------------------------------------------------------------------------------
--------- |
| Python     | `https://github.com/anthropics/anthropic-sdk-python`     | "Extract beta managed-agents
namespaces, classes, and method signatures (`client.beta.agents`, `client.beta.sessions`)" |
| TypeScript | `https://github.com/anthropics/anthropic-sdk-typescript` | "Extract beta managed-agents
namespaces, classes, and method signatures (`client.beta.agents`, `client.beta.sessions`)" |
| Java       | `https://github.com/anthropics/anthropic-sdk-java`       | "Extract beta managed-agents
```

```
classes, builders, and method signatures (`client.beta().agents()`, `BetaManagedAgents*`)" |
| Go         | `https://github.com/anthropics/anthropic-sdk-go`         | "Extract beta managed-agents types
and method signatures (`client.Beta.Agents`, `BetaManagedAgents*` event types)"      |
| Ruby       | `https://github.com/anthropics/anthropic-sdk-ruby`       | "Extract beta managed-agents
methods and parameter shapes (`client.beta.agents`, `client.beta.sessions`)"               |
| C#         | `https://github.com/anthropics/anthropic-sdk-csharp`     | "Extract beta managed-agents
classes and method signatures (NuGet package, `BetaManagedAgents*` types)"                 |
| PHP        | `https://github.com/anthropics/anthropic-sdk-php`        | "Extract beta managed-agents
classes and method signatures (`$client->beta->agents`, `BetaManagedAgents*` params)"      |

Each SDK repo also ships runnable programs under `examples/` -- including the refusal-fallback / `fallbacks`
examples (client-side middleware registration, fallback state, server-side `fallbacks` param). Fetch those
for exact per-language syntax instead of translating another language's example.

---

## Fallback Strategy

If WebFetch fails (network issues, URL changed):

1. Use cached content from the language-specific files (note the cache date)
2. Inform user the data may be outdated
3. Suggest they check platform.claude.com or the GitHub repos directly
</doc>

<doc path="shared/managed-agents-api-reference.md">
# Managed Agents -- Endpoint Reference

All endpoints require `x-api-key` and `anthropic-version: 2023-06-01` headers. Managed Agents endpoints
additionally require the `anthropic-beta` header.

> Most users should define agents and environments as version-controlled YAML applied with the `ant` CLI --
see `shared/anthropic-cli.md`. The endpoints below are the underlying API that the CLI and SDKs drive.

## Beta Headers

```
anthropic-beta: managed-agents-2026-04-01
```

The SDK adds this header automatically for all
`client.beta.{agents,environments,sessions,vaults,memory_stores,deployments,deployment_runs}.*` calls. Skills
endpoints use `skills-2025-10-02`; Files endpoints use `files-api-2025-04-14`.

SDK Method Reference

All resources are under the `beta` namespace. Python and TypeScript share identical method names.

Resource	Python / TypeScript (`client.beta.*`)	Go (`client.Beta.*`)
Agents	`agents.create` / `retrieve` / `update` / `list` / `archive`	`Agents.New` / `Get` / `Update` /
`List` / `Archive`
Agent Versions	`agents.versions.list`	`Agents.Versions.List`
Environments	`environments.create` / `retrieve` / `update` / `list` / `delete` / `archive`
`Environments.New` / `Get` / `Update` / `List` / `Delete` / `Archive`
Environment Work (self-hosted)	`environments.work.poller` / `stats` / `stop`	See
`shared/managed-agents-self-hosted-sandboxes.md`
Sessions	`sessions.create` / `retrieve` / `update` / `list` / `delete` / `archive`	`Sessions.New` /
`Get` / `Update` / `List` / `Delete` / `Archive`
Session Events	`sessions.events.list` / `send` / `stream`	`Sessions.Events.List` / `Send` /
`StreamEvents`
Session Threads	`sessions.threads.list` / `retrieve` / `archive`; `sessions.threads.events.list` /
`stream`	`Sessions.Threads.List` / `Get` / `Archive`; `Sessions.Threads.Events.List` / `StreamEvents`
Session Resources	`sessions.resources.add` / `retrieve` / `update` / `list` / `delete`
`Sessions.Resources.Add` / `Get` / `Update` / `List` / `Delete`
Deployments	`deployments.create` / `update` / `pause` / `unpause` / `archive` / `run`	Not yet
documented -- WebFetch the SDK repo (`shared/live-sources.md`)
Deployment Runs	`deployment_runs.list` / `retrieve` (TS: `deploymentRuns.*`)	Not yet documented --
```

```
WebFetch the SDK repo (`shared/live-sources.md`) |
| Vaults | `vaults.create` / `retrieve` / `update` / `list` / `delete` / `archive` | `Vaults.New` / `Get` /
`Update` / `List` / `Delete` / `Archive` |
| Credentials | `vaults.credentials.create` / `retrieve` / `update` / `list` / `delete` / `archive` /
`mcp_oauth_validate` | `Vaults.Credentials.New` / `Get` / `Update` / `List` / `Delete` / `Archive` /
`McpOauthValidate` |
| Memory Stores | `memory_stores.create` / `retrieve` / `update` / `list` / `delete` / `archive` |
`MemoryStores.New` / `Get` / `Update` / `List` / `Delete` / `Archive` |
| Memories | `memory_stores.memories.create` / `retrieve` / `update` / `list` / `delete` |
`MemoryStores.Memories.New` / `Get` / `Update` / `List` / `Delete` |
| Memory Versions | `memory_stores.memory_versions.list` / `retrieve` / `redact` |
`MemoryStores.MemoryVersions.List` / `Get` / `Redact` |

**Naming quirks to watch for:**
- Agents and Session Threads have **no delete** -- only `archive`. Archive is **permanent**: the agent
becomes read-only, new sessions cannot reference it, and there is no unarchive. Confirm with the user before
archiving a production agent. Environments, Sessions, Vaults, Credentials, and Memory Stores have both
`delete` and `archive`; Session Resources, Files, Skills, and Memories are `delete`-only; Memory Versions
have neither -- only `redact`.
- Session resources use `add` (not `create`).
- Go's event stream is `StreamEvents` (not `Stream`).
- The self-hosted worker is **not** under `client.beta.*` -- it's `EnvironmentWorker` from
`anthropic.lib.environments` / `@anthropic-ai/sdk/helpers/beta/environments`; only
`environments.work.poller/stats/stop` are client methods.

**Agent shorthand:** `agent` on session create accepts three forms -- a bare string (`agent="agent_abc123"`,
latest version), a pinned reference `{type: "agent", id, version}`, or `{type: "agent_with_overrides", id,
version?, model?, system?, tools?, mcp_servers?, skills?}` to override those fields for this session only
(see `shared/managed-agents-core.md` -> Override agent configuration for a session).

**Model shorthand:** `model` on agent create accepts either a bare string (`model="claude-opus-5"` -- uses
`standard` speed) or the full config object, which takes `speed`, `effort`, and `inference_geo` alongside
`id`: `{id: "claude-opus-5", speed: "fast"}`, `{id: "claude-opus-5", effort: "high"}`, `{id: "claude-opus-5",
inference_geo: "us"}`. `effort` accepts a level string (`low`/`medium`/`high`/`xhigh`/`max`) or `{type:
"<level>"}`, and is **agent-configuration only** -- an `effort` inside a per-session `model` override is
ignored. `inference_geo` (`"us"` | `"global"`) pins the geography serving the agent's model requests, and
unlike `effort` **is** applied in a per-session `model` override. See `shared/managed-agents-core.md` ->
Effort on the agent model / Pinning inference geography. Note: `speed: "fast"` is supported on Claude Opus 5
and Opus 4.8 -- on the Claude API only, which includes Managed Agents but not Amazon Bedrock, Google Cloud,
or Microsoft Foundry. Opus 4.7 fast mode has been removed; `speed: "fast"` on Opus 4.7 returns an error.

---

## Agents

**Step one of every flow.** Sessions require a pre-created agent -- there is no inline agent config under
`managed-agents-2026-04-01`.

| Method   | Path                                                | Operation        | Description
|
| -------- | --------------------------------------------------- | ---------------- |
---------------------------------------- |
| `GET` | `/v1/agents` | ListAgents | List agents |
| `POST` | `/v1/agents` | CreateAgent | Create a saved agent configuration |
| `GET` | `/v1/agents/{agent_id}` | GetAgent | Get agent details |
| `POST` | `/v1/agents/{agent_id}` | UpdateAgent | Update agent configuration. `version` is **optional**:
supply it (>= 1) for optimistic concurrency -- a mismatch returns 409 -- or omit it for an unconditional
last-write-wins update. |
| `POST` | `/v1/agents/{agent_id}/archive` | ArchiveAgent | Archive an agent. Makes it **read-only**;
existing sessions continue, new sessions cannot reference it. No unarchive -- this is the terminal state. |
| `GET` | `/v1/agents/{agent_id}/versions` | ListAgentVersions | List agent versions |

## Sessions

| Method   | Path                                                | Operation        | Description
|
| -------- | --------------------------------------------------- | ---------------- |
---------------------------------------- |
| `GET` | `/v1/sessions` | ListSessions | List sessions (paginated) |
| `POST` | `/v1/sessions` | CreateSession | Create a new session |
```

```
| `GET` | `/v1/sessions/{session_id}` | GetSession | Get session details |
| `POST` | `/v1/sessions/{session_id}` | UpdateSession | Update session `metadata`/`title`,
`agent.tools`/`agent.mcp_servers` (session-local override; session must be `idle`), or `budget` -- change the
cap (higher or lower; the new value must exceed the consumed list cost) or remove it with `null`; removal is
one-way, and a budget can never be added post-create. `vault_ids` is create-only (rejected on update). See
`shared/managed-agents-core.md` -> Updating the agent configuration mid-session / Session budgets. |
| `DELETE` | `/v1/sessions/{session_id}` | DeleteSession | Delete a session |
| `POST` | `/v1/sessions/{session_id}/archive` | ArchiveSession | Archive a session |

## Events

| Method   | Path                                                | Operation        | Description
|
| -------- | --------------------------------------------------- | ---------------- |
--------------------------------------- |
| `GET` | `/v1/sessions/{session_id}/events` | ListEvents | List events (polling, paginated) |
| `POST` | `/v1/sessions/{session_id}/events` | SendEvents | Send events (user message, tool result) |
| `GET` | `/v1/sessions/{session_id}/events/stream` | StreamEvents | Stream events via SSE. Optional
`event_deltas[]=agent.message` / `agent.thinking` opts in to live-preview `event_start`/`event_delta` events
-- see `shared/managed-agents-events.md` ? Live previews. |

## Session Threads

Per-subagent event streams in multiagent sessions. See `shared/managed-agents-multiagent.md`.

| Method   | Path                                                | Operation        | Description
|
| -------- | --------------------------------------------------- | ---------------- |
--------------------------------------- |
| `GET` | `/v1/sessions/{session_id}/threads` | ListThreads | List threads (paginated) |
| `GET` | `/v1/sessions/{session_id}/threads/{thread_id}` | GetThread | Retrieve one thread (carries `agent`
snapshot, `status`, `parent_thread_id`, `stats`, `usage`) |
| `POST` | `/v1/sessions/{session_id}/threads/{thread_id}/archive` | ArchiveThread | Archive a thread |
| `GET` | `/v1/sessions/{session_id}/threads/{thread_id}/events` | ListThreadEvents | List past events for
one thread (paginated) |
| `GET` | `/v1/sessions/{session_id}/threads/{thread_id}/stream` | StreamThreadEvents | Stream one thread via
SSE (SDK: `threads.events.stream`) |

## Session Resources

| Method   | Path                                                      | Operation        | Description
|
| -------- | --------------------------------------------------------- | ---------------- |
--------------------------------------- |
| `GET` | `/v1/sessions/{session_id}/resources` | ListResources | List resources attached to session |
| `POST` | `/v1/sessions/{session_id}/resources` | AddResource | Attach `file` or `github_repository`
resource (SDK method: `add`, not `create`). `memory_store` resources attach at session-create time only. |
| `GET` | `/v1/sessions/{session_id}/resources/{resource_id}` | GetResource | Get a single resource |
| `POST` | `/v1/sessions/{session_id}/resources/{resource_id}` | UpdateResource | Update resource |
| `DELETE` | `/v1/sessions/{session_id}/resources/{resource_id}` | DeleteResource | Remove resource from
session |

## Environments

| Method   | Path                                                                  | Operation            |
Description                          |
| -------- | --------------------------------------------------------------------- | -------------------- |
---------------------------------- |
| `POST`   | `/v1/environments`                                       | CreateEnvironment    | Create
environment                  |
| `GET`    | `/v1/environments`                                       | ListEnvironments     | List
environments                   |
| `GET`    | `/v1/environments/{environment_id}`                      | GetEnvironment       | Get environment
details             |
| `POST`   | `/v1/environments/{environment_id}`                      | UpdateEnvironment    | Update
environment                  |
| `DELETE` | `/v1/environments/{environment_id}`                      | DeleteEnvironment    | Delete
environment. Returns 204. |
| `POST`   | `/v1/environments/{environment_id}/archive`              | ArchiveEnvironment   | Archive
environment. Makes it **read-only**; existing sessions continue, new sessions cannot reference it. No
```

```
unarchive -- this is the terminal state. |
| `GET`    | `/v1/environments/{environment_id}/work/stats`         | WorkQueueStats       | Self-hosted
work-queue depth/pending/workers. `x-api-key` auth. See `shared/managed-agents-self-hosted-sandboxes.md`. |
| `POST`   | `/v1/environments/{environment_id}/work/{work_id}/stop` | StopWork            | Self-hosted:
stop a claimed work item. `x-api-key` auth. |

For `type: "self_hosted"`, `config` is the bare `{"type": "self_hosted"}` -- `networking` and `packages` do
not apply.

## Deployments

Scheduled deployments (`depl_` IDs) run an agent on a recurring cron schedule -- each firing creates a
session. See `shared/managed-agents-scheduled-deployments.md` for the conceptual guide (cron/DST semantics,
failure behavior, lifecycle).

| Method   | Path                                              | Operation        | Description
|
| -------- | ------------------------------------------------- | ---------------- |
--------------------------------------- |
| `POST`   | `/v1/deployments`                                 | CreateDeployment | Create a scheduled
deployment            |
| `POST`   | `/v1/deployments/{deployment_id}`                 | UpdateDeployment | Update deployment
configuration (see `shared/managed-agents-scheduled-deployments.md`) |
| `POST`   | `/v1/deployments/{deployment_id}/pause`           | PauseDeployment  | Suppress scheduled
triggers (reversible; manual runs still allowed) |
| `POST`   | `/v1/deployments/{deployment_id}/unpause`         | UnpauseDeployment | Resume from the next
occurrence (no backfill) |
| `POST`   | `/v1/deployments/{deployment_id}/archive`         | ArchiveDeployment | **Terminal** -- schedule
stops, deployment becomes immutable |
| `POST`   | `/v1/deployments/{deployment_id}/run`             | RunDeployment    | Trigger a manual run
immediately (`trigger_context.type: "manual"`); works while paused |

## Deployment Runs

Each trigger attempt (scheduled or manual) writes a `deployment_run` record (`drun_` IDs) carrying either the
created `session_id` or an `error.type` (`environment_archived`, `agent_archived`, `vault_not_found`,
`session_rate_limited`, `service_unavailable`).

| Method   | Path                                              | Operation        | Description
|
| -------- | ------------------------------------------------- | ---------------- |
--------------------------------------- |
| `GET`    | `/v1/deployment_runs?deployment_id=...`           | ListDeploymentRuns | List runs for a
deployment (paginated; filter failures with `has_error=true`) |
| `GET`    | `/v1/deployment_runs/{deployment_run_id}`         | GetDeploymentRun   | Retrieve a single run by
ID (a `deployment_run.*` webhook event carries this as `data.id`) |

## Vaults

Vaults store credentials that Anthropic manages on your behalf -- MCP credentials (OAuth with auto-refresh,
or static bearer tokens) and `environment_variable` credentials substituted into outbound requests at egress.
Attach to sessions via `vault_ids`. See `managed-agents-tools.md` ?Vaults for the conceptual guide and
credential shapes.

| Method   | Path                                              | Operation        | Description
|
| -------- | ------------------------------------------------- | ---------------- |
--------------------------------------- |
| `POST`   | `/v1/vaults`                                      | CreateVault      | Create a vault
|
| `GET`    | `/v1/vaults`                                      | ListVaults       | List vaults
|
| `GET`    | `/v1/vaults/{vault_id}`                           | GetVault         | Get vault details
|
| `POST`   | `/v1/vaults/{vault_id}`                           | UpdateVault      | Update vault
|
| `DELETE` | `/v1/vaults/{vault_id}`                           | DeleteVault      | Delete vault
|
| `POST`   | `/v1/vaults/{vault_id}/archive`                   | ArchiveVault     | Archive vault
|
```

```
## Credentials

Credentials are individual secrets stored inside a vault.

| Method   | Path                                                                 | Operation          |
Description                  |
| -------- | -------------------------------------------------------------------- | ------------------ |
---------------------------- |
| `POST`   | `/v1/vaults/{vault_id}/credentials`                                  | CreateCredential   | Create
a credential          |
| `GET`    | `/v1/vaults/{vault_id}/credentials`                                  | ListCredentials    | List
credentials in vault    |
| `GET`    | `/v1/vaults/{vault_id}/credentials/{credential_id}`                  | GetCredential      | Get
credential metadata      |
| `POST`   | `/v1/vaults/{vault_id}/credentials/{credential_id}`                  | UpdateCredential   | Update
credential            |
| `DELETE` | `/v1/vaults/{vault_id}/credentials/{credential_id}`                  | DeleteCredential   | Delete
credential            |
| `POST`   | `/v1/vaults/{vault_id}/credentials/{credential_id}/archive`          | ArchiveCredential  | Archive
credential           |
| `POST`   | `/v1/vaults/{vault_id}/credentials/{credential_id}/mcp_oauth_validate` | McpOauthValidate |
Validate an MCP OAuth credential |

## Memory Stores

Workspace-scoped persistent memory that survives across sessions. Attach to a session via a `{"type":
"memory_store", "memory_store_id": ...}` entry in `resources[]` (session-create time only). See
`shared/managed-agents-memory.md` for the conceptual guide, the FUSE-mount agent interface, preconditions,
and versioning.

| Method   | Path                                                | Operation          | Description
|
| -------- | --------------------------------------------------- | ------------------ |
---------------------------------------- |
| `POST`   | `/v1/memory_stores`                                 | CreateMemoryStore  | Create a store (`name`,
`description`, `metadata`) |
| `GET`    | `/v1/memory_stores`                                 | ListMemoryStores   | List stores
(`include_archived`, `created_at_{gte,lte}`) |
| `GET`    | `/v1/memory_stores/{memory_store_id}`               | GetMemoryStore     | Get store details
|
| `POST`   | `/v1/memory_stores/{memory_store_id}`               | UpdateMemoryStore  | Update store
|
| `DELETE` | `/v1/memory_stores/{memory_store_id}`               | DeleteMemoryStore  | Delete store
|
| `POST`   | `/v1/memory_stores/{memory_store_id}/archive`       | ArchiveMemoryStore | Archive store. Makes it
**read-only**; existing sessions continue, new sessions cannot reference it. No unarchive. |

## Memories

Individual text documents inside a store (<= 100KB each). `create` creates at a `path` and returns `409`
(`memory_path_conflict_error`, with `conflicting_memory_id`) if the path is occupied; `update` mutates by
`mem_...` ID (rename and/or content). Only `update` accepts a `precondition` (`{"type": "content_sha256",
"content_sha256": ...}`) -- on mismatch returns `409` (`memory_precondition_failed_error`). List endpoints
accept `view: "basic"|"full"` (controls whether `content` is populated; `retrieve` defaults to `full`).

| Method   | Path                                                                 | Operation      | Description
|
| -------- | -------------------------------------------------------------------- | -------------- |
---------------------------------------- |
| `GET`    | `/v1/memory_stores/{memory_store_id}/memories`                       | ListMemories   | Returns
`Memory \| MemoryPrefix`; filter by `path_prefix`, `depth` |
| `POST`   | `/v1/memory_stores/{memory_store_id}/memories`                       | CreateMemory   | Create at
`path` (SDK: `memories.create`); `409 memory_path_conflict_error` if occupied |
| `GET`    | `/v1/memory_stores/{memory_store_id}/memories/{memory_id}`           | GetMemory      | Read one
memory (defaults to `view="full"`) |
| `PATCH`  | `/v1/memory_stores/{memory_store_id}/memories/{memory_id}`           | UpdateMemory   | Change
`content`, `path`, or both by ID; optional `precondition` |
| `DELETE` | `/v1/memory_stores/{memory_store_id}/memories/{memory_id}`           | DeleteMemory   | Delete
(optional `expected_content_sha256`) |
```

```
## Memory Versions

Immutable per-mutation snapshots (`memver_...`) -- the audit and rollback surface. `operation` ? `created` /
`modified` / `deleted`.

| Method   | Path                                                                                  | Operation
| Description                              |
| -------- | ------------------------------------------------------------------------------------- |
-------------------- | ---------------------------------------- |
| `GET`    | `/v1/memory_stores/{memory_store_id}/memory_versions`                                 |
ListMemoryVersions    | Newest-first; filter by `memory_id`, `operation`, `session_id`, `api_key_id`,
`created_at_{gte,lte}` |
| `GET`    | `/v1/memory_stores/{memory_store_id}/memory_versions/{version_id}`            | GetMemoryVersion
| List fields + full `content`             |
| `POST`   | `/v1/memory_stores/{memory_store_id}/memory_versions/{version_id}/redact`     |
RedactMemoryVersion   | Clear `content`/`content_sha256`/`content_size_bytes`/`path`; preserve actor +
timestamps |

## Files

| Method   | Path                                                | Operation        | Description
|
| -------- | --------------------------------------------------- | ---------------- |
---------------------------------------- |
| `POST`   | `/v1/files`                                | UploadFile       | Upload a file
|
| `GET`    | `/v1/files`                                | ListFiles        | List files
|
| `GET`    | `/v1/files/{file_id}`                      | GetFile          | Get file metadata (SDK method:
`retrieve_metadata`) |
| `GET`    | `/v1/files/{file_id}/content`              | DownloadFile     | Download file content
|
| `DELETE` | `/v1/files/{file_id}`                      | DeleteFile       | Delete a file
|

## Skills

| Method   | Path                                                                  | Operation          |
Description                  |
| -------- | --------------------------------------------------------------------- | ------------------ |
---------------------------- |
| `POST`   | `/v1/skills`                                          | CreateSkill        | Create a skill
|
| `GET`    | `/v1/skills`                                          | ListSkills         | List skills
|
| `GET`    | `/v1/skills/{skill_id}`                               | GetSkill           | Get skill details
|
| `DELETE` | `/v1/skills/{skill_id}`                               | DeleteSkill        | Delete a skill
|
| `POST`   | `/v1/skills/{skill_id}/versions`                      | CreateVersion      | Create skill
version         |
| `GET`    | `/v1/skills/{skill_id}/versions`                      | ListVersions       | List skill versions
|
| `GET`    | `/v1/skills/{skill_id}/versions/{version}`            | GetVersion         | Get skill version
|
| `DELETE` | `/v1/skills/{skill_id}/versions/{version}`            | DeleteVersion      | Delete skill
version         |

---

## Request/Response Schema Quick Reference

### CreateAgent Request Body

**Always start here.** `model`, `system`, `tools`, `mcp_servers`, `skills` are top-level fields on this
object -- they do NOT go on the session.

```json
{
```
```

```
  "name": "string (required, 1-256 chars)",
  "model": "claude-opus-5 (required -- bare string, or {id, speed?, effort?, inference_geo?} object)",
  "description": "string (optional, up to 2048 chars)",
  "system": "string (optional, up to 100,000 chars)",
  "tools": [
    { "type": "agent_toolset_20260401" }
  ],
  "skills": [
    { "type": "anthropic", "skill_id": "xlsx" },
    { "type": "custom", "skill_id": "skill_abc123", "version": "1" }
  ],
  "mcp_servers": [
    {
      "type": "url",
      "name": "github",
      "url": "https://api.githubcopilot.com/mcp/"
    }
  ],
  "multiagent": {
    "type": "coordinator",
    "agents": [
      "agent_abc123",
      { "type": "agent", "id": "agent_def456", "version": 4 },
      { "type": "self" }
    ]
  },
  "metadata": {
    "key": "value (max 16 pairs, keys <=64 chars, values <=512 chars)"
  }
}
```

> Limits: `tools` max 128, `skills` max 20, `mcp_servers` max 20 (unique names). `multiagent.agents` 1-20 entries (string ID | `{type:"agent",id,version?}` | `{type:"self"}` | `{type:"advisor",model}`, at most one advisor) -- see `shared/managed-agents-multiagent.md`.

CreateSession Request Body

```json
{
  "agent": "agent_abc123 (required -- string shorthand for latest version, or {type: \"agent\", id, version} object)",
  "environment_id": "env_abc123 (required)",
  "title": "string (optional)",
  "resources": [
    {
      "type": "github_repository",
      "url": "https://github.com/owner/repo (required)",
      "authorization_token": "ghp_... (required)",
      "mount_path": "/workspace/repo (optional -- defaults to /workspace/<repo-name>)",
      "checkout": { "type": "branch", "name": "main" }
    }
  ],
  "initial_events": [
    { "type": "user.message", "content": [{ "type": "text", "text": "Review the auth module." }] }
  ],
  "vault_ids": ["vlt_abc123 (optional -- vault credentials: MCP auth + environment variables)"],
  "budget": {
    "type": "limit",
    "max_list_cost": { "amount": "2500", "currency": "USD" }
  },
  "metadata": {
    "key": "value"
  }
}
```

> The `agent` field accepts a string ID, `{type: "agent", id, version}`, or `{type: "agent_with_overrides", id, version?, ...}` for session-local overrides of `model`/`system`/`tools`/`mcp_servers`/`skills`. Outside the overrides form, those fields live on the agent, not here. An `effort` inside a `model` override is

````
ignored -- set it on the agent. An `inference_geo` inside a `model` override **is** applied (omitting it
clears the agent's pin for this session).
>
> **`budget`** (optional, create-only) is a hard dollar cap on the session's list-priced spend; `amount` is
an integer string in minor units (cents -- `"2500"` = $25.00), `USD` only. It can be changed or removed later
via session update, never added. See `shared/managed-agents-core.md` -> Session budgets.
>
> **`initial_events`** (optional, max 50) sends events at creation and starts the agent loop in the same
call. Only `user.message` and `user.define_outcome` are accepted -- no `system.message`, and none of the
tool-result kinds. Validation is all-or-nothing. See `shared/managed-agents-core.md` -> Seeding a session
with `initial_events`.
>
> **`checkout`** accepts `{type: "branch", name: "..."}` or `{type: "commit", sha: "..."}`. Omit for the
repo's default branch.

### CreateEnvironment Request Body

```json
{
  "name": "string (required)",
  "description": "string (optional)",
  "config": {
    "type": "cloud | self_hosted",
    "networking": {
      "type": "unrestricted | limited (union -- see SDK types)"
    },
    "packages": { }
  },
  "metadata": { "key": "value" }
}
```

### CreateDeployment Request Body

```json
{
  "name": "Weekly compliance scan",
  "agent": "agent_abc123 (required -- same shapes as CreateSession)",
  "environment_id": "env_abc123 (required)",
  "initial_events": [
    { "type": "user.message", "content": [{ "type": "text", "text": "Run the weekly compliance scan." }] }
  ],
  "schedule": {
    "type": "cron",
    "expression": "0 20 * * 5",
    "timezone": "America/New_York"
  }
}
```

> Optional session config (`resources`, `vault_ids`, etc.) is supported the same way as on CreateSession,
including `budget` -- copied onto each fired session; unlike a session's, it can be added where none exists
and re-added after clearing (see `shared/managed-agents-scheduled-deployments.md` ? Deployment budgets).
Response includes `status`, `paused_reason`, and `schedule.upcoming_runs_at` (next fire times). See
`shared/managed-agents-scheduled-deployments.md`.

### SendEvents Request Body

```json
{
  "events": [
    {
      "type": "user.message",
      "content": [
        {
          "type": "text",
          "text": "Hello"
        }
      ]
    }
````
````

```
  ]
}
```

> `system.message` events (append system-level context for this turn and later ones) use the same envelope with `type: "system.message"` -- supported on Claude Opus 5, Claude Opus 4.8, Claude Sonnet 5, Claude Fable 5, and Claude Mythos 5, checked against the agent's *primary* model only; see `shared/managed-agents-events.md` ? Adding system context mid-session.

Define Outcome Event

```json
{
  "type": "user.define_outcome",
  "description": "Build a DCF model for Costco in .xlsx",
  "rubric": { "type": "file", "file_id": "file_01..." },
  "max_iterations": 5
}
```

> `rubric` is required: `{type: "text", content}` or `{type: "file", file_id}`. `max_iterations` default 3, max 20. Echoed back with `outcome_id` + `processed_at`. See `shared/managed-agents-outcomes.md`.

Tool Result Event

```json
{
  "type": "user.custom_tool_result",
  "custom_tool_use_id": "sevt_abc123",
  "content": [{ "type": "text", "text": "Result data" }],
  "is_error": false
}
```

Error Handling

Managed Agents endpoints use the standard Anthropic API error format. Errors are returned with an HTTP status code and a JSON body containing `type`, `error`, and `request_id`:

```json
{
  "type": "error",
  "error": {
    "type": "invalid_request_error",
    "message": "Description of what went wrong"
  },
  "request_id": "req_011CRv1W3XQ8XpFikNYG7RnE"
}
```

Include the `request_id` when reporting issues to Anthropic -- it lets us trace the request end-to-end. The inner `error.type` is one of the following:

Status	Error type	Description
400	`invalid_request_error`	The request was malformed or missing required parameters
401	`authentication_error`	Invalid or missing API key
403	`permission_error`	The API key doesn't have permission for this operation
404	`not_found_error`	The requested resource doesn't exist
409	`invalid_request_error`	The request conflicts with the resource's current state (e.g., sending to an archived session)
413	`request_too_large`	The request body exceeds the maximum allowed size
429	`rate_limit_error`	Too many requests -- check rate limit headers for retry timing
500	`api_error`	An internal server error occurred
529	`overloaded_error`	The service is temporarily overloaded -- retry with backoff

Note that `409 Conflict` carries `error.type: "invalid_request_error"` (there is no separate `conflict_error` type); inspect both the HTTP status and the `message` to distinguish conflicts from other invalid requests.

```
---

## Pagination

Most Managed Agents list endpoints use the `page` / `next_page` cursor scheme:

| Field | Where | Notes |
|---|---|---|
| `limit` | query | Max items per page |
| `page` | query | Opaque cursor from a previous response -- pass a `next_page` or `prev_page` value here |
| `order` | query | `asc` / `desc` on endpoints that support sorting. A cursor encodes the `order` of the request that produced it -- reusing it with a different `order` returns 400. Other params (filters, `limit`) can change between paginated requests. |
| `next_page` | response | Cursor for the next page; `null` when there are no more results |
| `prev_page` | response | Cursor for the previous page on endpoints that support backward pagination -- currently **only `GET /v1/sessions`**. `null` on the first page. On endpoints that don't support it, the field is **absent** (not `null`). |

Every SDK exposes an auto-paginating iterator that follows `next_page`. In Python and TypeScript, iterate the list result directly; the other SDKs expose the iterator via a separate method (iterating the plain list result returns one page). SDK auto-pagination is **forward-only** -- to go back a page, read `prev_page` from the response and pass it back as the `page` parameter yourself.

> ?? Some endpoints use a **different** cursor scheme: Message Batches, Files, Models, and several Admin API endpoints take `after_id`/`before_id` and return `has_more`/`first_id`/`last_id` instead of `page`/`next_page`. Some `page`-scheme endpoints (e.g. `GET /v1/skills`) also return a `has_more` boolean alongside `next_page`. Check the endpoint's reference page for its exact pagination fields.

---

## Rate Limits

Managed Agents endpoints have per-organization request-per-minute (RPM) limits, separate from your [Messages API token limits](https://platform.claude.com/docs/en/api/rate-limits). Model inference inside a session still draws from your organization's standard ITPM/OTPM limits.

| Endpoint group | Scope | RPM | Max concurrent |
|---|---|---|---|
| Create operations (Agents, Sessions, Vaults) | organization | 300 | -- |
| All other operations (Agents, Sessions, Vaults) | organization | 600 | -- |
| All operations (Environments) | organization | 60 | 5 |

Files and Skills endpoints use the standard tier-based [rate limits](https://platform.claude.com/docs/en/api/rate-limits).

When a limit is exceeded the API returns `429` with a `rate_limit_error` (see [Error Handling](#error-handling) for the response envelope) and a `retry-after` header indicating how many seconds to wait before retrying. The Anthropic SDK reads this header and retries automatically.
</doc>

<doc path="shared/managed-agents-client-patterns.md">
# Managed Agents -- Common Client Patterns

Patterns you'll write on the client side when driving a Managed Agent session, grounded in working SDK examples.

Code samples are TypeScript -- other languages follow the same shape; see `{lang}/managed-agents/README.md` (cURL and C#: `curl/managed-agents.md`) for equivalents.

---

## 1. Lossless stream reconnect

**Problem:** SSE has no replay. If the connection drops mid-session, a naive reconnect re-opens the stream from "now" and you silently miss every event emitted in between.

**Solution:** on reconnect, fetch the full event history via `events.list()` *before* consuming the live stream, and dedupe on event ID as the live stream catches up.
```

```ts
const seenEventIds = new Set<string>()
const stream = await client.beta.sessions.events.stream(session.id)

// Stream is now open and buffering server-side. Read history first.
for await (const event of client.beta.sessions.events.list(session.id)) {
  seenEventIds.add(event.id)
  handle(event)
}

// Tail the live stream. Dedupe only gates handle() -- terminal checks must run
// even for already-seen events, or a terminal event that was in the history
// response gets skipped by `continue` and the loop never exits.
for await (const event of stream) {
  if (!seenEventIds.has(event.id)) {
    seenEventIds.add(event.id)
    handle(event)
  }
  if (event.type === 'session.status_terminated') break
  if (event.type === 'session.status_idle' && event.stop_reason.type !== 'requires_action') break
}
```

---

2. `processed_at` -- queued vs processed

Every event on the stream carries `processed_at` (ISO 8601), set when the event finishes processing. For client-sent events (`user.message`, `user.interrupt`, `user.tool_confirmation`) it's `null` while the event is queued behind earlier ones, and populated once the agent processes it -- so the same event appears on the stream twice, once with `null` and once with a timestamp. (Exception: a `user.interrupt` sent while the session is paused at its budget is accepted and ignored -- it never appears at all; see `shared/managed-agents-events.md` ? Reaching a session budget.)

Three event types skip the queued phase: `user.define_outcome`, `user.custom_tool_result`, and `user.tool_result` are processed on receipt and echoed back with `processed_at` already populated. A pending -> acknowledged UI that assumes "first sighting is always `null`" will never clear for these -- treat a populated `processed_at` on first sighting as immediately acknowledged.

```ts
for await (const event of stream) {
  if (event.type === 'user.message') {
    if (event.processed_at == null) onQueued(event.id)
    else onProcessed(event.id, event.processed_at)
  }
}
```

Use this to drive pending -> acknowledged UI state for anything you send. How you map a locally-rendered optimistic message to the server-assigned `event.id` is application-specific (typically via the return value of `events.send()` or FIFO ordering).

---

3. Interrupt a running session

Send `user.interrupt` as a normal event. The session keeps running until it reaches a safe boundary, then goes idle.

```ts
await client.beta.sessions.events.send(session.id, {
  events: [{ type: 'user.interrupt' }],
})

// Drain until the session is truly done -- see Pattern 5 for the full gate.
for await (const event of stream) {
  if (event.type === 'session.status_terminated') break
  if (
    event.type === 'session.status_idle' &&
    event.stop_reason.type !== 'requires_action'
```

```
  ) break
}
```

Reference: `interrupt.ts` -- sends the interrupt the moment it sees `span.model_request_start`, drains to idle, then verifies via `sessions.retrieve()`.

---

4. `tool_confirmation` round-trip

When the agent has `permission_policy: { type: 'always_ask' }`, any call to that tool fires an `agent.tool_use` event with `evaluated_permission === 'ask'` and the session goes idle waiting for a decision. Respond with `user.tool_confirmation`.

```ts
for await (const event of stream) {
  if (event.type === 'agent.tool_use' && event.evaluated_permission === 'ask') {
    await client.beta.sessions.events.send(session.id, {
      events: [{
        type: 'user.tool_confirmation',
        tool_use_id: event.id,         // not a toolu_ id -- use event.id
        result: 'allow',               // or 'deny'
        // deny_message: '...',        // optional, only with result: 'deny'
      }],
    })
  }
}
```

Key points:
- `tool_use_id` is `event.id` (typically `sevt_...`), **not** a `toolu_...` ID.
- `result` is `'allow' | 'deny'`. Use `deny_message` to tell the model *why* you denied -- it gets surfaced back to the agent.
- Multiple pending tools: respond once per `agent.tool_use` event with `evaluated_permission === 'ask'`.

Reference: `tool-permissions.ts`.

---

5. Correct idle-break gate

Do not break on `session.status_idle` alone. The session goes idle transiently -- e.g. between parallel tool executions, while waiting for a `user.tool_confirmation`, or while awaiting a `user.custom_tool_result`. Break when idle with a non-`requires_action` `stop_reason` (terminal, or `budget_reached` -- resumable only by a budget update, so break unless you intend to change or remove the budget), or on `session.status_terminated`.

```ts
for await (const event of stream) {
  handle(event)
  if (event.type === 'session.status_terminated') break
  if (event.type === 'session.status_idle') {
    if (event.stop_reason.type === 'requires_action') continue // waiting on you -- handle it
    break // end_turn, retries_exhausted, or budget_reached -- see list below
  }
}
```

`stop_reason.type` values on `session.status_idle`:
- `requires_action` -- agent is waiting on a client-side event (tool confirmation, custom tool result). Handle it, don't break.
- `retries_exhausted` -- terminal failure. Break, then check `sessions.retrieve()` for the error state.
- `end_turn` -- normal completion.
- `budget_reached` -- the session hit its spend cap and paused. Not terminal and not resumable by any event: change (typically raise) or remove the session's `budget` to resume, or treat it as done. A `session.usage` event with the final cost immediately precedes this idle. See `shared/managed-agents-core.md` ? Session budgets.

```
## 6. Post-idle status-write race

The SSE stream emits `session.status_idle` slightly before the session's queryable status reflects it.
Clients that break on idle and immediately call `sessions.delete()` or `sessions.archive()` will
intermittently 400 with "cannot delete/archive while running."

Poll before cleanup:

```ts
let s
for (let i = 0; i < 10; i++) {
  s = await client.beta.sessions.retrieve(session.id)
  if (s.status !== 'running') break
  await new Promise(r => setTimeout(r, 200))
}
if (s?.status !== 'running') {
  await client.beta.sessions.archive(session.id)
} // else: still running after 2s -- don't archive, let it settle or escalate
```

---

7. Stream-first, then send

Always open the stream **before** sending the kickoff event. Otherwise the agent may process the event and
emit the first events before your consumer is attached, and you'll miss them.

```ts
const stream = await client.beta.sessions.events.stream(session.id)
await client.beta.sessions.events.send(session.id, {
  events: [{ type: 'user.message', content: [{ type: 'text', text: 'Hello' }] }],
})
for await (const event of stream) { /* ... */ }
```

The `Promise.all([stream, send])` shape works too, but stream-first is simpler and has the same effect -- the
stream starts buffering the moment it's opened.

---

8. File-mount gotchas

The mounted resource has a different `file_id` than the file you uploaded. Session creation makes a
session-scoped copy.

```ts
const uploaded = await client.beta.files.upload({ file, purpose: 'agent_resource' })
// uploaded.id         -> the original file
const session = await client.beta.sessions.create({
  /* ... */
  resources: [{ type: 'file', file_id: uploaded.id, mount_path: '/workspace/data.csv' }],
})
// session.resources[0].file_id !== uploaded.id  <- different IDs
```

Delete the original via `files.delete(uploaded.id)`; the session-scoped copy is garbage-collected with the
session. `mount_path` must be absolute -- see `shared/managed-agents-environments.md`.

---

9. Secrets for non-MCP APIs and CLIs -- keep them host-side via custom tools

Problem: you want the agent to call a third-party API or run a CLI that needs a secret (API key, token,
service-account credential), but you can't or don't want to hand the secret to a vault.

First check: for cloud environments, the first-class answer is now a vault `environment_variable`
credential -- the agent's shell sees an opaque placeholder and the real secret is substituted at egress. See
`shared/managed-agents-tools.md` -> Vaults. Use this pattern instead when that doesn't fit: **self-hosted
sandboxes** (env-var credentials not yet supported there), clients that reject the placeholder via local
```

format validation, secrets that must never leave your infrastructure, or calls that need host-side binaries.

Solution: move the authenticated call to your side. Declare a custom tool on the agent; when the agent emits `agent.custom_tool_use`, your orchestrator (the process reading the SSE stream) executes the call with its own credentials and responds with `user.custom_tool_result`. The container never sees the key.

```ts
// Agent template: declare the tool, no credentials
tools: [{ type: 'custom', name: 'linear_graphql', input_schema: { /* query, vars */ } }]

// Orchestrator: handle the call with host-side creds
for await (const event of stream) {
  if (event.type === 'agent.custom_tool_use' && event.name === 'linear_graphql') {
    const result = await linear.request(event.input.query, event.input.vars) // host's key
    await client.beta.sessions.events.send(session.id, {
      events: [{
        type: 'user.custom_tool_result',
        custom_tool_use_id: event.id,
        content: [{ type: 'text', text: JSON.stringify(result) }],
      }],
    })
  }
}
```

Same shape works for `gh` CLI, local eval scripts, or anything else that needs host-side auth or binaries.

Security note: this does not expose a public endpoint. `agent.custom_tool_use` arrives on the SSE stream your orchestrator already holds open with your Anthropic API key, and `user.custom_tool_result` goes back via `events.send()` under the same key. Your orchestrator is a client, not a server -- nothing unauthenticated is listening.

Do not embed API keys in the system prompt or user messages as a workaround. Prompts and messages are stored in the session's event history, returned by `events.list()`, and included in compaction summaries -- a secret placed there is durably persisted and readable via the API for the life of the session.
</doc>

<doc path="shared/managed-agents-core.md">
Managed Agents -- Core Concepts

Architecture

Managed Agents is built around four core concepts:

Concept	Endpoint	What it is
Agent	`/v1/agents`	A persisted, versioned object defining the agent's capabilities and persona: model, system prompt, tools, MCP servers, skills. **Must be created before starting a session.** See the Agents section below.
Session	`/v1/sessions`	A stateful interaction with an agent. References a pre-created agent by ID + an environment + initial instructions. Produces an event stream.
Environment	`/v1/environments`	A template defining the configuration for container provisioning.
Container	N/A	An isolated compute instance where the agent's **tools** execute (bash, file ops, code). The agent loop does not run here -- it runs on Anthropic's orchestration layer and acts on the container via tool calls.

```
                      +--------------------------------------+
                      |  Anthropic orchestration layer       |
Agent (config) -------?|  (agent loop: Claude + tool calls)  |
                      +--------------+-----------------------+
                                     | tool calls
                                     ?
Environment (template) --? Container (tool execution workspace)
                                |
                        Session -+
                                +-- Resources (files, repos, memory stores -- attached at startup)
                                +-- Vault IDs (MCP credential references)
                                +-- Conversation (event stream in/out)
```

````
> **Agent creation is a prerequisite.** Sessions reference a pre-created agent by ID --
`model`/`system`/`tools` live on the agent object, never on the session. Every flow starts with `POST
/v1/agents`.

---

## Session Lifecycle

```
rescheduling -> running <-> idle -> terminated
```

| Status         | Description                                                                 |
| -------------- | --------------------------------------------------------------------------- |
| `idle` | Agent has finished the current task, and is awaiting input. It's either waiting for input to
continue working via a `user.message`, blocked awaiting a `user.custom_tool_result` or
`user.tool_confirmation`, or paused because the session budget cap was reached. The `stop_reason` attached
contains more information about why the Agent has stopped working. |
| `running` | Session has starting running, and the Agent is actively doing work. |
| `rescheduling` | Session is (re)scheduling after a retryable error has occurred, ready to be picked up by
the orchestration system. |
| `terminated` | Session has ended and is in an irreversible, unusable state -- **either on completion or
because of an unrecoverable error**. Terminated does not by itself mean failure; fetch the session to tell
the two apart. |

- Events can be sent when the session is `running` or `idle`. Messages are queued and processed in order.
Exception: a session paused at its budget (`stop_reason: budget_reached`) accepts only **settle events** --
events that resolve work already in progress (`user.tool_confirmation`, `user.tool_result`,
`user.custom_tool_result`, `user.interrupt`) rather than starting new work -- see ? Session budgets.
- The agent transitions `idle -> running` when it receives a new event, then back to `idle` when done.
- Errors surface as `session.error` events in the stream, not as a status value.

Every session has a live trace view in the Anthropic Console at
`https://platform.claude.com/workspaces/{workspace}/sessions/{session_id}`. Print this URL immediately after
creating a session so the user can watch tool calls and messages stream in real time. **`{workspace}` is the
workspace the API key belongs to** -- use `default` only when that's the org's Default workspace. The session
response does **not** include a workspace field and the Console has no workspace-agnostic session route, so
for non-default workspaces substitute the workspace's ID (visible in the Console URL bar, or expose it as a
config value alongside the API key). A `default` link to a session that lives in another workspace lands on a
**"Session not found"** page -- the **Search workspaces** button there will locate it, but it is not an
automatic redirect.

### Built-in session features

- **Context compaction** -- if you approach max context, the API automatically condenses session history to
keep the interaction going
- **Prompt caching** -- historical repeated tokens are cached, reducing processing time and cost
- **Extended thinking** -- on by default; `agent.thinking` events signal thinking progress and carry no
thinking content

### Session operations

| Operation | Notes |
|---|---|
| List / fetch | Paginated list or single resource by ID |
| Update | `title`, `metadata`, and the session-local `agent.tools`/`agent.mcp_servers` can be overridden
(see ? Updating the agent configuration mid-session). `budget` can only be changed or removed (see ? Session
budgets). `vault_ids` is create-only -- update requests setting it are rejected. |
| Archive | Session becomes **read-only**. Not reversible. |
| Delete | Permanently deletes session, event history, container, and checkpoints. |

These are ops/inspection calls -- typically made from a terminal, not application code. From the shell (see
`shared/anthropic-cli.md`):

```sh
ant beta:sessions list --transform '{id,title,status,created_at}' --format jsonl
ant beta:sessions retrieve --session-id "$SID"
ant beta:sessions:events stream --session-id "$SID"   # watch events live
ant beta:sessions archive  --session-id "$SID"
````
````

```
ant beta:sessions delete   --session-id "$SID"
```

Sessions

A session is a running agent instance inside an environment.

Session Object

Key fields returned by the API:

Field	Type	Description
`type`	string	Always `"session"`
`id`	string	Unique session ID
`title`	string	Human-readable title
`status`	string	`idle`, `running`, `rescheduling`, `terminated`
`created_at`	string	ISO 8601 timestamp
`updated_at`	string	ISO 8601 timestamp
`archived_at`	string	ISO 8601 timestamp (nullable)
`environment_id`	string	Environment ID
`agent`	object	Agent configuration
`resources`	array	Attached files, repos, and memory stores
`metadata`	object	User-provided key-value pairs (max 8 keys)
`usage`	object	Cumulative usage: token counts, `server_tool_use` (web search/fetch request counts), `list_cost` (consumption priced at public list rates, as `{amount, currency}` with the amount an integer string in minor units -- cents), and `active_seconds` (time with >=1 thread running; concurrent-thread overlap counted once -- unlike `stats.active_seconds`, which sums per-thread time)
`budget`	object	The session's spend cap, when one was set at creation -- see ? Session budgets
`stats`	object	Timing statistics -- `stats.active_seconds` sums per-thread time, unlike `usage.active_seconds`

Creating a session

A session is meaningless without an agent. Sessions reference a pre-created agent by ID. Create the agent first via `agents.create()`, then reference it:

```ts
// 1. Create the agent (reusable, versioned)
const agent = await client.beta.agents.create(
  {
    name: "Coding Assistant",
    model: "claude-opus-5",
    system: "You are a helpful coding agent.",
    tools: [{ type: "agent_toolset_20260401"}],
  },
);

// 2. Start a session that references it
const session = await client.beta.sessions.create(
  {
    agent: agent.id,  // string shorthand -> latest version. Or: { type: "agent", id: agent.id, version: agent.version }
    environment_id: environmentId,
    title: "Hello World Session",
  },
);
```

> ? **Watch it live in Console.** While developing, print a link so you can click through to the session UI instead of parsing the event stream: `https://platform.claude.com/workspaces/{workspace}/sessions/{session.id}`. Use `default` for `{workspace}` only when the API key belongs to the org's Default workspace; otherwise substitute the workspace's ID (the session response does not carry it -- read it from the Console URL bar or make it a config value). Include this `print`/`console.log` in code you generate for users who are iterating locally.

Session creation parameters:

```
| Field           | Type     | Required | Description                                   |
| --------------- | -------- | -------- | --------------------------------------------- |
| `agent`         | string or object | **Yes** | Three forms: string shorthand `"agent_abc123"` (latest
version); pinned `{type: "agent", id, version}`; or `{type: "agent_with_overrides", id, version?, ...}` to
override `model`/`system`/`tools`/`mcp_servers`/`skills` for this session only -- see ? Override agent
configuration for a session |
| `environment_id`| string   | **Yes**  | Environment ID                                |
| `title`         | string   | No       | Human-readable name (appears in logs/dashboards) |
| `resources`     | array    | No       | Files, GitHub repos, or memory stores, attached to the container at
startup. Memory stores are session-create-only (not addable via `resources.add()`). |
| `initial_events`| array    | No       | Events to send at creation, processed in order -- collapses create
+ first send into one call. See ? Seeding a session with `initial_events` below. |
| `vault_ids`     | array    | No       | Vault IDs (`vlt_*`) -- MCP credentials with auto-refresh +
`environment_variable` secrets substituted at egress. See `shared/managed-agents-tools.md` -> Vaults. |
| `budget`        | object   | No       | Hard dollar cap on the session's spend: `{type: "limit",
max_list_cost: {amount, currency}}`. **Create-only** -- can be changed or removed later, never added. See ?
Session budgets. |
| `metadata`      | object   | No       | User-provided key-value pairs                 |

#### Seeding a session with `initial_events`

Creating a session without `initial_events` registers the session in `idle` and starts no work; the sandbox
is provisioned when the session first needs it. Passing a **non-empty** `initial_events` array starts the
agent loop in the same call -- the session is **created directly in `running`**, never passing through
`idle`. A client that waits for an `idle -> running` transition to know work began will wait forever; check
`status` on the create response instead.

```python
session = client.beta.sessions.create(
    agent=AGENT_ID,
    environment_id=ENVIRONMENT_ID,
    initial_events=[
        {"type": "user.message", "content": [{"type": "text", "text": "Review the auth module."}]},
    ],
)
```

- **Only `user.message` and `user.define_outcome` are accepted**, max **50** events. The tool-result kinds
(`user.tool_confirmation`, `user.tool_result`, `user.custom_tool_result`) are rejected because no agent turn
exists yet, and `user.interrupt` because there is no turn to stop. Unlike a scheduled deployment's
`initial_events`, a session's does **not** accept `system.message`.
- Each event is validated and persisted before the create response returns, in list order, with a
server-assigned ID -- exactly as if you had posted it to the send-events endpoint immediately after creation.
Per-event content rules are the same as on that endpoint.
- **The events are not echoed on the create response.** Read them back with
`sessions.events.list(session.id)` if you need their server-assigned IDs.
- **Validation is all-or-nothing:** if any event fails, the whole request is rejected and no session is
created. An empty list is equivalent to omitting the field.
- Rejections: more than one `user.define_outcome` -> 400; a `user.define_outcome` without a `rubric` -> 400;
more than 100 file-sourced `document` content blocks across the whole list -> 400; a request body over 32 MB
-> 413.

An outcome-driven session is therefore a single call -- pass one `user.define_outcome` in `initial_events`
instead of creating the session and then sending the event (see `shared/managed-agents-outcomes.md`).

Agent configuration fields (passed to `agents.create()`, not `sessions.create()`):

Field	Type	Required	Description
`name`	string	**Yes**	Human-readable name (1-256 chars)
`model`	string or object	**Yes**	Claude model ID (bare string, or an object taking `id`,
`speed`, `effort`, and `inference_geo`). All Claude 4.5+ models supported. See ? Effort on the agent model
and ? Pinning inference geography below.
`system`	string	No	System prompt -- defines the agent's behavior (up to 100K chars)
`tools`	array	No	Encompasses three kinds: (1) pre-built Claude Agent tools
(`agent_toolset_20260401`), (2) MCP tools (`mcp_toolset`), and (3) custom client-side tools. Max 128.
`mcp_servers`	array	No	MCP server connections -- standardized third-party capabilities (e.g.
GitHub, Asana). Max 20, unique names. See `shared/managed-agents-tools.md` -> MCP Servers.
`skills`	array	No	Customized "best-practices" context with progressive disclosure. Max
20. See `shared/managed-agents-tools.md` -> Skills.
```

`description`	string	No	Description of the agent (up to 2048 chars)
`multiagent`	object	No	`{type: "coordinator", agents: [...]}` -- roster this agent may delegate to. See `shared/managed-agents-multiagent.md`.
`metadata`	object	No	Arbitrary key-value pairs (max 16, keys <=64 chars, values <=512 chars)

Session budgets

A **session budget** is an optional hard spend ceiling set at session creation. The platform continuously prices everything the session consumes at **public list rates** (the session's **list cost**) and stops issuing new model requests once that total reaches the cap. A session at its budget **pauses and goes `idle` with `stop_reason: budget_reached`** -- it is not terminated; history and sandbox are preserved, and changing or removing the budget resumes the paused work automatically.

```python
session = client.beta.sessions.create(
    agent=AGENT_ID,
    environment_id=ENVIRONMENT_ID,
    budget={
        "type": "limit",
        "max_list_cost": {"amount": "2500", "currency": "USD"},  # minor units: "2500" = $25.00
    },
)
```

- `type` is always `"limit"`. `max_list_cost.amount` is the amount in **minor units of the currency (cents), as an integer string** with no leading zeros, > 0 -- `"2500"` is $25.00, `"50"` is fifty cents. A string rather than a number so no float rounding is ever applied; decimal forms such as `"25.00"` are rejected. `max_list_cost.currency` is uppercase ISO-4217; **`USD` is the only supported currency.**
- **What counts toward list cost:** model tokens at each served model's list price, web searches at $10 per 1,000, and session running time at $0.08/hour. List cost is *not* your contracted price -- with negotiated discounts, the session hits the cap when the list-price total does, and billed spend may be lower.
- **Enforcement is a pre-request gate:** before every model request the platform checks whether consumed list cost has reached the cap and pauses the thread if it has; the request that crosses the cap completes, so the final figure can exceed the cap by at most one model request per running thread. Treat the budget as a bound on new work, not an exact stop.
- The reported `list_cost` is **rounded to the nearest cent** while enforcement compares exact amounts -- rounding can move the reported figure up to half a cent in either direction from the exact amount, so a session whose reported `list_cost` equals its cap may not yet be paused. Treat `stop_reason: budget_reached` (or the 400 on `user.message`), not the reported figure, as the signal that the cap was reached.
- **Create-only.** Adding a budget to a session created without one is a 400. Updates accept exactly two changes: **change the cap** (the new value can be higher or lower than the old cap, but must be strictly greater than the consumed list cost, else 400: `budget.max_list_cost must be greater than the session's consumed list cost`) or **remove** (`budget: null` -- the `session.updated` event carries `budget: null` rather than a separate flag). Because the consumed cost usually sits a fraction past the old cap when the session pauses, base the new value on the session's reported `usage.list_cost`, not the old `max_list_cost`. **Removal is one-way**: a removed budget can never be re-added; to keep a cap, change it instead.
- **At the cap, only settle events are accepted** -- events that resolve work already in progress rather than starting new work: `user.tool_confirmation`, `user.tool_result`, `user.custom_tool_result`, `user.interrupt`. A `user.interrupt` sent while the session is paused at its budget (all threads paused at the cap) is accepted and ignored: it does not appear in the event list and changes nothing. Raise or remove the budget to continue. Anything that starts new work (e.g. `user.message`) is a 400 naming that list. No event resumes the session -- only a budget change/removal does.
- **Multiagent:** one budget shared across all threads, no per-thread caps. Threads pause independently; each thread's consumption is priced at its own served model. A pending tool ask outranks the cap: a session with one thread at `requires_action` and another at `budget_reached` reports `requires_action` at the session level -- answer it as usual (settle events aren't blocked).
- **Models without a list price can't be budgeted:** a budgeted create whose agent (or any roster agent, including the advisor's model) uses an unpriced model is a 400. If a running budgeted session's usage comes to include one, changing the budget is rejected -- remove the budget to resume.
- Stream behavior at the cap and the `session.usage` event: `shared/managed-agents-events.md` ? Reaching a session budget.
- Scheduled deployments can carry a budget too -- copied onto each fired session, with different update semantics (clearable and re-addable): `shared/managed-agents-scheduled-deployments.md` ? Deployment budgets.

> **Not the same thing as Messages-API task budgets.** Session budgets are hard, dollar-denominated, platform-enforced caps on one session. `task_budget` on the Messages API is an advisory, token-denominated budget the model uses to pace itself within one agentic loop.

```
## Agents

**This is where every Managed Agents flow begins.** The agent object is a persisted, versioned configuration
-- you create it once, then reference it by ID every time you start a session. No agent -> no session.

### Agent Object

The API is **flat** -- `model`, `system`, `tools` etc. are top-level fields, not wrapped in an `agent:{}`
sub-object.

| Field              | Type     | Required | Description                                          |
| ------------------ | -------- | -------- | ---------------------------------------------------- |
| `name`             | string   | Yes      | Human-readable name                                  |
| `model`            | string or object | Yes | Claude model ID -- bare string, or `{id, speed?, effort?,
inference_geo?}` |
| `system`           | string   | No       | System prompt                                        |
| `tools`            | array    | No       | Agent toolset / MCP toolset / custom tools           |
| `mcp_servers`      | array    | No       | MCP server connections                               |
| `skills`           | array    | No       | Skill references (max 20)                            |
| `description`      | string   | No       | Description of the agent                             |
| `multiagent`       | object   | No       | Coordinator roster -- see `shared/managed-agents-multiagent.md` |
| `metadata`         | object   | No       | Arbitrary key-value pairs                            |

### Lifecycle: create once, run many, update in place

The agent is a **persistent resource**, not a per-run parameter. The intended pattern:

~~~
+- setup (once) ----------+     +- runtime (every invocation) -+
| agents.create()         |     | sessions.create(              |
|   -> store agent_id     | ---> |   agent={type:..., id: ID}   |
|     in config/env/db    |     | )                             |
+-------------------------+     +-------------------------------+
~~~

**Anti-pattern:** calling `agents.create()` at the top of every script run. This accumulates orphaned agent
objects, pays create latency on every invocation, and defeats the versioning model. If you see
`agents.create()` in a function that's called per-request or per-cron-tick, that's wrong -- hoist it to
one-time setup and persist the ID.

> **Recommended -- define agents and environments as YAML + apply via the `ant` CLI.** The split is **CLI for
the control plane, SDK for the data plane**: agents and environments are relatively static resources you
manage with `ant` (version-controlled YAML, applied from CI); sessions are dynamic and driven by your
application through the SDK. See `shared/anthropic-cli.md` -> *Version-controlled Managed Agents resources*
for the `ant beta:agents create < agent.yaml` / `update --version N` flow. The SDK `agents.create()` call
shown elsewhere in this doc is the in-code equivalent -- use it when you need to provision programmatically,
but prefer the YAML flow for anything a human maintains.

### Effort on the agent model

Pass `model` as an object to set the effort level: `{"id": "claude-opus-5", "effort": "high"}`. `effort`
accepts a level string (`low`, `medium`, `high`, `xhigh`, `max`) or an object such as `{"type": "high"}`. The
create/update response echoes it in object form and fills in omitted `model` fields with their defaults.

> ?? **Effort is agent configuration only.** An `effort` set inside a per-session `model` override is **not
applied** -- the session runs at the agent's effort. To change effort you must update the agent (or point the
session at a different agent). This is the one field where the override form silently does nothing rather
than erroring.

The same object form carries `speed` for fast mode: `{"id": "claude-opus-5", "speed": "fast"}`.

### Pinning inference geography (`inference_geo`)

The `model` object also takes `inference_geo` to pin the geography that serves the agent's model requests:
`{"id": "claude-opus-5", "inference_geo": "us"}`. Accepts `"us"` or `"global"` -- and unlike the Messages
API, where `inference_geo` is a top-level request parameter, here it is always nested inside `model`, never
top-level. When unset, each model request follows the workspace's default inference geo at the time it's
served.
```

```
- **Validated at every stage:** the pin is checked against the workspace's `allowed_inference_geos` when the
agent is saved, when a session is created from it, and on every turn the session serves. If the workspace
allowlist later narrows so the pin is no longer allowed, new sessions can't be created from the agent and
**running sessions refuse further turns** -- pins are never grandfathered (workspaces rely on them for
compliance).
- Setting `inference_geo` on a model that doesn't support geographic inference pinning returns a 400.
- **Fixed for a session's lifetime** -- the pin can't change mid-session. Set it on the agent, or set/clear
it for one session with a `model` override at session create (see ? Override agent configuration for a
session).
- **Multiagent rosters must be geo-uniform:** the coordinator's pin and every roster member's must all be the
same value or all be unset -- see `shared/managed-agents-multiagent.md`.
- Unlike `effort`, an `inference_geo` inside a per-session `model` override **is applied** -- and because
overrides replace the `model` object in full, an override that *omits* `inference_geo` clears the agent's pin
for that session.

### Versioning

Each `POST /v1/agents/{id}` (update) creates a new immutable version -- a sequential integer, starting at 1
and incrementing on each update. The agent's history is append-only -- you can't edit a past version.

**`version` on update is optional.** Supply it for optimistic concurrency, or omit it to apply the update
unconditionally:

| `version` | Behavior | Fits |
|---|---|---|
| Supplied (must be >= 1) | 409 if it doesn't match the agent's current version -- **even when the fields you
send already equal the stored values**. Re-read and retry. | Interactive callers; the recommended default |
| Omitted | Applies unconditionally. The most recent update silently replaces any concurrent one, with no
error to either caller. | Declarative apply loops -- e.g. a CI job syncing checked-in agent definitions,
where the loop owns the agent |

**Update semantics.** Omitted fields are preserved. Scalar fields (`model`, `system`, `name`, `description`)
are replaced; `system` and `description` can be cleared with `null`, while `model` and `name` cannot. Array
fields (`tools`, `mcp_servers`, `skills`) are replaced wholesale -- `null` or `[]` clears them. **`effort` is
the sole exception inside a `model` object you supply:** if the model `id` is unchanged, omitting `effort`
leaves the stored level alone; if you change the `id`, an omitted `effort` resets to the new model's default.
Other `model` fields are replaced along with the object -- **supplying `model` without `inference_geo` clears
the agent's inference geo pin.**

**Why version:**
- **Reproducibility** -- pin a session to a known-good config: `{type: "agent", id, version: 3}`
- **Safe iteration** -- update the agent without breaking sessions already running on the old version
- **Rollback** -- if a new system prompt regresses, pin new sessions back to the prior version while you debug

**`version` is optional.** Omit it (or use the string shorthand `agent="agent_abc123"`) to get the latest
version at session-creation time. Pass it explicitly (`{type: "agent", id, version: N}`) to pin for
reproducibility.

**Getting the version to pin:** `agents.create()` and `agents.update()` both return `version` in the
response. Store it alongside `agent_id`. To fetch the current latest for an existing agent: `GET
/v1/agents/{id}` -> `.version`.

**When to update vs create new:** Update (`POST /v1/agents/{id}`) when it's conceptually the same agent with
tweaked behavior (better prompt, extra tool). Create a new agent when it's a different persona/purpose. Rule
of thumb: if you'd give it the same `name`, update.

### Agent Endpoints

| Operation        | Method   | Path                                  |
| ---------------- | -------- | ------------------------------------- |
| Create           | `POST`   | `/v1/agents`                          |
| List             | `GET`    | `/v1/agents`                          |
| Get              | `GET`    | `/v1/agents/{id}`                     |
| Update           | `POST`   | `/v1/agents/{id}`                     |
| Archive          | `POST`   | `/v1/agents/{id}/archive`             |

> ?? **Archive is permanent.** Archiving makes the agent read-only: existing sessions continue to run, but
**new sessions cannot reference it**, and there is no unarchive. Since agents have no `delete`, this is the
terminal lifecycle state. Never archive a production agent as routine cleanup -- confirm with the user first.
```

```
### Using an Agent in a Session

Reference the agent by string ID (latest version) or by object with an explicit version:

```python
# String shorthand -- uses the agent's latest version
session = client.beta.sessions.create(
    agent=agent.id,
    environment_id=environment_id,
)

# Or pin to a specific version (int)
session = client.beta.sessions.create(
    agent={"type": "agent", "id": agent.id, "version": agent.version},
    environment_id=environment_id,
)
```

Override agent configuration for a session

The third `agent` form, `agent_with_overrides`, replaces parts of the agent's configuration for **a single
session** -- try a different model or grant an extra tool without versioning the agent. Pass `id` (and
optionally `version`; omitted = latest, same default as the other two forms) plus any of `model`, `system`,
`tools`, `mcp_servers`, `skills`:

```python
session = client.beta.sessions.create(
    agent={
        "type": "agent_with_overrides",
        "id": agent.id,
        "model": "claude-opus-5",   # replace the agent's model for this session
        "system": None,           # clear the system prompt for this session
    },
    environment_id=environment_id,
)
```

Each overridable field follows tri-state rules:
- **Omit** -> the session inherits the value from the referenced agent version.
- **`null` (or `[]` for list fields)** -> the session runs with that field cleared. Applies in full to
`system` and `skills`. Three exceptions: `model` is never clearable (`model: null` -> 400
`agent_model_required`); clearing `tools` returns 400 when the session's effective `skills` is non-empty
(skills require the `read` tool); and clearing `mcp_servers` returns 400 when the effective `tools` still
contains an `mcp_toolset` referencing one of the agent's servers -- override `tools` in the same request to
drop those entries, then clear `mcp_servers`.
- **A value** -> replaces the agent's value **in full**. Overrides never merge -- a `tools` override must
list every tool the session should have. One exception: an `effort` level inside a `model` override is **not
applied** (set it on the agent instead -- see ? Effort on the agent model). An `inference_geo` inside a
`model` override **is** applied -- and because the object is replaced in full, an override that omits it
clears the agent's pin, so the session follows the workspace's default inference geo. The overridden value is
validated against the workspace's `allowed_inference_geos` at session create.

Overrides are session-local: they do **not** modify the agent resource or create a new agent version. The
response's `agent` object reflects the post-override configuration, while its `id` and `version` still
identify the base agent -- so you can trace a session back to its base. In multiagent sessions, overrides
apply to the coordinator and its `{type: "self"}` copies; roster agents referenced by ID always use their own
as-created configuration (see `shared/managed-agents-multiagent.md`).

Updating the agent configuration mid-session

`sessions.update()` can change `agent.tools` and `agent.mcp_servers` (including permission policies) on an
existing session. This is a **session-local override** -- it does not create a new agent version and does
not propagate back to the agent object. The provided arrays are **full replacements**; to append one tool,
`GET` the session, modify, and `POST` back. The session must be `idle` -- interrupt first if running.
`vault_ids` is **create-only**: the update param exists in the SDK but is rejected by the API ("Not yet
supported") -- attach vaults when you create the session.

Among the agent-configuration fields, only `tools` and `mcp_servers` can change after a session is created --
to run with a `model`, `system`, or `skills` other than the agent's values, use `agent_with_overrides` at
create time (above). (`title`, `metadata`, and `budget` have their own session-update paths -- see ? Session
```

operations / ? Session budgets.) The agent's model configuration -- including its `inference_geo` pin -- and its configured `system` field are fixed for the session's lifetime; you can still **append system-level context between turns** by sending a `system.message` event (see `shared/managed-agents-events.md` ? Adding system context mid-session).

```python
client.beta.sessions.update(
    session.id,
    agent={
        "tools": [
            {"type": "agent_toolset_20260401"},
            {"type": "mcp_toolset", "mcp_server_name": "linear"},
        ],
        "mcp_servers": [{"type": "url", "name": "linear", "url": "https://mcp.linear.app/sse"}],
    },
)
```
</doc>

<doc path="shared/managed-agents-environments.md">
Managed Agents -- Environments & Resources

Environments

Creating a session requires an `environment_id`. Environments are **reusable configuration templates** for spinning up containers in Anthropic's infrastructure -- you might create different environments for different use cases (e.g. data visualization vs web development, with different package sets). Anthropic handles scaling, container lifecycle, and work orchestration.

Environment names must be unique. Creating an environment with an existing name returns 409.

Networking

Network Policy	Description	
---	---	
`unrestricted`	Full egress (except legal blocklist)	
`limited`	Deny-by-default; opt in via `allowed_hosts` / `allow_package_managers` / `allow_mcp_servers`	

```json
{
  "networking": {
    "type": "limited",
    "allow_package_managers": true,
    "allow_mcp_servers": true,
    "allowed_hosts": ["api.example.com"]
  }
}
```

All three `limited` fields are optional. `allow_package_managers` (default `false`) permits PyPI/npm/etc.; `allow_mcp_servers` (default `false`) permits the agent's configured MCP server endpoints without listing them in `allowed_hosts`.

MCP caveat: Under `limited` networking, either set `allow_mcp_servers: true` or add each MCP server domain to `allowed_hosts`. Otherwise the container can't reach them and tools silently fail.

Creating an environment

The SDK adds `managed-agents-2026-04-01` automatically. TypeScript:

```ts
const env = await client.beta.environments.create({
  name: "my_env",
  config: {
    type: "cloud",
    networking: { type: "unrestricted" },
  },
});
```

```
### Self-hosted sandboxes

To run tool execution in **your own infrastructure** instead of Anthropic's, set `config: {type:
"self_hosted"}` -- the agent loop stays on Anthropic's side, but `bash` / file ops / code execute in a
container you control via an outbound-polling worker. The `networking` block does not apply (you control
egress). Resource mounting (`file`, `github_repository`) and memory stores behave differently -- see
`shared/managed-agents-self-hosted-sandboxes.md` for the worker, credentials, and cloud-vs-self-hosted
comparison.

### Environment CRUD

| Operation        | Method   | Path                                          | Notes |
| ---------------- | -------- | --------------------------------------------- | ----- |
| Create           | `POST`   | `/v1/environments`                            | |
| List             | `GET`    | `/v1/environments`                            | Paginated (`limit`, `after_id`,
`before_id`) |
| Get              | `GET`    | `/v1/environments/{id}`                       | |
| Update           | `POST`   | `/v1/environments/{id}`                       | Changes apply only to **new**
containers; existing sessions keep their original config |
| Delete           | `DELETE` | `/v1/environments/{id}`                       | Returns 204. |
| Archive          | `POST`   | `/v1/environments/{id}/archive`               | Makes it **read-only**; existing
sessions continue, new sessions cannot reference it. No unarchive -- terminal state. |

---

## Resources

Attach files, GitHub repositories, and memory stores to a session. Resources are resolved during session
creation, so a bad `file_id` or an unreachable repo surfaces on the create call rather than mid-run. Creating
a session does **not** by itself start work or provision the sandbox -- without `initial_events` the session
is only registered, and the sandbox comes up when the session first needs it (see
`shared/managed-agents-core.md` -> Seeding a session with `initial_events`). Max **999 file resources** per
session. Multiple GitHub repositories per session are supported. For `type: "memory_store"` resources
(persistent cross-session memory -- max 8 per session), see `shared/managed-agents-memory.md`.

### File Uploads (input -- host -> agent)

Upload a file first via the Files API, then reference by `file_id` + `mount_path`:

```ts
// 1. Upload
const file = await client.beta.files.upload({
  file: fs.createReadStream("data.csv"),
  purpose: "agent",
});

// 2. Attach as a session resource
const session = await client.beta.sessions.create({
  agent: agent.id,
  environment_id: envId,
  resources: [
    { type: "file", file_id: file.id, mount_path: "/workspace/data.csv" }
  ],
});
```

`mount_path` is required and must be absolute. Parent directories are created automatically. Agent
working directory defaults to `/workspace`. Files are mounted read-only -- the agent writes modified versions
to new paths.

Session outputs (output -- agent -> host)

The agent can write files to `/mnt/session/outputs/` during a session. These are automatically captured by
the Files API and can be listed and downloaded afterwards:

```ts
// After the turn completes, list output files scoped to this session:
for await (const f of client.beta.files.list({
  scope_id: session.id,
```
```

```
  betas: ["managed-agents-2026-04-01"],
})) {
  console.log(f.filename, f.size_bytes);
  const resp = await client.beta.files.download(f.id);
  const text = await resp.text();
}
```

Requirements:
- The `write` tool (or `bash`) must be enabled for the agent to create output files.
- Session-scoped `files.list` / `files.download` captures outputs written to `/mnt/session/outputs/`.
- The filter parameter is **`scope_id`** (REST query param `?scope_id=<session_id>`). The SDK's files resource auto-adds only the `files-api-2025-04-14` header, so pass `betas: ["managed-agents-2026-04-01"]` explicitly (or both headers on raw HTTP) -- without it the API may reject `scope_id` as an unknown field. Requires `@anthropic-ai/sdk` >= 0.88.0 / `anthropic` (Python) >= 0.92.0 -- older versions don't type `scope_id`. The `ant` CLI does **not** expose this flag yet; use the SDK or curl.
- Pass the session ID returned by `sessions.create()` verbatim (e.g. `sesn_011CZx...`) -- the API validates the prefix.
- There's a brief indexing lag (~1-3s) between `session.status_idle` and output files appearing in `files.list`. Retry once or twice if empty.

> **Fallback when `scope_id` filtering is unavailable** (older SDK, or endpoint returns an error): send a follow-up `user.message` asking the agent to `read` each file under `/mnt/session/outputs/` and return the contents. The agent streams the file bodies back as `agent.message` text. This works for text files only and costs output tokens -- use it to unblock, not as the primary path.

This gives you a bidirectional file bridge: upload reference data in, download agent artifacts out.

GitHub Repositories

Clones a GitHub repository into the session container during initialization, before the agent begins execution. The agent can read, edit, commit, and push via `bash` (`git`). Multiple repositories per session are supported -- add one `resources` entry per repo. Repositories are cached, so future sessions that use the same repository start faster.

Mounting a repository also loads any skills stored in its root `.claude/skills` directory -- discovered once per session, from the repository state checked out at session start (cloud sandboxes only). See `shared/managed-agents-tools.md` -> Skills from a GitHub repository.

Repositories are attached for the lifetime of the session -- to change which repositories are mounted, create a new session. You **can** rotate a repository's `authorization_token` on a running session via `client.beta.sessions.resources.update(resource_id, {session_id, authorization_token})`; the resource `id` is returned at session creation and by `resources.list()`.

Fields:

Field	Required	Notes
`type`	?	`"github_repository"`
`url`	?	The GitHub repository URL
`authorization_token`	?	GitHub Personal Access Token with repository access. **Never echoed in API responses.**
`mount_path`	?	Path where the repository will be cloned. Defaults to `/workspace/<repo-name>`.
`checkout`	?	`{type: "branch", name: "..."}` or `{type: "commit", sha: "..."}`. Defaults to the repo's default branch.

Token permission levels (fine-grained PATs):
- `Contents: Read` -- clone only
- `Contents: Read and write` -- push changes and create pull requests

How auth works: `authorization_token` is never placed inside the container. `git pull` / `git push` and GitHub REST calls against the attached repository are routed through an Anthropic-side git proxy that injects the token after the request leaves the sandbox. Code running in the container -- including anything the agent writes -- cannot read or exfiltrate it.

> ?? **To generate pull requests** you also need GitHub **MCP server** access -- the `github_repository` resource gives filesystem + git access only. See `shared/managed-agents-tools.md` -> MCP Servers. The PR workflow is: edit files in the mounted repo -> push branch via `bash` (authenticated via the git proxy using `authorization_token`) -> create PR via the MCP `create_pull_request` tool (authenticated via the vault).

TypeScript:

```ts
// 1. Create the agent -- declare GitHub MCP (no auth here)
const agent = await client.beta.agents.create(
  {
    name: 'GitHub Agent',
    model: 'claude-opus-5',
    mcp_servers: [
      { type: 'url', name: 'github', url: 'https://api.githubcopilot.com/mcp/' },
    ],
    tools: [
      { type: 'agent_toolset_20260401', default_config: { enabled: true } },
      { type: 'mcp_toolset', mcp_server_name: 'github' },
    ],
  },
);

// 2. Start a session -- attach vault for MCP auth + mount the repo
const session = await client.beta.sessions.create({
  agent: agent.id,
  environment_id: envId,
  vault_ids: [vaultId],  // vault contains the GitHub MCP OAuth credential
  resources: [
    {
      type: 'github_repository',
      url: 'https://github.com/owner/repo',
      authorization_token: process.env.GITHUB_TOKEN,  // repo clone token (!= MCP auth)
      checkout: { type: 'branch', name: 'main' },
    },
  ],
});
```

Python:

```python
import os

agent = client.beta.agents.create(
    name="GitHub Agent",
    model="claude-opus-5",
    mcp_servers=[{
        "type": "url",
        "name": "github",
        "url": "https://api.githubcopilot.com/mcp/",
    }],
    tools=[
        {"type": "agent_toolset_20260401", "default_config": {"enabled": True}},
        {"type": "mcp_toolset", "mcp_server_name": "github"},
    ],
)

session = client.beta.sessions.create(
    agent=agent.id,
    environment_id=env_id,
    vault_ids=[vault_id],  # vault contains the GitHub MCP OAuth credential
    resources=[{
        "type": "github_repository",
        "url": "https://github.com/owner/repo",
        "authorization_token": os.environ["GITHUB_TOKEN"],  # repo clone token (!= MCP auth)
        "checkout": {"type": "branch", "name": "main"},
    }],
)
```

Files API

Upload and manage files for use as session resources, and download files the agent wrote to `/mnt/session/outputs/`.

Operation	Method	Path	SDK
Upload	`POST`	`/v1/files`	`client.beta.files.upload({ file })`
List	`GET`	`/v1/files?scope_id=...`	`client.beta.files.list({ scope_id, betas: ["managed-agents-2026-04-01"] })`
Get Metadata	`GET`	`/v1/files/{id}`	`client.beta.files.retrieveMetadata(id)`
Download	`GET`	`/v1/files/{id}/content`	`client.beta.files.download(id)` -> `Response`
Delete	`DELETE`	`/v1/files/{id}`	`client.beta.files.delete(id)`

The `scope_id` filter on List scopes the results to files written to `/mnt/session/outputs/` by that session. Without the filter, you get all files uploaded to your account.

<doc path="shared/managed-agents-events.md">
Managed Agents -- Events & Steering

Events

Sending Events

Send events to a session via `POST /v1/sessions/{id}/events`.

Event Type	When to Send
`user.message`	Send a user message
`user.interrupt`	Interrupt the agent while it's running
`user.tool_confirmation`	Approve/deny a tool call (when `always_ask` policy)
`user.custom_tool_result`	Provide result for a custom tool call
`user.define_outcome`	Start a rubric-graded iterate loop -- see `shared/managed-agents-outcomes.md`
`system.message`	Append privileged system-level context for this turn and every turn after it; see ? Adding system context mid-session

Adding system context mid-session (`system.message`)

The `system` field on the agent definition sets the top-level system prompt and is fixed for the session's lifetime. A `system.message` event **appends** to the session's system context as a `role: "system"` turn -- it does not replace that prompt. The content applies to the accompanying turn and all subsequent turns. Use it for a different persona, revised constraints, or runtime-fetched context that should shape behavior going forward:

```python
client.beta.sessions.events.send(
    session.id,
    events=[
        {
            "type": "system.message",
            "content": [
                {"type": "text", "text": "The user's current timezone is America/New_York."},
            ],
        },
    ],
)
```

Constraints:

- **Model-gated: Claude Opus 5, Claude Opus 4.8, Claude Sonnet 5, Claude Fable 5, and Claude Mythos 5.** Only the agent's **primary** model is checked -- `system.message` lands on the primary thread only, so subagent models are not considered. On an unsupported primary model the event is rejected with a `model_does_not_support_mid_conversation_system` validation error.
- **While the session is idle with `stop_reason: requires_action`** (blocked on `user.custom_tool_result` / `user.tool_confirmation`), a `system.message` is accepted **only when it trails a tool result event in the same request**. Sent on its own -- or alongside a `user.message` -- it is rejected until the pending tool events are resolved.
- `content` accepts 1-1000 text items.

```
### Receiving Events

Three methods:

1. **Streaming (SSE)**: `GET /v1/sessions/{id}/events/stream` -- real-time Server-Sent Events. **Long-lived**
-- the server sends periodic heartbeats to keep the connection alive.
2. **Polling**: `GET /v1/sessions/{id}/events` -- paginated event list (query params: `limit` default 1000,
`page`). **Returns immediately** -- this is a plain paginated GET, not a long-poll.
3. **Webhooks**: Anthropic POSTs session state transitions to your HTTPS endpoint -- thin payloads (IDs
only), HMAC-signed, Console-registered. See `shared/managed-agents-webhooks.md`.

All **persisted** events carry `id`, `type`, and `processed_at` (ISO 8601), set when the event finishes
processing. On events you send, `processed_at` is `null` while the event is still queued behind earlier ones
-- **except** `user.define_outcome`, `user.custom_tool_result`, and `user.tool_result`, which are processed
on receipt and echoed back with `processed_at` already populated. The stream-only `event_start` /
`event_delta` preview events (see ? Live previews) carry only the `id` of the event they preview.

> ?? **Robust polling (raw HTTP).** If you bypass the SDK and roll your own poll loop, don't rely on
`requests` or `httpx` timeouts as wall-clock caps -- they're **per-chunk** read timeouts, reset every time a
byte arrives. A trickling response (heartbeats, a wedged chunked-encoding body, a misbehaving proxy) can keep
the call blocked indefinitely even with `timeout=(5, 60)` or `httpx.Timeout(120)`. Neither library has a
"total wall-clock" timeout built in. For a hard deadline: track `time.monotonic()` at the loop level and
break/cancel if a single request exceeds your budget (e.g. via a watchdog thread, or `asyncio.wait_for()`
around async httpx). **Prefer the SDK** -- `client.beta.sessions.events.stream()` and
`client.beta.sessions.events.list()` handle timeout + retry sanely.
>
> If `GET /v1/sessions/{id}/events` (paginated) ever hangs after headers, you've likely hit `GET
/v1/sessions/{id}/events/stream` by mistake or a server-side stall -- report it; don't treat it as a
client-config problem.

### Event Types (Received)

Event types use dot notation, grouped by namespace:

| Event Type | Description |
| --- | --- |
| `agent.message` | Agent text output |
| `agent.thinking` | Progress signal that the agent is thinking -- it does **not** carry the thinking content
|
| `agent.tool_use` | Agent used a built-in tool (`agent_toolset_20260401`) |
| `agent.tool_result` | Result from a built-in tool |
| `agent.mcp_tool_use` | Agent used an MCP tool |
| `agent.mcp_tool_result` | Result from an MCP tool |
| `agent.custom_tool_use` | Agent invoked a custom tool -- session goes idle, you respond with
`user.custom_tool_result` |
| `agent.thread_context_compacted` | Conversation context was compacted |
| `session.status_idle` | Agent has finished the current task, and is awaiting input. It's either waiting for
input to continue working via a `user.message`, blocked awaiting a `user.custom_tool_result` or
`user.tool_confirmation`, or paused because the session budget cap was reached. The `stop_reason` attached
contains more information about why the Agent has stopped working. |
| `session.status_running` | Session has starting running, and the Agent is actively doing work. |
| `session.status_rescheduled` | Session is (re)scheduling after a retryable error has occurred, ready to be
picked up by the orchestration system. |
| `session.status_terminated` | Session ended and is irreversibly unusable -- **on completion or on error**,
not error-only. |
| `session.updated` | A session update changed at least one field -- carries only the changed fields (a
budget removal carries `budget: null`) |
| `session.usage` | Snapshot of the session's cumulative usage and tracked list cost -- see ? Reaching a
session budget below |
| `session.error` | Error occurred during processing |
| `span.model_request_start` | Model inference started |
| `span.model_request_end` | Model inference completed |
| `span.outcome_evaluation_start` / `_ongoing` / `_end` | Grader progress for outcome-oriented sessions --
see `shared/managed-agents-outcomes.md` |
| `session.thread_created` | Subagent thread spawned (multiagent), or an advisor consultation started (thread
name `anthropic.advisor`) -- see `shared/managed-agents-multiagent.md` |
| `session.thread_status_running` / `_idle` / `_rescheduled` / `_terminated` | Thread status transitions --
mostly seen in multiagent sessions, but a single-agent session's primary thread also emits `_idle` when
pausing at a session budget (? Reaching a session budget). `_idle` carries `stop_reason`. |
```

| `agent.thread_message_sent` / `_received` | Cross-thread message, carries `to_session_thread_id` / `from_session_thread_id` (multiagent) |

The stream also echoes back user-sent events (`user.message`, `user.interrupt`, `user.tool_confirmation`, `user.tool_result`, `user.custom_tool_result`, `user.define_outcome`) -- except a `user.interrupt` sent while the session is paused at its budget, which is accepted and ignored and never appears (? Reaching a session budget).

Stream-only delta preview events (`event_start`, `event_delta`) are the one exception to the `{domain}.{action}` naming convention -- see ? Live previews below; they never appear in `GET /v1/sessions/{id}/events`.

Live previews

By default, assistant text reaches the stream as buffered `agent.message` events -- emitted only after the model request that produced them finishes. **Live previews** let you render that text incrementally while the model is still generating. The buffered `agent.message` is always the authoritative record; a client that ignores previews still receives a complete, correct stream. The wire format is **not** Messages-API streaming: the delta type is `content_delta`, not `content_block_delta`, so Messages-API accumulator code does not carry over unchanged.

Opt in per stream connection by adding the `event_deltas[]` query parameter, repeated once per event type to preview. Accepted values: `agent.message`, `agent.thinking` -- any other value returns a 400, as does a request with more than 100 values. **Both stream endpoints accept it:** the session-level stream (`GET /v1/sessions/{id}/events/stream`) and each session thread's own stream (`GET /v1/sessions/{sid}/threads/{tid}/stream`). In a shell, quote the URL or percent-encode the brackets as `%5B%5D` -- bare `[]` is a glob pattern.

Previews are thread-scoped. A connection previews only the thread it is reading. A child thread's previews are delivered on that child's stream and are *never* cross-posted to the session-level stream, whose previews stay scoped to the primary thread. To watch a subagent's text as the model generates it, open that subagent's thread stream -- see `shared/managed-agents-multiagent.md`. Run one accumulator instance per connection.

```python
stream = client.beta.sessions.events.stream(
    session_id=session.id,
    event_deltas=["agent.message"],
)
```

When a previewed event begins, the stream emits an `event_start` carrying the upcoming event's `type` and `id`; for `agent.message` it's followed by `event_delta` events carrying incremental text:

```json
{"type": "event_start", "event": {"type": "agent.message", "id": "sevt_01abc..."}}
{"type": "event_delta", "event_id": "sevt_01abc...", "delta": {"type": "content_delta", "index": 0,
"content": {"type": "text", "text": "Here is the summary"}}}
```

`event_start` and `event_delta` have no `id` or `processed_at` of their own -- the only identifier they carry is the `id` of the event they preview. For `agent.thinking`, **only** the `event_start` is emitted (a "thinking has started" signal) -- no deltas follow, and the buffered `agent.thinking` that concludes the preview carries no thinking content either. It is a progress signal, not a content carrier; there is nothing to read out of it.

Accumulate-and-reconcile pattern. Treat the preview as a scratch buffer keyed by `(event_id, index)`. On `event_start`, create an empty entry for the announced `id`. On each `event_delta`, append `delta.content.text` to `(event_id, delta.index)` and render the running text. When the buffered `agent.message` arrives, match it by `id`, **discard the accumulated preview**, and render the message's content instead. The identifiers always line up: `event_start.event.id`, every `event_delta.event_id`, and the buffered event's `id` are the same value. On a normal turn the order is fixed: `session.status_running` -> `span.model_request_start` -> `event_start` -> `event_delta`* -> buffered `agent.message` -> `span.model_request_end`. If the turn errors or is interrupted the buffered event may never arrive, but `span.model_request_end` still does -- close any unreconciled preview when you see it. Python/TypeScript/Go SDKs ship an accumulator helper that implements this; in other SDKs apply the manual pattern to the generated event types.

```
**Two guarantees the pattern relies on:** concatenating a preview's deltas in arrival order, keyed by
`(event_id, index)`, yields a *prefix* of `content[index].text` in the buffered event (a prefix, not
necessarily the whole text -- deltas may be shed under load); and a connection emits at most one
`event_start` per `event_id`, with the buffered event as the last thing that connection delivers for that
`id`.

**Limitations:**
- **Best effort** -- under load the server may shed deltas for an event; you receive a contiguous prefix and
then no further deltas for that event. The buffered `agent.message` still arrives complete. Never treat an
accumulated preview as final.
- **No replay on reconnect** -- deltas are delivered only to the connection that opted in, while it's open;
this holds for the session-level stream and each thread stream alike. A connection opened after a model
request started receives no deltas for that in-flight event. After a drop, follow the consolidation pattern
in ? Reconnecting after a dropped stream -- the history fetch returns any buffered events emitted during the
gap; missed deltas cannot be re-requested.
- **One thread, text only** -- previews cover assistant text on the thread the connection is reading. Tool
use, tool results, MCP results, and activity on any *other* thread are never previewed on that connection.
- **Never persisted** -- `event_start` / `event_delta` exist only on the live SSE stream, never in `GET
/v1/sessions/{id}/events` or any thread's event history.

**Troubleshooting:**

| You see | What it means |
| --- | --- |
| Buffered events but no `event_start` / `event_delta` | This connection didn't opt in (`event_deltas[]` is
per connection, not per session), or the turn ran on a different thread. List `GET
/v1/sessions/{sid}/threads` to find which one ran. |
| 404 on the stream URL | Wrong path or ID, or the request carries no managed-agents beta header -- the
thread endpoints are beta-gated, so without it they don't exist. The thread path is `/threads/{tid}/stream`,
**not** `/threads/{tid}/events/stream` (which doesn't exist) and not `/events/stream` (session level only). |
| 400 naming `event_deltas` | Only `agent.message` and `agent.thinking` are accepted, max 100 values. |

---

## Steering Patterns

Practical patterns for driving a session via the events surface.

### Stream-first ordering

**Open the stream before sending events.** The stream only delivers events that occur *after* it's opened --
it does not replay current state or historical events. If you send a message first and open the stream
second, early events (including fast status transitions) arrive buffered in a single batch and you lose the
ability to react to them in real time.

```ts
// ? Correct -- stream and send concurrently
const [response] = await Promise.all([
  streamEvents(sessionId),   // opens SSE connection
  sendMessage(sessionId, text),
]);

// ? Wrong -- events before stream opens arrive as a single buffered batch
await sendMessage(sessionId, text);
const response = await streamEvents(sessionId);
```

For full history, use `GET /v1/sessions/{id}/events` (paginated list) -- the stream only gives you live
events from connection onward.

Reconnecting after a dropped stream

The SSE stream has no replay. If your connection drops (httpx read timeout, network blip) and you
reconnect, you only get events emitted *after* reconnection. Any events emitted during the gap are lost from
the stream.

The consolidation pattern: on every (re)connect, overlap the stream with a history fetch and dedupe by
event ID:

```python
```
```

```
def connect_with_consolidation(client, session_id):
    # 1. Open the SSE stream first
    stream = client.beta.sessions.events.stream(session_id=session_id)

    # 2. Fetch history to cover any gap
    history = client.beta.sessions.events.list(
        session_id=session_id,
    )

    # 3. Yield history first, then stream -- dedupe by event.id
    seen = set()
    for ev in history.data:
        seen.add(ev.id)
        yield ev
    for ev in stream:
        if ev.id not in seen:
            seen.add(ev.id)
            yield ev
```

Message queuing

You don't have to wait for a response before sending the next message. User events are queued server-side and processed in order. This is useful for chat bridges where the user sends rapid follow-ups:

```ts
// All three go into one session; agent processes them in order
await sendMessage(sessionId, "Summarize the README");
await sendMessage(sessionId, "Actually also check the CONTRIBUTING guide");
await sendMessage(sessionId, "And compare the two");
// Stream once -- agent responds to all three as a coherent turn
```

Events can be sent up to the Session at any time. There is no need to wait on a specific session status to enqueue new events via `client.beta.sessions.events.send()`. One exception: a session paused at its budget (`stop_reason: budget_reached`) accepts only settle events -- a `user.message` there is a 400. See ? Reaching a session budget.

Interrupt

A `user.interrupt` event **jumps the queue** (ahead of any pending user messages) and forces the session into `idle`. Exception: while the session is paused at its budget, an interrupt is accepted and ignored -- it is never persisted and changes nothing (? Reaching a session budget). Use this for "stop" / "nevermind" / "cancel" commands:

```ts
await client.beta.sessions.events.send(sessionId, {
  events: [{ type: 'user.interrupt' }],
});
```

The agent stops mid-task. It does not see the interrupt as a message -- it just halts. Send a follow-up `user` event to explain what to do instead. If an outcome is active, the interrupt also marks `span.outcome_evaluation_end.result: "interrupted"` (see `shared/managed-agents-outcomes.md`) -- though not at a budget pause, where the interrupt is accepted and ignored (see ? Reaching a session budget).

The interrupted turn ends with `stop_reason: end_turn` -- the same value a turn that finishes on its own carries. There is no interruption-specific stop reason, so a drain loop can't distinguish the two from `stop_reason` alone; track that you sent the interrupt.

In a multiagent session, omitting `session_thread_id` interrupts every non-archived thread, including the primary -- it is not primary-only. Pass `session_thread_id` to stop one thread. See `shared/managed-agents-multiagent.md`.

> **Note**: Interrupt events may have empty IDs in the current implementation. When troubleshooting, use the `processed_at` timestamp along with surrounding event IDs. (Not applicable to an interrupt sent at the budget cap -- that event is never persisted, so there is nothing to locate.)

Reaching a session budget

```
A session created with a budget (see `shared/managed-agents-core.md` ? Session budgets) pauses instead of
overspending. Before every model request the platform checks whether consumed list cost has reached the cap
and pauses the thread if it has, and the session goes idle with `stop_reason: budget_reached` rather than
terminating. On the stream, the pause arrives as three events, in order:

1. `session.thread_status_idle` with `stop_reason: budget_reached`, for each thread as it pauses. When a
thread's final request both crosses the cap and finishes its turn, that thread reports `stop_reason:
end_turn` while the session still reports `budget_reached` -- key on the **session-level** `stop_reason`, not
thread-level ones, to detect the pause.
2. `session.usage` -- a snapshot of the session's cumulative usage and tracked list cost.
3. `session.status_idle` with `stop_reason: budget_reached`. The `session.usage` event always immediately
precedes this idle.

While at the cap the session accepts **only settle events** (`user.tool_confirmation`, `user.tool_result`,
`user.custom_tool_result`, `user.interrupt`); anything that starts new work, including `user.message`, is a
400 naming that list. A `user.interrupt` sent while the session is paused at its budget (all threads paused
at the cap) is accepted and ignored: it does not appear in the event list and changes nothing. Raise or
remove the budget to continue. When one thread waits on a tool ask and another is paused at the cap, the
session-level `stop_reason` is `requires_action`, not `budget_reached` -- settling the ask doesn't trigger a
model request, so respond as usual.

**No event resumes a session paused at its cap.** Update the session's budget instead: change it to a value
above the consumed list cost (higher or lower than the old cap), or remove it with `"budget": null`. An
accepted update resumes the paused work automatically.

**`session.usage`** carries the session's cumulative token totals, `list_cost` (`{amount, currency}`, rounded
to the nearest cent), `active_seconds` (concurrent-thread overlap counted once -- the figure runtime cost is
priced on), `server_tool_use` counts (`web_search_requests`, and `web_fetch_requests` -- informational,
currently always 0 since web fetch is not metered), and an echo of the session's `budget` when one is set. It
appears in the events list and the session stream -- a stream reader sees the final cost of the work that hit
the cap without an extra fetch; child threads' own streams do not carry it. The same totals live on the
session object's `usage` field, and each thread's own `usage` carries per-thread `list_cost` and
`active_seconds` -- but per-thread costs do **not** sum to the session total: the session figure additionally
includes session running time and each figure is rounded independently, so the session figure is the
authoritative one. To enforce a spend limit, set a budget rather than polling usage and interrupting the
session yourself -- the platform's gate runs before each model request.

### Event payloads

some events carry useful metadata beyond the status change itself:

`session.status_idle` -- includes a `stop_reason` field which elaborates on why the session stopped and what
type of further action is required by the user.
```json
{
  "id": "sevt_456",
  "processed_at": "2026-04-07T04:27:43.197Z",
  "stop_reason": {
    "event_ids": [
      "sevt_123"
    ],
    "type": "requires_action"
  },
  "type": "status_idle"
}
```

`span.model_request_end` contains a `model_usage` field for cost tracking and efficiency analysis:

```json
{
  "type": "span.model_request_end",
  "id": "sevt_456",
  "is_error": false,
  "model_request_start_id": "sevt_123",
  "model_usage": {
    "cache_creation_input_tokens": 0,
    "cache_read_input_tokens": 6656,
    "input_tokens": 3571,
    "output_tokens": 727
```
```

```
  },
  "processed_at": "2026-04-07T04:11:32.189Z"
}
```

`agent.thread_context_compacted` -- emitted when the conversation history was summarized to fit context. Includes `pre_compaction_tokens` so you know how much was squeezed:

```json
{
  "id": "sevt_abc123",
  "processed_at": "2026-03-24T14:05:15.787Z",
  "type": "agent.thread_context_compacted"
}
```

Archive

When done with a session, archive it to free resources:

```ts
await client.beta.sessions.archive(sessionId);
```

> Archiving a **session** is routine cleanup -- sessions are per-run and disposable. **Do not generalize this to agents or environments**: those are persistent, reusable resources, and archiving them is permanent (no unarchive; new sessions cannot reference them). See `shared/managed-agents-overview.md` -> Common Pitfalls.
</doc>

<doc path="shared/managed-agents-memory.md">
Managed Agents -- Memory Stores

> **Public beta.** Memory stores ship under the `managed-agents-2026-04-01` beta header; the SDK sets it automatically on all `client.beta.memory_stores.*` calls. If `client.beta.memory_stores` is missing, upgrade to the latest SDK release.

Sessions are ephemeral by default -- when one ends, anything the agent learned is gone. A **memory store** is a workspace-scoped collection of small text documents that persists across sessions. When a store is attached to a session (via `resources[]`), it is mounted into the container as a filesystem directory; the agent reads and writes it with the ordinary file tools, and a system-prompt note tells it the mount is there.

Every mutation to a memory produces an immutable **memory version** (`memver_...`), giving you an audit trail and point-in-time rollback/redact.

> ?? **Never store credentials, API keys, or tokens in memory stores.** Memories persist across sessions and are returned verbatim into future contexts -- a key written once is replayed into every later session that mounts the store. Use vault `environment_variable` credentials instead (`shared/managed-agents-tools.md` -> Vaults). If a secret has already been written, delete the memory and redact the affected versions (see "Redact a version" below).

Object model

Object	ID prefix	Scope	Notes
Memory store	`memstore_...`	Workspace	Attach to sessions via `resources[]`
Memory	`mem_...`	Store	One text file, addressed by `path` (<= 100KB each -- prefer many small files)
Memory version	`memver_...`	Memory	Immutable snapshot per mutation; `operation` ? `created` / `modified` / `deleted`

Create a store

`description` is passed to the agent so it knows what the store contains -- write it for the model, not for humans.

```python
store = client.beta.memory_stores.create(
    name="User Preferences",
    description="Per-user preferences and project context.",
)
print(store.id)  # memstore_01Hx...
```

```

Other SDKs: TypeScript `client.beta.memoryStores.create({...})`; Go `client.Beta.MemoryStores.New(ctx, ...)`.
See `shared/managed-agents-api-reference.md` -> SDK Method Reference for the full per-language table.

Stores support `retrieve` / `update` / `list` (with `include_archived`, `created_at_{gte,lte}` filters) /
`delete` / **`archive`**. Archive makes the store read-only -- existing session attachments continue, new
sessions cannot reference it; no unarchive.

### Seed with content (optional)

Pre-load reference material before any session runs. `memories.create` creates a memory at the given `path`;
if a memory already exists there the call returns `409` (`memory_path_conflict_error`, with the
`conflicting_memory_id`). The store ID is the first positional argument.

```python
client.beta.memory_stores.memories.create(
    store.id,
    path="/formatting_standards.md",
    content="All reports use GAAP formatting. Dates are ISO-8601...",
)
```

Attach to a session

Memory stores go in the session's `resources[]` array alongside `file` and `github_repository` resources (see
`shared/managed-agents-environments.md` -> Resources). Memory stores attach at **session create time only**
-- `sessions.resources.add()` does not accept `memory_store`.

```python
session = client.beta.sessions.create(
    agent=agent.id,
    environment_id=environment.id,
    resources=[
        {
            "type": "memory_store",
            "memory_store_id": store.id,
            "access": "read_write",  # or "read_only"; default is "read_write"
            "instructions": "User preferences and project context. Check before starting any task.",
        }
    ],
)
```

Field	Required	Notes
`type`	?	`"memory_store"`
`memory_store_id`	?	`memstore_...`
`access`	--	`"read_write"` (default) or `"read_only"` -- enforced at the filesystem level on the mount
`instructions`	--	Session-specific guidance for this store, in addition to the store's
`name`/`description`. <= 4,096 chars.

Max 8 memory stores per session. Attach multiple when different slices of memory have different owners or
lifecycles -- e.g. one read-only shared-reference store plus one read-write per-user store, or one store per
end-user/team/project sharing a single agent config.

How the agent sees it (FUSE mount)

Each attached store is mounted in the session container at `/mnt/memory/<store-name>/`. The agent interacts
with it using the standard file tools (`bash`, `read`, `write`, `edit`, `glob`, `grep`) -- there are no
dedicated memory tools. `access: "read_only"` makes the mount read-only at the filesystem level;
`"read_write"` allows the agent to create, edit, and delete files under it. A short description of each mount
(name, path, `instructions`, access) is automatically injected into the system prompt so the agent knows the
store exists without you having to mention it.

Writes the agent makes under the mount are persisted back to the store and produce memory versions just like
host-side `memories.update` calls.

Manage memories directly (host-side)
```

````
Use these for review workflows, correcting bad memories, or seeding stores out-of-band.

### List

Returns `Memory | MemoryPrefix` entries -- a `MemoryPrefix` (`type: "memory_prefix"`, just a `path`) is a
directory-like node when listing hierarchically. Use `path_prefix` to scope (include a trailing slash:
`"/notes/"` matches `/notes/a.md` but not `/notes_backup/old.md`) and `depth` to bound the tree walk. Pass
`view="full"` to include `content` in each item; the default `"basic"` returns metadata only.

```python
for m in client.beta.memory_stores.memories.list(store.id, path_prefix="/"):
    if m.type == "memory":
        print(f"{m.path}  ({m.content_size_bytes} bytes, sha={m.content_sha256[:8]})")
    else:  # "memory_prefix"
        print(f"{m.path}/")
```

### Read

```python
mem = client.beta.memory_stores.memories.retrieve(memory_id, memory_store_id=store.id)
print(mem.content)
```

`retrieve` defaults to `view="full"` (content included); `view` matters mainly on list endpoints.

### Create vs. update

| Operation | Addressed by | Semantics |
| --- | --- | --- |
| `memories.create(store_id, path=..., content=...)` | **Path** | Create at `path`. `409`
(`memory_path_conflict_error`, includes `conflicting_memory_id`) if the path is already occupied. |
| `memories.update(mem_id, memory_store_id=..., path=..., content=...)` | **`mem_...` ID** | Mutate existing
memory. Change `content`, `path` (rename), or both. Renaming onto an occupied path returns the same `409
memory_path_conflict_error`. |

```python
mem = client.beta.memory_stores.memories.create(
    store.id,
    path="/preferences/formatting.md",
    content="Always use tabs, not spaces.",
)

client.beta.memory_stores.memories.update(
    mem.id,
    memory_store_id=store.id,
    path="/archive/2026_q1_formatting.md",  # rename
)
```

### Optimistic concurrency (precondition on `update`)

`memories.update` accepts a `precondition` so you can read -> modify -> write back without clobbering a
concurrent writer. The only supported type is `content_sha256`. On mismatch the API returns `409`
(`memory_precondition_failed_error`) -- re-read and retry against fresh state.

```python
client.beta.memory_stores.memories.update(
    mem.id,
    memory_store_id=store.id,
    content="CORRECTED: Always use 2-space indentation.",
    precondition={"type": "content_sha256", "content_sha256": mem.content_sha256},
)
```

### Delete

```python
client.beta.memory_stores.memories.delete(mem.id, memory_store_id=store.id)
```
````

````
Pass `expected_content_sha256` for a conditional delete.

## Audit and rollback -- memory versions

Every mutation creates an immutable `memver_...` snapshot. Versions accumulate for the lifetime of the parent
memory; `memories.retrieve` always returns the current head, the version endpoints give you history.

| Operation that triggers it | `operation` field on the version |
| --- | --- |
| `memories.create` at a new path | `"created"` |
| `memories.update` changing `content`, `path`, or both (or an agent-side write to the mount) | `"modified"` |
| `memories.delete` | `"deleted"` |

Each version also records `created_by` -- an actor object with `type` ? `session_actor` / `api_actor` /
`user_actor` -- and, after redaction, `redacted_at` + `redacted_by`.

### List versions

Newest-first, paginated. Filter by `memory_id`, `operation`, `session_id`, `api_key_id`, or `created_at_gte`
/ `created_at_lte`. Pass `view="full"` to include `content`; default is metadata-only.

```python
for v in client.beta.memory_stores.memory_versions.list(store.id, memory_id=mem.id):
    print(f"{v.id}: {v.operation}")
```

### Retrieve a version

```python
version = client.beta.memory_stores.memory_versions.retrieve(
    version_id, memory_store_id=store.id
)
print(version.content)
```

### Redact a version

Scrubs content from a historical version while preserving the audit trail (actor + timestamps). Clears
`content`, `content_sha256`, `content_size_bytes`, and `path`; everything else stays. Use for leaked secrets,
PII, or user-deletion requests.

```python
client.beta.memory_stores.memory_versions.redact(version_id, memory_store_id=store.id)
```

## Endpoint reference

See `shared/managed-agents-api-reference.md` -> Memory Stores / Memories / Memory Versions for the full HTTP
method/path tables. Raw HTTP base path:

```
POST   /v1/memory_stores
POST   /v1/memory_stores/{memory_store_id}/archive
GET    /v1/memory_stores/{memory_store_id}/memories
PATCH  /v1/memory_stores/{memory_store_id}/memories/{memory_id}
GET    /v1/memory_stores/{memory_store_id}/memory_versions
POST   /v1/memory_stores/{memory_store_id}/memory_versions/{version_id}/redact
```

For cURL examples and the CLI (`ant beta:memory-stores ...`), WebFetch the Memory URL in
`shared/live-sources.md` -> Managed Agents.

<doc path="shared/managed-agents-multiagent.md">
# Managed Agents -- Multiagent Sessions

A coordinator agent can delegate to other agents within one session. All agents **share the container and
filesystem**; each runs in its own **thread** -- a context-isolated event stream with its own conversation
history, model, system prompt, tools, MCP servers, and skills (from that agent's own config). Threads are
````

````
persistent: the coordinator can send a follow-up to a subagent it called earlier and that subagent retains
its prior turns.

The SDK sets the `managed-agents-2026-04-01` beta header automatically on all
`client.beta.{agents,sessions}.*` calls; no additional header is required for multiagent.

---

## When to use it -- start with `self`, then add cheaper workers

**If the agent's work splits into independent pieces** -- several sources to research, many files or records
to process, anything shaped like "look into N things, then summarize" -- or one piece would fill its context
with reading, **use a multiagent session instead of one long single-threaded loop.** Each delegated piece
runs in its own thread with a fresh context window, threads run in parallel in the same container, and only
each subagent's report comes back, so the coordinator's context stays small. There is no orchestration code
to write: the coordinator is given delegation tools automatically and decides when to use them, and your
client still creates one session and reads one stream.

**Step 1 -- the smallest useful roster is the agent itself.** Add a `multiagent` block whose only entry is
`{"type": "self"}`. The coordinator can then hand self-contained sub-tasks to copies of itself -- same model,
system prompt, and tools, minus the ability to delegate further -- and combine what they report. Nothing else
changes.

```python
agent = client.beta.agents.create(
    name="Research assistant",
    description="Researches a question end to end. A copy can be spawned to own one well-scoped
sub-question.",
    model="claude-opus-5",
    system="You are a research assistant. When a request splits into independent sub-questions, delegate each
to a copy of yourself, one self-contained task per copy, then verify and combine their reports.",
    tools=[{"type": "agent_toolset_20260401"}],
    multiagent={"type": "coordinator", "agents": [{"type": "self"}]},  # the only change vs. a single agent
)

session = client.beta.sessions.create(agent=agent.id, environment_id=env.id)  # unchanged
```

**Step 2 -- move the reading-heavy work to a cheaper model.** Delegated research work is mostly searching,
reading, and extracting: many input tokens, little hard reasoning. Create a second agent on a smaller model
with a narrow `system` prompt and only the tools it needs, and list it next to `self`. A roster entry is only
a reference: the worker runs on its own `model`, `system`, and `tools`, and its tokens are billed at its own
model's rates. The large model spends its tokens on planning, checking, and synthesis; the small model does
the bulk reading.

```python
worker = client.beta.agents.create(
    name="Web researcher",
    description="Fast, low-cost, read-only researcher. Give it one well-scoped question; it searches, reads,
and reports findings with sources.",
    model="claude-haiku-4-5",
    system="Answer exactly the question you are given. Search and read as much as you need, then report
concise findings with a source URL or file path for every claim.",
    tools=[{
        "type": "agent_toolset_20260401",
        "default_config": {"enabled": False},
        "configs": [{"name": n, "enabled": True} for n in ("read", "glob", "grep", "web_fetch",
"web_search")],
    }],
)

lead = client.beta.agents.create(
    name="Research lead",
    description="Plans and synthesizes research. A copy can be spawned to own one large sub-analysis.",
    model="claude-opus-5",
    system="Plan the work. Delegate each independent, reading-heavy question to Web researcher, one
self-contained task per spawn, several in parallel. Keep verification and the final synthesis for yourself;
spawn a copy of yourself only for a sub-analysis that needs your full capability.",
    tools=[{"type": "agent_toolset_20260401"}],
    multiagent={"type": "coordinator", "agents": [worker.id, {"type": "self"}]},
````
````

```
)
```

Step 3 -- add dedicated specialists. When the sub-tasks call for different skills, give each its own agent -- its own model, a narrow `system` prompt, and only the tools it needs -- and roster them by ID next to `self`. Here the lead makes a change itself, sends the same review brief to several read-only reviewer threads for independent passes (one rostered agent can be spawned many times), and hands a test writer a self-contained brief; it then de-duplicates the findings, checks each against the code, and keeps the fix and the summary for itself.

```python
reviewer = client.beta.agents.create(
    name="Concurrency reviewer",
    description="Read-only reviewer for race conditions, deadlocks, lost updates, and retry/idempotency bugs. Give it the changed file paths and the invariants that must hold; it reports findings with file:line evidence. Spawn several on the same change for independent reviews.",
    model="claude-sonnet-5",
    system="Review only the files you are pointed at. Look for concurrency bugs: unsynchronized shared state, lock ordering, non-atomic read-modify-write, retries without idempotency. Report each finding as file:line, the interleaving that triggers it, and a suggested fix; say plainly if you found none.",
    tools=[{"type": "agent_toolset_20260401", "default_config": {"enabled": False},
            "configs": [{"name": n, "enabled": True} for n in ("read", "glob", "grep")]}],
)
test_writer = client.beta.agents.create(
    name="Test writer",
    description="Writes and runs tests. Give it the module path, the behavior to pin down, and the test command; it adds test files, runs them, and reports results with output.",
    model="claude-sonnet-5",
    system="Write focused tests for the behavior you are given, run them with the command you are given, and report pass/fail, the relevant output, and the paths of files you added. Do not edit non-test code; if the code under test looks wrong, report that instead.",
    tools=[{"type": "agent_toolset_20260401", "default_config": {"enabled": True},
            "configs": [{"name": n, "enabled": False} for n in ("web_fetch", "web_search")]}],
)
lead = client.beta.agents.create(
    name="Engineering lead",
    description="Plans and makes code changes and integrates specialist reports. A copy can be spawned to own one independent change.",
    model="claude-opus-5",
    system="Make the change yourself. Then, in parallel, send the changed paths and invariants to three Concurrency reviewers and the module path and test command to Test writer. Merge and de-duplicate the reviewers' findings, check each against the code before acting on it, fix, and have Test writer re-run. Keep design decisions and the final summary for yourself.",
    tools=[{"type": "agent_toolset_20260401"}],
    multiagent={"type": "coordinator", "agents": [reviewer.id, test_writer.id, {"type": "self"}]},
)
```

The same shape fits a pipeline of different specialists: a fast document extractor (for example on Claude Haiku 4.5) that writes one JSON file per input document, a verifier that checks each file against its source, and a lead that applies the corrections and writes the final table to `/mnt/session/outputs/`. Put the input and output paths in every task: threads share the container's filesystem, not each other's conversation.

- **Good fits:** parallel research across sources; reading large amounts of material without filling the coordinator's context; specialists with narrow prompts and tool sets rather than one agent carrying every tool. **Poor fit:** a small single-step task -- every delegation costs a round-trip and a re-briefing.
- **Write `name` and `description` for the coordinator to read.** The coordinator chooses whom to spawn from each roster entry's name and description (the `self` entry is listed under the coordinator's own name), so say what each agent is good at and what to hand it. Names must be unique across the roster; don't name an agent `self`.
- **Say how to delegate in the coordinator's `system` prompt** -- what to hand off and to whom, how many at once, what to keep for itself, and what is too small to be worth delegating (the *Delegating to subagents* sample prompt in `shared/model-migration.md` is a starting point). Subagents see none of the coordinator's conversation, so each task must carry the paths, constraints, and report format it needs. Spawning returns immediately; the subagent's report arrives in a later coordinator turn.
- **Limits:** 1-20 roster entries (at most one `self`; each rostered agent can be spawned many times), one level of delegation (a roster member must not have its own `multiagent`), and at most 25 concurrent threads per session -- archive finished threads if a long session needs more (see *Interrupting and archiving threads* below).

The sections below are the reference for rosters, threads, events, and client-side handling; the platform guide is `https://platform.claude.com/docs/en/managed-agents/multiagent-orchestration.md`.

Declare the roster on the coordinator

`multiagent` is a **top-level field** on `agents.create()` / `agents.update()` -- **not** a `tools[]` entry. `agents` lists 1-20 roster entries. Nothing changes on `sessions.create()` -- the roster is resolved from the coordinator's config.

```python
orchestrator = client.beta.agents.create(
    name="Engineering lead",
    model="claude-opus-5",
    system="You coordinate engineering work. Delegate code review to the reviewer and test writing to the test agent.",
    tools=[{"type": "agent_toolset_20260401"}],
    multiagent={
        "type": "coordinator",
        "agents": [
            reviewer.id,                                          # bare string -- latest version
            {"type": "agent", "id": test_writer.id, "version": 4},  # pinned version
            {"type": "self"},                                     # the coordinator itself
        ],
    },
)

session = client.beta.sessions.create(agent=orchestrator.id, environment_id=env.id)
```

Roster entry	Shape	Notes
String shorthand	`"agent_abc123"`	References the latest version of a stored agent.
Agent reference	`{type: "agent", id, version?}`	Omit `version` to pin the latest at coordinator save time.
Self	`{type: "self"}`	The coordinator can spawn copies of itself.
Advisor	`{type: "advisor", model}`	A model the session's primary thread can consult mid-turn. At most one per roster. See ? Advisor below.

If the session was created with `agent_with_overrides` (see `shared/managed-agents-core.md` -> Override agent configuration for a session), those overrides apply to the **coordinator and its `self` copies**. Roster agents referenced by ID always use their own as-created configuration -- overrides do not propagate to them.

The coordinator's thread receives delegation tools for working the roster: `list_agents` (see the roster) and `send_to_agent` (task or message a member). Up to **20 unique agents** in the roster; the coordinator may spawn **multiple copies** of each. **One level of delegation only** -- and it is enforced rather than silently flattened: rostering an agent that itself carries a `multiagent.agents` roster fails the create or update with a validation error.

Inference geo pins must be roster-uniform. When agents pin an inference geography (`model.inference_geo` -- see `shared/managed-agents-core.md` ? Pinning inference geography), the coordinator's pin and every roster member's must all be the same value or all be unset. A mismatched roster is a 400 validation error, both when the agent is saved and when a session-create `model` override changes any of the pins.

Threads

The session-level event stream is the **primary thread** -- it shows the coordinator's trace plus a condensed view of subagent activity (thread status transitions and cross-thread messages, not every subagent tool call). Drill into a specific subagent via the per-thread endpoints:

Operation	HTTP	SDK (`client.beta.sessions.threads.*`)
List threads	`GET /v1/sessions/{sid}/threads`	`.list(session_id)`
Retrieve one	`GET /v1/sessions/{sid}/threads/{tid}`	`.retrieve(thread_id, session_id=...)`
Archive	`POST /v1/sessions/{sid}/threads/{tid}/archive`	`.archive(thread_id, session_id=...)`
List thread events	`GET /v1/sessions/{sid}/threads/{tid}/events`	`.events.list(thread_id, session_id=...)`

| Stream thread events | `GET /v1/sessions/{sid}/threads/{tid}/stream` | `.events.stream(thread_id, session_id=...)` |

Each `SessionThread` carries `id`, `status` (`running` | `idle` | `rescheduling` | `terminated`), `agent` (a resolved snapshot of the agent config -- `id`, `name`, `model`, `system`, `tools`, `skills`, `mcp_servers`, `version` -- except advisor threads, whose `agent` is the two-field advisor form `{"type": "advisor", "model": ...}` -- see ? Advisor), `parent_thread_id` (null for the primary thread, which is included in the list), `archived_at`, and optional `stats`/`usage`. Per-thread `usage.list_cost` figures do **not** sum to the session total -- the session figure additionally includes session running time and each figure is rounded independently; the session-level `usage.list_cost` is authoritative. **Session status aggregates thread statuses** -- if any thread is `running`, `session.status` is `running`. Max **25 concurrent threads** (advisor threads are exempt -- see ? Advisor). When draining a per-thread stream, break on `session.thread_status_idle` (and check its `stop_reason` as you would for the session-level idle).

A session budget is one shared cap across all threads -- no per-thread caps. Each thread's consumption is priced at its own served model, and threads pause independently (`stop_reason: budget_reached`) as the shared cap is reached; one thread can pause while another finishes its in-flight request. A thread waiting on `requires_action` outranks the cap at the session level. See `shared/managed-agents-core.md` ? Session budgets.

Multiagent events (on the session stream)

Event	Payload highlights	Meaning
`session.thread_created`	`session_thread_id`, `agent_name`	A new thread was created.
`session.thread_status_running`	`session_thread_id`, `agent_name`	Thread started activity.
`session.thread_status_idle`	`session_thread_id`, `agent_name`, **`stop_reason`**	Thread is awaiting input -- or paused at the session's shared budget (`stop_reason: budget_reached`). Inspect `stop_reason` (same shape as `session.status_idle.stop_reason`).
`session.thread_status_rescheduled`	`session_thread_id`, `agent_name`	Thread is rescheduling after a retryable error.
`session.thread_status_terminated`	`session_thread_id`, `agent_name`	Thread ended -- completed its work and self-terminated (advisor consultation threads -- see ? Advisor), was archived, or hit a terminal error.
`agent.thread_message_sent`	`to_session_thread_id`, `to_agent_name`, `content`	*This* thread sent a message to another thread. On the primary stream: the coordinator sent a task or follow-up to an agent.
`agent.thread_message_received`	`from_session_thread_id`, `from_agent_name`, `content`	A message arrived on *this* thread from another. On the primary stream: an agent sent a report or question to the coordinator.

> **Direction is relative to the thread whose stream carries the event**, not to the coordinator. The same delegated task is an `agent.thread_message_sent` on the primary stream and an `agent.thread_message_received` on the child's own stream. Reading `_received` as "a subagent finished" is wrong once you're reading a child stream.

Previewing a subagent's text

Each thread's stream accepts the same `event_deltas[]` parameter as the session-level stream, so you can watch a subagent's text as the model generates it:

```
GET /v1/sessions/{sid}/threads/{tid}/stream?event_deltas%5B%5D=agent.message
```

Previews are thread-scoped. A child's previews are delivered only on that child's stream and never cross-posted to the session-level stream, whose previews stay scoped to the primary thread. So watching a subagent live means opening its thread stream -- the session stream will not show it, no matter what you pass.

> ?? **Only plain assistant text previews.** A subagent's *reply to its coordinator* rides `agent.thread_message_sent` and is never previewed. A worker that does nothing but report back therefore streams no deltas at all, even with a correct opt-in on the right thread. To get a live preview out of a subagent, its prompt has to make it write the answer as a plain assistant message in its own thread first, and only then report to the coordinator. Run one accumulator per connection, and exit the read loop on `session.thread_status_idle`. Opt-in, accumulate, and reconcile details: `shared/managed-agents-events.md` -> Live previews.

````
## Advisor

An `{"type": "advisor", "model": "<model id>"}` roster entry gives the session's **primary thread** an
advisor: a model it can consult mid-turn for strategic guidance (planning an approach, getting unstuck,
reviewing work before finishing). The entry has exactly two fields -- `type` and `model` -- and can sit
alongside any other roster forms; a roster with no other entries works too. The advisor is also available as
a server tool on the Messages API (`advisor_20260301` -- see `shared/tool-use-concepts.md` -> Advisor); the
Managed Agents surface differs in configuration and delivery: the roster entry has **no `max_uses`,
`max_tokens`, or `caching` fields**, and advice arrives through thread events rather than
`advisor_tool_result` blocks.

```python
agent = client.beta.agents.create(
    name="Backend engineer",
    model="claude-sonnet-5",
    system="You implement backend features end to end.",
    multiagent={
        "type": "coordinator",
        "agents": [{"type": "advisor", "model": "claude-opus-5"}],
    },
)
```

(Claude Opus 5 is the default advisor choice. It is a redacted advisor -- the agent reads its advice
server-side, but the client sees `[{"type": "redacted"}]`; see *Plaintext vs redacted delivery* below. For
client-readable advice, a plaintext advisor such as `claude-opus-4-8` is valid only when the agent's own
model is `claude-opus-4-8` or below -- agents on Claude Opus 5, Claude Fable 5, or Claude Mythos 5 can only
pair with redacted advisors, so client-readable advice is not available for them (pairing table:
`shared/tool-use-concepts.md`).)

**Rules:**
- **At most one advisor entry per roster.** The entry occupies the reserved roster name `anthropic.advisor`
-- a roster that also lists a member literally named `anthropic.advisor` is a 400. In responses, the advisor
entry is echoed **last** in the roster regardless of submitted position.
- **Pairing is validated at agent save:** the advisor model must meet a minimum capability bar, and the
agent's own model must not be more capable than its advisor (equals can pair). Invalid pairing -> 400. The
valid pairs mirror the Messages advisor tool's executor<->advisor table (`shared/tool-use-concepts.md`) --
except Claude Fable 5, which is temporarily unavailable as a Managed Agents advisor; use claude-opus-5
instead. Claude Mythos 5 advisors are unaffected -- the unavailability is specific to claude-fable-5, despite
the two models' shared capabilities.
- **Only the primary thread consults it.** The advisor is not a roster agent: invisible to the coordinator's
`list_agents` tool, unreachable via `send_to_agent`, and roster agents cannot consult it.

**How consultations work.** Each consultation runs as a platform-spawned thread named `anthropic.advisor`
that terminates itself when done; the advice is delivered to the primary thread as an
`agent.thread_message_received` event. Typical event order (the reserved name rides `agent_name` on lifecycle
events and `from_agent_name` on the delivery):

1. `session.thread_created`
2. `session.thread_status_running`
3. `agent.thread_message_received` -- the advice
4. `session.thread_status_idle` (`stop_reason: end_turn`)
5. `session.thread_status_terminated`

No `agent.tool_use` and no `agent.thread_message_sent` are emitted for a consultation, and **the advice
delivery is not guaranteed to precede the advisor thread's idle/terminated events** -- don't treat those as
"advice already delivered."

**Plaintext vs redacted delivery.** Whether your client can read the advice is the advisor model's policy,
mirroring the Messages advisor tool's result variants: models that return plaintext there deliver readable
text content here; models that return redacted results deliver `[{"type": "redacted"}]` as the message
content on every client surface, while the agent still reads the full advice server-side. Advisor thinking is
never surfaced. Clients cannot send `redacted` blocks themselves -- an event containing one is a 400.

**Failure and interruption.** A failed consultation -- or one abandoned via a `user.interrupt` carrying the
advisor thread's `session_thread_id` -- never fails the agent's turn: the agent continues after a generic
notice. A session-level `user.interrupt` during a consultation halts the whole session as usual (every
thread, primary included), terminating the advisor thread with no advice delivered.
````

Threads, billing, caching. Advisor threads are **exempt from the 25-concurrent-thread limit**. They appear in the session's thread list with `agent` set to the advisor form as configured (`{"type": "advisor", "model": ...}`) and `parent_thread_id` set to the primary thread. Consultations are billed at the advisor model's rates; their tokens appear in the advisor thread's usage and the session's totals. Advisor-side prompt caching is automatic -- nothing to configure.

Removing the advisor: update the agent with a roster that omits the entry; if the advisor is the roster's only entry, clear the roster with `"multiagent": null`.

Tool permissions and custom tools from subagent threads

When a subagent needs your client (an `always_ask` confirmation, or a custom tool result), the request is **cross-posted to the primary thread** with `session_thread_id` identifying the originating thread -- so you only need to watch the session stream. Reply with `user.tool_confirmation` (carrying `tool_use_id`) or `user.custom_tool_result` (carrying `custom_tool_use_id`), and **echo the `session_thread_id` from the originating event** (the SDK param type and docstring expect it). The server also routes by the tool-use ID, so the echo is belt-and-suspenders rather than load-bearing -- but include it.

```python
for event_id in stop.event_ids:
    pending = events_by_id[event_id]
    confirmation = {
        "type": "user.tool_confirmation",
        "tool_use_id": event_id,
        "result": "allow",
    }
    if pending.session_thread_id is not None:
        confirmation["session_thread_id"] = pending.session_thread_id
    client.beta.sessions.events.send(session.id, events=[confirmation])
```

The same pattern applies to `user.custom_tool_result`.

Interrupting and archiving threads

- **`user.interrupt` without `session_thread_id` interrupts every non-archived thread in the session, including the primary** -- it is not a primary-only stop. Pass `session_thread_id` to target one thread.
- **Against a child thread blocked on `requires_action`**, the interrupt closes each pending tool call with an *error* tool result (`"Tool execution was interrupted before completion. Please retry."`) and re-emits `session.thread_status_idle` with `stop_reason: end_turn` directly -- the model is not sampled. Against a thread already `idle`, the interrupt is a no-op.
- **Archive requires the thread to be idle, and `requires_action` counts as idle** -- a thread parked on a pending tool call can be archived directly. Only a *running* thread must be interrupted first.

Pitfalls

- **Don't put the roster on `sessions.create()` or in `tools[]`.** `multiagent` is a top-level agent field; update the coordinator, then start a session that references it.
- **Don't assume shared context.** Threads share the filesystem but not conversation history or tools. If the coordinator needs a subagent to act on something, it must say so in the delegated message (or write it to disk).
- **Depth > 1 is a validation error.** Rostering an agent that itself carries a `multiagent.agents` roster fails the create or update -- only the session's coordinator delegates.

For per-language bindings beyond Python, WebFetch `https://platform.claude.com/docs/en/managed-agents/multiagent-orchestration.md` (see `shared/live-sources.md`).

<doc path="shared/managed-agents-onboarding.md">
Managed Agents -- Onboarding Flow

> **Invoked via `/claude-api managed-agents-onboard`?** You're in the right place. Run the interview below -- don't summarize it back to the user, ask the questions.

```
Claude Managed Agents is a hosted agent: Anthropic runs the agent loop and provisions a sandboxed container
per session where the agent's tools execute (or your own worker, with a `self_hosted` environment -- see
`shared/managed-agents-self-hosted-sandboxes.md`). You supply an **agent config** (tools, skills, model,
system prompt -- reusable, versioned) and an **environment config** (the sandbox -- reusable across agents).
Each run is a **session**.

The flow is four beats -- **describe -> agent -> environment -> session** -- the same arc as the Console
quickstart, and the same philosophy: **value before credentials**. The user goes from idea to a runnable
session before any auth ask; each credential is *flagged* at the moment the design makes it relevant (?2) and
*collected* once, at session setup (?4), where it binds (`sessions.create()`) and gets exercised
(smoke-test). Read `shared/managed-agents-core.md` alongside this -- it has full detail for each knob; this
doc is the interview script.

---

## 1. Describe the task

**Open with a one-breath signpost and a single open prompt -- don't guess, don't questionnaire.** In your own
words:

> Managed Agents is hosted -- Anthropic runs the agent loop, the sandbox, and the infrastructure; you just
define the agent. We'll do this in three moves: the agent, the environment it runs in, then a live test
session. So: describe the agent you want -- what should it do, and what kicks it off (a person, an event, a
schedule)?

Let them answer in full before configuring anything.

## 2. Configure the agent -- propose, don't interrogate

Their description does the interview's work. Draft the agent config from it and **present it as a proposal
with your suggestions inline** -- the user reacts to a concrete config instead of answering a question list.
At most one batched follow-up for true gaps. Suggest where the description gives you an opening:

- **Tools** -- enable the full prebuilt toolset by default (`agent_toolset_20260401`: `bash`, `read`,
`write`, `edit`, `glob`, `grep`, `web_fetch`, `web_search`). **Suggest MCP servers** for any third-party
service the job names (GitHub, Linear, Slack, ...) -- and flag the credential each one implies as you suggest
it ("Linear MCP -> you'll need a Linear API token at kickoff"), so ?4's auth step is a formality, not a
surprise. Collection itself waits for ?4. Custom tools only if the user's own app must answer calls (name,
description, input schema -- their handler code is theirs; don't generate it).
- **Skills** -- **suggest** prebuilt `xlsx`/`docx`/`pptx`/`pdf` when the job produces those artifacts; custom
by `skill_id` (max 20 total per agent, prebuilt + custom combined).
- **Outcome** -- if the description implies checkable "done" criteria (or you can elicit them in the
follow-up: not "a good report" but "a CSV with a numeric `price` column per SKU"), **suggest an Outcome
kickoff** -- the harness grades and iterates against a rubric (`shared/managed-agents-outcomes.md`).
- **On-hand resources** -- repos on disk (`github_repository`: URL, optional `mount_path`/`checkout`; token
comes in ?4), files to seed (Files API upload -> `{type: "file", file_id, mount_path}`; read-only), if the
job references them.
- **Model** -- default `claude-opus-5`; `claude-fable-5` for the hardest long-horizon work
(`shared/model-migration.md` -> Migrating to Claude Fable 5).

> ?? **PR creation needs the GitHub MCP server too** -- a `github_repository` mount is filesystem-only. Edit
in the mount -> push branch via `bash` -> open the PR via the MCP `create_pull_request` tool.

Full detail per knob: `shared/managed-agents-tools.md` (toolset, MCP, custom tools, skills),
`shared/managed-agents-environments.md` (repos, files).

## 3. Environment

Usually zero or one question:

- **Reuse or create?** Environments are shared across agents -- check for an existing one first.
- **Networking** -- default unrestricted egress. Switch to `limited` only if the user wants egress control --
then set `allow_mcp_servers: true` or list every MCP server domain in `allowed_hosts`, or those tools fail
silently.
- **Suggest `self_hosted`** when the signals are there: tools must run on their own infra, secrets can't
leave it, or they need binaries/data the cloud container won't have
(`shared/managed-agents-self-hosted-sandboxes.md`; not available on Claude Platform on AWS). Otherwise
`cloud` -- don't raise it unprompted for simple jobs.
```

```
## 4. Session -- auth, then test run

**Auth happens here -- collect the credentials flagged in ?2, now that the config is settled:** a vault
(existing or `vaults.create()`) + `vaults.credentials.create()` for each MCP server declared in ?2,
`environment_variable` credentials for API keys the job uses (substituted at egress; the sandbox sees a
placeholder), and the `authorization_token` for each repo mount. Credentials are write-only; MCP credentials
match servers by URL and auto-refresh. See `shared/managed-agents-tools.md` -> Vaults.

**Silent viability gate -- run this yourself before emitting anything; surface only the gaps.** Walk the job
clause by clause: every verb maps to an enabled tool or MCP server ("open a PR" -> GitHub MCP, not just the
mount); every MCP server and repo mount has its credential from the auth step; every external host is
reachable under the networking choice; every file/repo/dataset the job references is mounted; "done" is
checkable. If something's missing, say so and resolve it -- don't emit a config you already know is
under-resourced.

**Kickoff -- pick one, never both:**
- `user.message` -- conversational.
- `user.define_outcome` + rubric -- when ?2 settled on an Outcome; the harness iterates and grades until the
rubric passes.
- **Scheduled shape?** Skip per-session kickoff entirely -- create a **deployment** (`deployments.create()`
with `schedule` + `initial_events`); each firing creates the session autonomously. See
`shared/managed-agents-scheduled-deployments.md`.

Mechanics to bake into the runtime code: session creation resolves resources (a bad mount surfaces there,
before tokens) but does not itself provision the sandbox; open the event stream *before* sending the kickoff;
break on `session.status_terminated`, or `session.status_idle` with any non-`requires_action` `stop_reason`
-- terminal, or `budget_reached`, which is not terminal (only a budget change/removal resumes it)
(`shared/managed-agents-client-patterns.md` Pattern 5); usage lands on `span.model_request_end`; artifacts
land in `/mnt/session/outputs/` (`files.list({scope_id: session.id, ...})`).

## 5. Integrate -- emit the code

Go straight from the last answer to the code -- no preamble, no lecture about setup-vs-runtime; the two-block
structure shows it. Generate **two clearly-separated blocks**:

**Block 1 -- Setup (run once, store the IDs).** Prefer **YAML files + `ant` CLI** -- agents and environments
are version-controlled definitions users should check in and apply from CI:

1. `<name>.agent.yaml` (flat: `name`, `model`, `system`, `tools`, `mcp_servers`, `skills`) and
`<name>.environment.yaml`
2. ```sh
   AGENT_ID=$(ant beta:agents create < <name>.agent.yaml --transform id -r)
   ENV_ID=$(ant beta:environments create < <name>.environment.yaml --transform id -r)
   # CI sync: ant beta:agents update --agent-id "$AGENT_ID" --version N < <name>.agent.yaml
   ```

SDK fallback if the user asks -- and **required on Claude Platform on AWS**, where auth is SigV4 and the
`ant` CLI has no SigV4 mode (use the platform client from `shared/claude-platform-on-aws.md`): label it `#
ONE-TIME SETUP -- run once, save the IDs` and call `environments.create()` -> `agents.create()`.

> ?? **Deployments are newer than the rest of the MA surface.** Before emitting `ant beta:deployments ...` or
`client.beta.deployments` / `client.beta.deployment_runs` calls, verify the user's installed CLI/SDK exposes
them (`ant beta:deployments --help`; `hasattr(client.beta, "deployments")`). If not, emit raw HTTP against
`POST /v1/deployments` with the `managed-agents-2026-04-01` beta header (plus `oauth-2025-04-20` when
authenticating with a Bearer token from `ant auth print-credentials`), and leave an upgrade note marking what
simplifies to SDK calls.

Scheduled shape? The deployment is setup, not runtime. Create it in Block 1, after the agent/environment
IDs exist (`deployments.create()` with `schedule` + `initial_events`). Block 2 is then **not** a session loop
-- there is no per-run kickoff to send. Emit instead: a manual-run trigger (`POST /v1/deployments/{id}/run`)
so the user can test now rather than wait for the first firing -- the manual run doubles as the smoke test --
plus a fetch helper (latest `deployment_runs` entry -> `session_id` -> Console URL +
`files.list(scope_id=session_id)` for the artifacts).

Block 2 -- Runtime (every invocation; conversational and Outcome shapes). SDK code in the detected
language (Python/TS/cURL -- SKILL.md -> Language Detection); don't emit shell loops here:

1. Load `agent_id` + `env_id` from config/env
2. `sessions.create(agent=AGENT_ID, environment_id=ENV_ID, resources=[...], vault_ids=[...])`, then print the
Console URL so the user can watch live:
```
```

`https://platform.claude.com/workspaces/default/sessions/{session.id}` (swap `default` for their workspace slug)
3. **Smoke-test when the job depends on MCP servers, credentials, or locked-down hosts** -- those failures don't surface at `sessions.create()`, only on first use. One cheap probe turn ("Confirm you can reach <service> and list 1-2 items; don't start the task"), verify, then send the real kickoff. Skip when there are no external dependencies.
4. Open stream -> send the ?4 kickoff -> loop with the terminal gate from ?4.

> ?? **Never emit `agents.create()` and `sessions.create()` in the same unguarded block** -- that teaches creating a new agent per run, the #1 anti-pattern. Single-script requests: wrap creation in `if not os.getenv("AGENT_ID"):`.

Pull exact syntax from `{lang}/managed-agents/README.md` for your detected language (cURL and C#: use `curl/managed-agents.md` as the wire-level reference). Don't invent field names.
</doc>

<doc path="shared/managed-agents-outcomes.md">
Managed Agents -- Outcomes

An **outcome** elevates a session from *conversation* to *work*: you state what "done" looks like, and the harness runs an iterate -> grade -> revise loop until the artifact meets the rubric, hits `max_iterations`, or is interrupted. A separate **grader** (independent context window) scores each iteration against your rubric and feeds per-criterion gaps back to the agent.

The SDK sets the `managed-agents-2026-04-01` beta header automatically on all `client.beta.sessions.*` calls; no additional header is required for outcomes.

The `user.define_outcome` event

Outcomes are not a field on `sessions.create()`. You create a normal session, then send a `user.define_outcome` event. The agent starts working on receipt -- **do not also send a `user.message`** to kick it off.

You can collapse both calls into one by passing a single `user.define_outcome` in the session's `initial_events` array -- same event, same rules, one round trip (see `shared/managed-agents-core.md` -> Seeding a session with `initial_events`). More than one `user.define_outcome` in that array, or one without a `rubric`, rejects the whole create with a 400.

```python
session = client.beta.sessions.create(
    agent=AGENT_ID,
    environment_id=ENVIRONMENT_ID,
    title="Financial analysis on Costco",
)

client.beta.sessions.events.send(
    session_id=session.id,
    events=[
        {
            "type": "user.define_outcome",
            "description": "Build a DCF model for Costco in .xlsx",
            "rubric": {"type": "text", "content": RUBRIC_MD},
            # or: "rubric": {"type": "file", "file_id": rubric.id}
            "max_iterations": 5,  # optional; default 3, max 20
        }
    ],
)
```

Field	Type	Notes
`type`	`"user.define_outcome"`	
`description`	string	The task. This is what the agent works toward -- no separate `user.message` needed.
`rubric`	`{type: "text", content}` | `{type: "file", file_id}`	**Required.** Markdown with explicit, independently gradeable criteria. Upload once via `client.beta.files.upload(...)` (beta `files-api-2025-04-14`) to reuse across sessions.
`max_iterations`	int	Optional. Default **3**, max **20**.

````
The event is echoed back on the stream with a server-assigned `outcome_id` and `processed_at`.

> **Writing rubrics.** Use explicit, gradeable criteria ("CSV has a numeric `price` column"), not vibes
("data looks good") -- the grader scores each criterion independently, so vague criteria produce noisy loops.
If you don't have a rubric, have Claude analyze a known-good artifact and turn that analysis into one.

---

## Outcome-specific events

These appear on the standard event stream (`sessions.events.stream` / `.list`) alongside the usual `agent.*`
/ `session.*` events.

| Event | Payload highlights | Meaning |
|---|---|---|
| `span.outcome_evaluation_start` | `outcome_id`, `iteration` (0-indexed) | Grader began scoring iteration
*N*. |
| `span.outcome_evaluation_ongoing` | `outcome_id` | Heartbeat while the grader runs. Grader reasoning is
opaque -- you see *that* it's working, not *what* it's thinking. |
| `span.outcome_evaluation_end` | `outcome_evaluation_start_id`, `outcome_id`, `iteration`, `result`,
`explanation`, `usage` | Grader finished one iteration. `result` drives what happens next (table below). |

### `span.outcome_evaluation_end.result`

| `result` | Next |
|---|---|
| `satisfied` | Session -> `idle`. Terminal for this outcome. |
| `needs_revision` | Agent starts another iteration. |
| `max_iterations_reached` | No further grader cycles. Agent may run one final revision, then session ->
`idle`. |
| `failed` | Session -> `idle`. Rubric fundamentally doesn't match the task (e.g. description and rubric
contradict). |
| `interrupted` | Emitted whenever a `user.interrupt` arrives while an outcome is active -- **even if
evaluation hadn't started**. In that case `outcome_evaluation_start_id` is an empty string rather than an
event ID, so don't use it as a lookup key without checking. (Except an interrupt sent while paused at the
session budget, which is accepted and ignored -- see `shared/managed-agents-events.md` ? Reaching a session
budget.) |

```json
{
  "type": "span.outcome_evaluation_end",
  "id": "sevt_01jkl...",
  "outcome_evaluation_start_id": "sevt_01def...",
  "outcome_id": "outc_01a...",
  "result": "satisfied",
  "explanation": "All 12 criteria met: revenue projections use 5 years of historical data, ...",
  "iteration": 0,
  "usage": { "input_tokens": 2400, "output_tokens": 350, "cache_creation_input_tokens": 0,
"cache_read_input_tokens": 1800 },
  "processed_at": "2026-03-25T14:03:00Z"
}
```

---

## Checking status & retrieving deliverables

**Status** -- either watch the stream for `span.outcome_evaluation_end`, or poll the session and read
`outcome_evaluations`:

```python
session = client.beta.sessions.retrieve(session.id)
for ev in session.outcome_evaluations:
    print(f"{ev.outcome_id}: {ev.result}")  # outc_01a...: satisfied
```

**Deliverables** -- the agent writes to `/mnt/session/outputs/`. Once idle, fetch via the Files API with
`scope_id=session.id`. This is the same session-outputs mechanism documented in
`shared/managed-agents-environments.md` -> Session outputs (including the dual-beta-header requirement on
````

```
`files.list`).

---

## Interaction rules & pitfalls

- **One outcome at a time.** Chain by sending the next `user.define_outcome` only after the previous one's
terminal `span.outcome_evaluation_end` (`satisfied` / `max_iterations_reached` / `failed` / `interrupted`).
The session retains history across chained outcomes.
- **Steering is allowed but optional.** You *may* send `user.message` events mid-outcome to nudge direction,
but the agent already knows to keep working until terminal -- don't send "keep going" prompts. (Exception: a
session paused at its budget (`stop_reason: budget_reached`) accepts only settle events -- a steering
`user.message`, or a chained `user.define_outcome`, is a 400 there; see `shared/managed-agents-events.md` ?
Reaching a session budget.)
- **`user.interrupt` pauses the current outcome** -- it marks `result: "interrupted"` and leaves the session
`idle`, ready for a new outcome or conversational turn. (Exception: sent while paused at the session budget,
the interrupt is accepted and ignored and the outcome stays active -- see `shared/managed-agents-events.md` ?
Reaching a session budget.)
- **After terminal, the session is reusable** -- continue conversationally or define a new outcome.
- **Outcome != session-create field.** Don't put `outcome`, `rubric`, or `description` on `sessions.create()`
-- outcomes are always sent as a `user.define_outcome` event.
- **Idle-break gate is unchanged.** In your drain loop, keep using `event.type === 'session.status_idle' &&
event.stop_reason?.type !== 'requires_action'` -- do **not** gate on `span.outcome_evaluation_end` alone (on
`needs_revision` the session keeps running). See `shared/managed-agents-client-patterns.md` Pattern 5.

For the raw HTTP shapes and per-language SDK bindings beyond Python, WebFetch
`https://platform.claude.com/docs/en/managed-agents/define-outcomes.md` (see `shared/live-sources.md`).
</doc>

<doc path="shared/managed-agents-overview.md">
# Managed Agents -- Overview

Managed Agents provisions a container per session as the agent's workspace. The agent loop runs on
Anthropic's orchestration layer; the container is where the agent's *tools* execute -- bash commands, file
operations, code. You create a persisted **Agent** config (model, system prompt, tools, MCP servers, skills),
then start **Sessions** that reference it. The session streams events back to you; you send user messages and
tool results in.

## ?? THE MANDATORY FLOW: Agent (once) -> Session (every run)

**Why agents are separate objects: versioning.** An agent is a persisted, versioned config -- every update
creates a new immutable version, and sessions pin to a version at creation time. This lets you iterate on the
agent (tweak the prompt, add a tool) without breaking sessions already running, roll back if a change
regresses, and A/B test versions side-by-side. None of that works if you `agents.create()` fresh on every run.

Every session references a pre-created `/v1/agents` object. Create the agent once, store the ID, and reuse it
across runs.

| Step | Call | Frequency |
|---|---|---|
| 1 | `POST /v1/agents` -- `model`, `system`, `tools`, `mcp_servers`, `skills` live here | **ONCE.** Store
`agent.id` **and** `agent.version`. |
| 2 | `POST /v1/sessions` -- `agent: "agent_abc123"` or `{type: "agent", id, version}` | **Every run.**
String shorthand uses latest version. |

If you're about to write `sessions.create()` with `model`, `system`, or `tools` on the session body --
**stop**. Those fields live on `agents.create()`. The session takes a *pointer* only.

**When generating code, separate setup from runtime.** `agents.create()` belongs in a setup script (or a
guarded `if agent_id is None:` block), not at the top of the hot path. If the user's code calls
`agents.create()` on every invocation, they're accumulating orphaned agents and paying the create latency for
nothing. The correct shape is: define the agent as a version-controlled YAML manifest, apply it once with
`ant beta:agents create < agent.yaml` (or a guarded setup script -- see `shared/anthropic-cli.md`), persist
the returned ID (config file, env var, secrets manager), and have every run load the ID and call
`sessions.create()`.

**To change the agent's behavior, use `POST /v1/agents/{id}` -- don't create a new one.** Each update bumps
the version; running sessions keep their pinned version, new sessions get the latest (or pin explicitly via
`{type: "agent", id, version}`). See `shared/managed-agents-core.md` -> Agents -> Versioning. To change
`tools`/`mcp_servers` on **one running session** without touching the agent object, use `sessions.update()`
```

(`vault_ids` attaches at session create only) -- see `shared/managed-agents-core.md` -> Updating the agent configuration mid-session.

Beta Headers

Managed Agents is in beta. The SDK sets required beta headers automatically:

Beta Header	What it enables
`managed-agents-2026-04-01`	Agents, Environments, Sessions, Events, Session Resources, Session Threads, Outcomes, Multiagent, Vaults, Credentials, Memory Stores, Deployments
`skills-2025-10-02`	Skills API (for managing custom skill definitions)
`files-api-2025-04-14`	Files API for file uploads

Which beta header goes where: The SDK sets `managed-agents-2026-04-01` automatically on `client.beta.{agents,environments,sessions,vaults,memory_stores,deployments,deployment_runs}.*` calls, and `files-api-2025-04-14` / `skills-2025-10-02` automatically on `client.beta.files.*` / `client.beta.skills.*` calls. You do NOT need to add the Skills or Files beta header when calling Managed Agents endpoints. On raw HTTP the Managed Agents header **grants Files API access on its own**, so uploading a file for use as a session resource does not need `files-api-2025-04-14` alongside it. (Direct Skills API calls over cURL do still need `skills-2025-10-02`; the `ant` CLI and the SDKs send it for you.) **Exception -- session-scoped file listing:** `client.beta.files.list({scope_id: session.id})` is a Files endpoint that takes a Managed Agents parameter, so it needs **both** headers. Pass `betas: ["managed-agents-2026-04-01"]` explicitly on that call (the SDK adds the Files header; you add the Managed Agents one). See `shared/managed-agents-environments.md` -> Session outputs.

Reading Guide

User wants to...	Read these files
Get started from scratch / "help me set up an agent"	`shared/managed-agents-onboarding.md` -- guided interview (WHERE->WHO->WHAT->WATCH), then emit code
Understand how the API works	`shared/managed-agents-core.md`
See the full endpoint reference	`shared/managed-agents-api-reference.md`
Create an agent (required first step)	`shared/managed-agents-core.md` (Agents section) + language file
Update/version an agent	`shared/managed-agents-core.md` (Agents -> Versioning) -- update, don't re-create
Create a session	`shared/managed-agents-core.md` + `{lang}/managed-agents/README.md` (cURL/C#: `curl/managed-agents.md`)
Configure tools and permissions	`shared/managed-agents-tools.md`
Set up MCP servers	`shared/managed-agents-tools.md` (MCP Servers section)
Stream events / handle tool_use	`shared/managed-agents-events.md` + language file
Get notified of session state changes via webhook (no polling)	`shared/managed-agents-webhooks.md` -- Console-registered endpoint, HMAC verify, thin payload + fetch
Define an outcome / rubric-graded iterate loop	`shared/managed-agents-outcomes.md` -- `user.define_outcome` event, grader, `span.outcome_evaluation_*` events
Coordinate multiple agents / subagents / threads	`shared/managed-agents-multiagent.md` -- `multiagent: {type: "coordinator", agents: [...]}` on the agent, session threads, cross-posted tool confirmations
Set up environments	`shared/managed-agents-environments.md` + language file
Run tool execution in your own infra / VPC (self-hosted sandbox)	`shared/managed-agents-self-hosted-sandboxes.md` -- `config:{type:"self_hosted"}`, `ANTHROPIC_ENVIRONMENT_KEY`, `EnvironmentWorker.run()` / `ant beta:worker poll`
Upload files / attach repos	`shared/managed-agents-environments.md` (Resources)
Give agents persistent memory across sessions	`shared/managed-agents-memory.md` -- memory stores, `memory_store` session resource, preconditions, versions/redact
Define agents/environments as version-controlled YAML; drive the API from the shell	`shared/anthropic-cli.md` -- `ant beta:agents create < agent.yaml`, `--transform`, `@file` inlining
Store credentials (MCP auth, API keys for CLIs/SDKs)	`shared/managed-agents-tools.md` (Vaults section) -- `mcp_oauth` / `static_bearer` / `environment_variable`
Call a non-MCP API / CLI that needs a secret	`shared/managed-agents-tools.md` (Vaults section) -- `environment_variable` credential, substituted at egress. If that doesn't fit (e.g. self-hosted sandboxes), `shared/managed-agents-client-patterns.md` Pattern 9 keeps the secret host-side via a custom tool
Run an agent on a recurring cron schedule	`shared/managed-agents-scheduled-deployments.md` -- deployments, deployment runs, pause/auto-pause
Cap a session's spend with a hard dollar budget	`shared/managed-agents-core.md` (? Session budgets) -- `budget` at session create, `budget_reached` pause, change/remove to resume. Deployments: `shared/managed-agents-scheduled-deployments.md` ? Deployment budgets
Pin where model inference runs (data residency)	`shared/managed-agents-core.md` (? Pinning inference

```
geography) -- `model.inference_geo` on the agent, per-session override, roster uniformity |
| Load skills from the codebase instead of uploading | `shared/managed-agents-tools.md` (? Skills from a
GitHub repository) -- root `.claude/skills` discovery at session start |
| Give the session an advisor to consult mid-turn | `shared/managed-agents-multiagent.md` (? Advisor) --
`{type: "advisor", model}` roster entry, consultation threads, plaintext vs redacted delivery |

## Common Pitfalls

- **Agent FIRST, then session -- NO EXCEPTIONS** -- the session's `agent` field accepts **only** a string ID
or `{type: "agent", id, version}`. `model`, `system`, `tools`, `mcp_servers`, `skills` are **top-level fields
on `POST /v1/agents`**, never on `sessions.create()`. If the user hasn't created an agent, that is step zero
of every example.
- **Agent ONCE, not every run** -- `agents.create()` is a setup step. Store the returned `agent_id` and reuse
it; don't call `agents.create()` at the top of your hot path. If the agent's config needs to change, `POST
/v1/agents/{id}` -- each update creates a new version, and sessions can pin to a specific version for
reproducibility.
- **MCP auth goes through vaults** -- the agent's `mcp_servers` array declares `{type, name, url}` only (no
auth). Credentials live in vaults (`client.beta.vaults.credentials.create`) and attach to sessions via
`vault_ids`. Anthropic auto-refreshes OAuth tokens using the stored refresh token. Vaults also hold
`environment_variable` credentials for non-MCP services (CLIs, SDKs, direct API calls) -- substituted at
egress, never visible in the sandbox.
- **Reconcile resources before the first run** -- a session with a clear ask but a missing tool, credential,
data mount, or context will discover the gap mid-run, then flail and give up. Before creating the session,
check that every action in the task maps to a configured tool/MCP server, every MCP server has a vault
credential, and every referenced file/host is mounted/reachable. When helping a user set one up, run the
reconciliation in `shared/managed-agents-onboarding.md` -> ?3 Pre-flight viability check.
- **Stream to get events** -- `GET /v1/sessions/{id}/events/stream` is the primary way to receive agent
output in real-time.
- **SSE stream has no replay -- reconnect with consolidation** -- if the stream drops while a
`agent.tool_use`, `agent.mcp_tool_use`, or `agent.custom_tool_use` is pending resolution
(`user.tool_confirmation` for the first two, `user.custom_tool_result` for the last one), the session
deadlocks (client disconnects -> session idles -> reconnect happens -> no client resolution happens). On
every (re)connect: open stream with `GET /v1/sessions/{id}/events/stream` , fetch `GET
/v1/sessions/{id}/events`, dedupe by event ID, then proceed. See `shared/managed-agents-events.md` ->
Reconnecting after a dropped stream.
- **Don't trust HTTP-library timeouts as wall-clock caps** -- `requests` `timeout=(c, r)` and
`httpx.Timeout(n)` are *per-chunk* read timeouts; they reset every byte, so a trickling connection can block
indefinitely. For a hard deadline on raw-HTTP polling, track `time.monotonic()` at the loop level and bail
explicitly. Prefer the SDK's `sessions.events.stream()` / `sessions.events.list()` over hand-rolled HTTP. See
`shared/managed-agents-events.md` -> Receiving Events.
- **Messages queue** -- you can send events while the session is `running` or `idle`; they're processed in
order. No need to wait for a response before sending the next message. Exception: a session paused at its
budget (`stop_reason: budget_reached`) accepts only settle events -- change or remove the budget to resume
(`shared/managed-agents-core.md` ? Session budgets).
- **Environment `config.type` is `"cloud"` or `"self_hosted"`** -- `cloud` runs the container on Anthropic's
infrastructure; `self_hosted` moves tool execution to your own (see
`shared/managed-agents-self-hosted-sandboxes.md`).
- **Archive is permanent on every resource** -- archiving an agent, environment, session, vault, credential,
or memory store makes it read-only with no unarchive. For agents, environments, and memory stores
specifically, archived resources cannot be referenced by new sessions (existing sessions continue). Do not
call `.archive()` on a production agent, environment, or memory store as cleanup -- **always confirm with the
user before archiving**.
</doc>

<doc path="shared/managed-agents-scheduled-deployments.md">
# Managed Agents -- Scheduled Deployments

A **scheduled deployment** runs an agent on a recurring cron schedule -- each firing creates a session
autonomously. Use it for predictable-cadence work: nightly triage, weekly compliance scans, hourly monitors.

Requires the `managed-agents-2026-04-01` beta header (the SDK sets it automatically for
`client.beta.deployments.*` / `client.beta.deployment_runs.*` calls).

## Create a deployment

A deployment bundles everything a session needs (agent, environment, optional files / GitHub / memory stores
/ vaults) plus a `schedule` and the `initial_events` that kick off each run:

- `agent` and `environment_id` are required -- same shapes as `sessions.create` (see
`shared/managed-agents-core.md`).
```

- `initial_events` must contain at least one starting event -- a `user.message` **or** a `user.define_outcome`. (A deployment's `initial_events` also accepts `system.message`, which a session's does not.)
- `schedule` takes a cron `expression` and an IANA `timezone`. Minute-level granularity is the maximum.

```bash
curl -fsSL https://api.anthropic.com/v1/deployments \
  -H "x-api-key: $ANTHROPIC_API_KEY" \
  -H "anthropic-version: 2023-06-01" \
  -H "anthropic-beta: managed-agents-2026-04-01" \
  -H "content-type: application/json" \
  -d @- <<EOF
{
  "name": "Weekly compliance scan",
  "agent": "$AGENT_ID",
  "environment_id": "$ENVIRONMENT_ID",
  "initial_events": [
    {"type": "user.message", "content": [{"type": "text", "text": "Run the weekly compliance scan."}]}
  ],
  "schedule": {
    "type": "cron",
    "expression": "0 20 * * 5",
    "timezone": "America/New_York"
  }
}
EOF
```

```python
deployment = client.beta.deployments.create(
    name="Weekly compliance scan",
    agent=agent.id,
    environment_id=environment.id,
    initial_events=[
        {
            "type": "user.message",
            "content": [{"type": "text", "text": "Run the weekly compliance scan."}],
        },
    ],
    schedule={
        "type": "cron",
        "expression": "0 20 * * 5",
        "timezone": "America/New_York",
    },
)
```

The response is a deployment object (`depl_` ID prefix). Check `schedule.upcoming_runs_at` -- the next fire times -- to confirm the schedule parses the way you intended:

```json
{
  "id": "depl_01xyz",
  "status": "active",
  "paused_reason": null,
  "schedule": {
    "type": "cron",
    "expression": "0 20 * * 5",
    "timezone": "America/New_York",
    "last_run_at": null,
    "upcoming_runs_at": ["2026-05-09T00:00:00Z", "2026-05-16T00:00:00Z", "2026-05-23T00:00:00Z"]
  }
}
```

`upcoming_runs_at` reflects the exact configured schedule, but **execution is jittered to distribute load: up to 15% of the interval between runs, floored at 5 seconds and capped at 9 minutes.** An hourly deployment can therefore fire up to 9 minutes late; don't build a downstream deadline that assumes the listed timestamp. Maximum **1000 scheduled deployments per organization** (contact Anthropic support for more).

```
### Cron and timezone semantics

- **Expression:** standard POSIX cron (`minute hour day-of-month month day-of-week`).
- **Timezone:** IANA identifier (e.g. `"America/Los_Angeles"`).
- **DST:** literal wall-clock matching -- `"0 20 * * *"` in `America/New_York` fires at 8:00 PM local
regardless of EST/EDT.

> ?? **DST edge:** wall-clock times that don't exist on a spring-forward day (e.g. 2AM) are **skipped**;
times that occur twice on a fall-back day **fire twice**. Schedule outside the 1-3AM local window, or use
UTC, when missed or duplicate executions are unacceptable.

## Deployment budgets

A deployment accepts the same `budget` object as a session (`{type: "limit", max_list_cost: {amount,
currency}}` -- minor-unit cents string, `USD` only; see `shared/managed-agents-core.md` ? Session budgets).
The cap is **copied onto each session at fire time**, and that session then behaves exactly like any budgeted
session.

Deployment budget update semantics differ from a session's:

- `budget` is accepted on **create and update** -- it is not create-only.
- `budget: null` on update **clears** it, and a cleared budget **can be re-added later** -- there is no
one-way door.
- A change applies **from the next fired session** -- sessions already running keep the cap they were created
with (change those via their own session update).

## Deployment runs

Every trigger attempt -- successful or not -- writes a **deployment run** record (`drun_` prefix), so you can
audit failures independent of the session lifecycle. A successful run carries the created `session_id`;
follow that session via the event stream (`shared/managed-agents-events.md`) or webhooks
(`shared/managed-agents-webhooks.md`) as usual. A failed run carries an `error` whose `type` explains why
session creation was rejected.

```python
# All runs for a deployment
for run in client.beta.deployment_runs.list(deployment_id=deployment.id):
    print(run.created_at, run.session_id or run.error.type)

# Failures only
for run in client.beta.deployment_runs.list(deployment_id=deployment.id, has_error=True):
    print(run.created_at, run.error.type, run.error.message)
```

```typescript
for await (const run of client.beta.deploymentRuns.list({
  deployment_id: deployment.id,
  has_error: true,
})) {
  console.log(run.created_at, run.error?.type, run.error?.message);
}
```

Raw HTTP: `GET /v1/deployment_runs?deployment_id=...&has_error=true`. To retrieve a single run by ID, `GET
/v1/deployment_runs/{deployment_run_id}` (SDK: `client.beta.deployment_runs.retrieve(run_id)`) -- a
`deployment_run.*` webhook event carries the run ID as its `data.id`.

A failed run looks like:

```json
{
  "type": "deployment_run",
  "id": "drun_01abc124",
  "deployment_id": "depl_01xyz",
  "trigger_context": { "type": "schedule", "scheduled_at": "2026-05-09T00:00:00Z" },
  "session_id": null,
  "error": { "type": "environment_archived", "message": "environment `env_01abc` is archived" },
  "agent": { "type": "agent", "id": "agent_01ghi789", "version": 3 },
  "created_at": "2026-05-09T00:00:01Z"
}
```
```

```

Error types include `environment_archived`, `agent_archived`, `vault_not_found`, `session_rate_limited`, and
`service_unavailable`.

The outcome of each **scheduled** run (started/succeeded/failed) and each deployment lifecycle change
(created/updated/paused/unpaused/archived/deleted) is also delivered as a webhook event -- see
`shared/managed-agents-webhooks.md` for the `deployment.*` and `deployment_run.*` event types -- so you can
react without polling. Manual runs do **not** emit `deployment_run.*` webhook events.

## Lifecycle: pause / unpause / archive

| Operation | SDK | Effect |
|---|---|---|
| Pause | `client.beta.deployments.pause(id)` | Suppresses scheduled triggers go-forward. Sessions already
running continue. **Manual runs are still permitted while paused.** Sets `paused_reason: {"type": "manual"}`.
|
| Unpause | `client.beta.deployments.unpause(id)` | Resumes from the next scheduled occurrence. **Missed
triggers are not backfilled.** Clears `paused_reason`. |
| Archive | `client.beta.deployments.archive(id)` | **Terminal** -- the schedule stops and the deployment can
no longer be modified. Use pause for anything reversible. |

Raw HTTP: `POST /v1/deployments/{deployment_id}/pause` (likewise `/unpause`, `/archive`).

### Failure behavior

- **Rate-limited:** recorded immediately as a `session_rate_limited` run, **no retry** -- the schedule simply
tries again at the next occurrence. (Rate limits on API calls *inside* a session are handled by the session
itself.)
- **Other failed runs** (e.g. `environment_archived`, `vault_not_found`, `service_unavailable`): the run
records the `error.type` -- monitor runs and fix the referenced resource, or pause the deployment.
- **Agent archived:** the deployment is automatically **archived** (terminal) in the same operation. **Agent
deleted:** the next scheduled trigger detects the missing agent and archives the deployment then. Either way
no deployment run is recorded, and no further sessions are created.

## Manual runs

`POST /v1/deployments/{deployment_id}/run` (SDK: `client.beta.deployments.run(id)`) creates a session
immediately and writes a run with `trigger_context.type: "manual"`. Use it to **test a deployment before
committing to the schedule** -- and remember it works even while the deployment is paused.
</doc>

<doc path="shared/managed-agents-self-hosted-sandboxes.md">
# Managed Agents -- Self-Hosted Sandboxes

With `config.type: "self_hosted"`, the **agent loop stays on Anthropic's orchestration layer** but **tool
execution moves to infrastructure you control** -- bash, file ops, and code run inside your container, so
filesystem contents and network egress never leave your environment. Contrast with `config.type: "cloud"`,
where Anthropic runs the container. Connectivity is **outbound-only**: your worker long-polls Anthropic's
work queue; Anthropic never dials into your network.

## Flow

```
1. Create environment: config: {type: "self_hosted"}   -> env_...
2. Generate environment key (Console, on the environment page)   -> sk-ant-oat01-... as
ANTHROPIC_ENVIRONMENT_KEY
3. Run a worker: EnvironmentWorker.run() or ant beta:worker poll
4. Sessions reference   environment_id=env_... exactly as for cloud
```

## Create the environment

```python
client = anthropic.Anthropic()

environment = client.beta.environments.create(
    name="self-hosted", config={"type": "self_hosted"}
)
```
```

`{"type": "self_hosted"}` is the entire config -- there are no pool, capacity, or networking sub-fields; you control those on your side.

Run a worker -- SDK (primary path)

`EnvironmentWorker` wraps the poll -> dispatch -> tool-execute loop. `.run()` is the always-on loop; `.run_one()` / `.runOne()` handles one work item (for webhook-driven wake).

Python -- always-on:

```python
import asyncio
import os
from anthropic import AsyncAnthropic
from anthropic.lib.environments import EnvironmentWorker

async def main() -> None:
    environment_key = os.environ["ANTHROPIC_ENVIRONMENT_KEY"]
    environment_id = os.environ["ANTHROPIC_ENVIRONMENT_ID"]
    async with AsyncAnthropic(auth_token=environment_key) as client:
        await EnvironmentWorker(
            client,
            environment_id=environment_id,
            environment_key=environment_key,
            workdir="/workspace",
        ).run()

asyncio.run(main())
```

TypeScript -- always-on:

```typescript
import Anthropic from "@anthropic-ai/sdk";
import { EnvironmentWorker } from "@anthropic-ai/sdk/helpers/beta/environments";

const environmentKey = process.env.ANTHROPIC_ENVIRONMENT_KEY!;
const environmentId = process.env.ANTHROPIC_ENVIRONMENT_ID!;
const client = new Anthropic({ authToken: environmentKey });
const ctrl = new AbortController();
process.once("SIGTERM", () => ctrl.abort());

await new EnvironmentWorker({
  client,
  environmentId,
  environmentKey,
  workdir: "/workspace",
  signal: ctrl.signal
}).run();
```

Customizing tools. `EnvironmentWorker` runs the built-in toolset by default. To add or replace tools, use `AgentToolContext(workdir=, client=, session_id=)` with `beta_agent_toolset(env)` / `betaAgentToolset(env)` and pass the resulting tools to the lower-level `tool_runner()`. Skills attached to the agent are downloaded into `{workdir}/skills/<name>/` before tool calls begin (`AgentToolContext` handles this when given `client` and `session_id`). Downloaded skill files are marked executable automatically by the CLI and SDK; if you implement skills download yourself, you set permissions.

> **Runtime deps:** the SDK helpers require `/bin/bash` at that exact path. The TypeScript SDK additionally requires `unzip`, `tar`, and Node.js 22+. These are resolved at fixed paths and do **not** respect `PATH` overrides.

Run a worker -- `ant` CLI (fixed tools)

The `ant` CLI ships a worker with the fixed built-in toolset (`bash`, `read`, `write`, `edit`, `glob`, `grep`). Install per `shared/anthropic-cli.md`, then:

```sh
export ANTHROPIC_ENVIRONMENT_KEY=sk-ant-oat01-...
ant beta:worker poll --environment-id env_... --workdir /workspace
```

- `--workdir` is the directory tools operate in (default `.`); tool calls are sandboxed to it.
- `--environment-key` overrides the env var.
- `--on-work <script>` runs your script per work item (e.g. to spin a fresh container per session -- see Container orchestration below).
- `--unrestricted-paths`, `--max-idle` (default `60s`), `--log-format` -- see `ant beta:worker poll --help`.
- Flags fall back to env vars (`ANTHROPIC_ENVIRONMENT_ID`, `ANTHROPIC_ENVIRONMENT_KEY`).
- Exits cleanly on SIGTERM/SIGINT after draining in-flight work.
- **Fixed toolset** -- for custom tools, use the SDK worker above.

Inside an `--on-work` container, run `ant beta:worker run --workdir <dir>` as the entrypoint.

Webhook-driven wake (instead of always-on)

Register a webhook for `session.status_run_started` (see `shared/managed-agents-webhooks.md`), verify the delivery, then drain one work item with `.run_one()`:

```python
import os
import anthropic
from anthropic.lib.environments import EnvironmentWorker

environment_key = os.environ["ANTHROPIC_ENVIRONMENT_KEY"]
environment_id = os.environ["ANTHROPIC_ENVIRONMENT_ID"]
client = anthropic.AsyncAnthropic(
    auth_token=environment_key,
)  # reads ANTHROPIC_WEBHOOK_SIGNING_KEY from env for webhooks.unwrap()

async def handle(raw: bytes, headers: dict[str, str]) -> dict:
    event = client.beta.webhooks.unwrap(raw.decode(), headers=headers)
    if event.data.type != "session.status_run_started":
        return {"status": "ignored"}
    await EnvironmentWorker(
        client,
        environment_id=environment_id,
        environment_key=environment_key,
        workdir="/workspace",
    ).run_one()
    return {"status": "ok"}
```

TypeScript: same shape with `client.beta.webhooks.unwrap(body, {headers})` and `new EnvironmentWorker({...}).runOne()`.

Container orchestration (mid-level)

`EnvironmentWorker.run()` polls and executes tools in the same process. To run each session in its **own** container, use the mid-level poller in a thin orchestrator -- Python `client.beta.environments.work.poller(environment_id=, environment_key=, drain=, block_ms=, reclaim_older_than_ms=, auto_stop=)`; TypeScript `new WorkPoller({client, environmentId, environmentKey, autoStop})` from `@anthropic-ai/sdk/helpers/beta/environments` -- and, for each yielded `work` item, start a fresh container with these env vars injected, whose entrypoint runs `ant beta:worker run` or an `EnvironmentWorker(...).run_one()`. `block_ms` is 1-999 (or `None` for non-blocking); `reclaim_older_than_ms` re-claims items leased to a dead worker; `drain` stops once the queue is empty; `auto_stop` posts a stop signal after the iterator exits (set `False` when the launched container owns the stop call). **Go's poller has no `auto_stop` opt-out** -- it calls `work.Stop` when the handler returns, so block in the handler until the session completes rather than detaching.

Env var	Value
`ANTHROPIC_SESSION_ID`	`work.data.id`
`ANTHROPIC_WORK_ID`	`work.id`
`ANTHROPIC_ENVIRONMENT_ID`	`work.environment_id`
`ANTHROPIC_ENVIRONMENT_KEY`	pass through
`ANTHROPIC_BASE_URL`	pass through

```
Skip items where `work.data.type != "session"`.

## Monitoring & control

These are **control-plane** calls -- authenticate with `x-api-key` (not the environment key);
`managed-agents-2026-04-01` beta header. **Call them from outside the worker host** -- setting
`ANTHROPIC_API_KEY` on the worker host exposes an organization-scoped credential to agent tool calls.

| SDK (`client.beta.environments.work.*`) | REST | CLI | Returns |
|---|---|---|---|
| `stats(environment_id)` | `GET /v1/environments/{id}/work/stats` | `ant beta:environments:work stats` |
`{type:"work_queue_stats", depth, pending, oldest_queued_at, workers_polling}` |
| `stop(work_id, environment_id=)` | `POST /v1/environments/{id}/work/{work_id}/stop` | `ant
beta:environments:work stop` | `work.state` |

## What changes vs `cloud`

| Concern | `cloud` | `self_hosted` |
|---|---|---|
| Container lifecycle, hardening, networking | Anthropic | **You** -- run non-root, read-only rootfs, drop
caps; egress is whatever your VPC/firewall allows |
| `file` / `github_repository` resource mounting | Anthropic mounts into the container | **You** -- pass
pointers via `sessions.create(metadata={...})` and have your orchestrator fetch/clone before dispatch |
| `memory_store` resources | Supported | **Not yet supported** |
| Vault `environment_variable` credentials | Supported (substituted at Anthropic-managed egress) | **Not yet
supported** -- egress is yours, so there's nowhere to substitute the secret. Use MCP credentials or a
host-side custom tool (`shared/managed-agents-client-patterns.md` Pattern 9) |
| Built-in tools | Via `agent_toolset_20260401` | Supplied by your worker (`EnvironmentWorker` default /
`beta_agent_toolset(env)` / `ant` CLI fixed set) |
| Skills download | Automatic | `EnvironmentWorker` / `AgentToolContext` fetch into `{workdir}/skills/`
(needs `client` + `session_id`) |
| Claude Platform on AWS | Supported | **Not available** |
| SDK worker helpers | All SDKs | **Python, TypeScript, Go only** (`EnvironmentWorker` / poller not in Java,
Ruby, PHP, or C#) -- use one of those three or the `ant` CLI |

## Credentials

| Credential | Format | Scope |
|---|---|---|
| `ANTHROPIC_ENVIRONMENT_KEY` | `sk-ant-oat01-...` | One environment's work queue. Generate in Console
("Generate environment key"). Pass as `auth_token=` / `authToken` on the client **and** as `environment_key=`
/ `environmentKey` on `EnvironmentWorker`. Store in a secrets manager; rotate on exposure. |
| `ANTHROPIC_WEBHOOK_SIGNING_KEY` | `whsec_...` | Webhook signature verification (if using webhook-driven
wake). The SDK reads this env var automatically for `client.beta.webhooks.unwrap()`. |

## Security -- what you own

Container hardening; egress restriction (there is no default); `ANTHROPIC_ENVIRONMENT_KEY` custody and
rotation; one workspace + environment per trust boundary when running untrusted code; least-privilege for the
tool process; log retention and redaction. **Anthropic cannot**: fast-revoke a leaked environment key, verify
your image or supply chain, sandbox tool execution inside your container, or enforce retention after tool
output reaches your infrastructure. See the Self-Hosted Sandboxes Security page in `shared/live-sources.md`
for the full checklist.
</doc>

# Managed Agents -- Tools & Skills

## Tools

### Server tools vs client tools

| Type | Who runs it | How it works |
|---|---|---|
| **Prebuilt Claude Agent tools** (`agent_toolset_20260401`) | Anthropic, on the session's container (for
`cloud` envs; for `self_hosted`, **your** worker supplies and runs them -- see
`shared/managed-agents-self-hosted-sandboxes.md`) | File ops, bash, web search, etc. Enable all at once or
configure individually with `enabled: true/false`. |
| **MCP tools** (`mcp_toolset`) | Anthropic's orchestration layer | Capabilities exposed by connected MCP
```

```
servers. Grant access per-server via the toolset. |
| **Custom tools** | **You** -- your application handles the call and returns results | Agent emits a
`agent.custom_tool_use` event, session goes `idle`, you send back a `user.custom_tool_result` event. |

**Recommendation:** Enable all prebuilt tools via `agent_toolset_20260401`, then disable individually as
needed.

**Versioning:** The toolset is a versioned, static resource. When underlying tools change, a new toolset
version is created (hence `_20260401`) so you always know exactly what you're getting.

### Agent Toolset

The `agent_toolset_20260401` provides these built-in tools:

| Tool                   | Description                                |
| ---------------------- | ------------------------------------------ |
| `bash` | Execute bash commands in a shell session |
| `read` | Read a file from the local filesystem, including text, images, PDFs, and Jupyter notebooks |
| `write` | Write a file to the local filesystem |
| `edit` | Perform string replacement in a file |
| `glob` | Fast file pattern matching using glob patterns |
| `grep` | Text search using regex patterns |
| `web_fetch` | Fetch content from a URL |
| `web_search` | Search the web for information |

Enable the full toolset:

```json
{
  "tools": [
    { "type": "agent_toolset_20260401" }
  ]
}
```

Per-Tool Configuration

Override defaults for individual tools. This example enables everything except bash:

```json
{
  "tools": [
    {
      "type": "agent_toolset_20260401",
      "default_config": { "enabled": true },
      "configs": [
        { "name": "bash", "enabled": false }
      ]
    }
  ]
}
```

Field	Required	Description
`type`	?	`"agent_toolset_20260401"`
`default_config`	?	Applied to all tools. `{ "enabled": bool, "permission_policy": {...} }`
`configs`	?	Per-tool overrides: `[{ "name": "...", "enabled": bool, "permission_policy": {...} }]`

Permission Policies

Control when server-executed tools (agent toolset + MCP) run automatically vs wait for approval. Does not
apply to custom tools.

Policy	Behavior
`always_allow`	Tool executes automatically (default)
`always_ask`	Session emits `session.status_idle` and pauses until you send a `user.tool_confirmation`
event
```

```json
{
  "type": "agent_toolset_20260401",
  "default_config": {
    "enabled": true,
    "permission_policy": { "type": "always_allow" }
  },
  "configs": [
    { "name": "bash", "permission_policy": { "type": "always_ask" } }
  ]
}
```

Responding to `always_ask`: Send a `user.tool_confirmation` event with `tool_use_id` from the triggering `agent_tool_use`/`mcp_tool_use` event:

```json
{ "type": "user.tool_confirmation", "tool_use_id": "sevt_abc123", "result": "allow" }
{ "type": "user.tool_confirmation", "tool_use_id": "sevt_def456", "result": "deny", "message": "Read .env.example instead" }
```

The optional `message` on a deny is delivered to the agent so it can adjust its approach.

To enable only specific tools, flip the default off and opt-in per tool:

```json
{
  "tools": [
    {
      "type": "agent_toolset_20260401",
      "default_config": { "enabled": false },
      "configs": [
        { "name": "bash", "enabled": true },
        { "name": "read", "enabled": true }
      ]
    }
  ]
}
```

Custom Tools (Client-Side)

Custom tools are executed by **your application**, not Anthropic. The flow:

1. Agent decides to use the tool -> session emits a `agent.custom_tool_use` event with inputs
2. Session goes `idle` waiting for you
3. Your application executes the tool
4. You send back a `user.custom_tool_result` event with the output
5. Session resumes `running`

No permission policy needed -- you're the one executing.

```json
{
  "tools": [
    {
      "type": "custom",
      "name": "get_weather",
      "description": "Fetch current weather for a city.",
      "input_schema": {
        "type": "object",
        "properties": {
          "city": { "type": "string", "description": "City name" }
        },
        "required": ["city"]
      }
    }
  ]
}
```

```

### MCP Servers

MCP (Model Context Protocol) servers expose standardized third-party capabilities (e.g. Asana, GitHub,
Linear). **Configuration is split across agent and vault:**

1. **Agent creation** declares which servers to connect to (`type`, `name`, `url` -- no auth). The agent's
`mcp_servers` array has no auth field.
2. **Vault** stores the OAuth credentials. Attach via `vault_ids` on session create.

This keeps secrets out of reusable agent definitions. Each vault credential is tied to one MCP server URL;
Anthropic matches credentials to servers by URL.

**Agent side -- declare servers (no auth):**

| Field | Required | Description |
|---|---|---|
| `type` | ? | `"url"` |
| `name` | ? | Unique name -- referenced by `mcp_toolset.mcp_server_name` |
| `url` | ? | The MCP server's endpoint URL (Streamable HTTP transport) |

```json
{
  "mcp_servers": [
    { "type": "url", "name": "linear", "url": "https://mcp.linear.app/mcp" }
  ],
  "tools": [
    { "type": "mcp_toolset", "mcp_server_name": "linear" }
  ]
}
```

Session side -- attach vault:

```json
{
  "agent": "agent_abc123",
  "environment_id": "env_abc123",
  "vault_ids": ["vlt_abc123"]
}
```

> ? **Per-tool enablement (empirical):** `mcp_toolset` has been observed accepting `default_config: {enabled:
false}` + `configs: [{name, enabled: true}]` for an allowlist pattern. The API ref shows only the minimal
`{type, mcp_server_name}` form.

> ? **Changing tools/MCP servers on a running session:** `sessions.update()` can replace `agent.tools` and
`agent.mcp_servers` while the session is `idle` -- a session-local override that doesn't touch the agent
object. `vault_ids` is create-only. See `shared/managed-agents-core.md` -> Updating the agent configuration
mid-session.

Large tool outputs. If a tool returns more than **100,000 characters (roughly 25,000 tokens)**, the
output is automatically offloaded to a file in the sandbox -- the agent receives a truncated preview plus the
file path and can `read` the full content. No configuration required. The threshold is in *characters*, not
tokens, and applies to built-in agent tools as well as MCP tools.

Invalid vault credentials don't block session creation. If a vault credential is invalid for a declared
MCP server, the session still creates successfully; a `session.error` event describes the MCP auth failure,
and auth retries on the next `session.status_idle` -> `session.status_running` transition.

> ?? **MCP auth tokens != REST API tokens.** Hosted MCP servers (`mcp.notion.com`, `mcp.linear.app`, etc.)
typically require **OAuth bearer tokens**, not the service's native API keys. A Notion `ntn_` integration
token authenticates against Notion's REST API but will **not** work as a vault credential for the Notion MCP
server. These are different auth systems.

Vaults -- the credential store

Vaults store credentials that Anthropic manages on your behalf. Two credential categories:
```

```
- **MCP credentials** (`mcp_oauth`, `static_bearer`) -- keyed by `mcp_server_url`. When the agent connects to a server at that URL, the token is injected automatically. **Matching is normalized, not byte-exact:** scheme and host are lowercased, and default ports and trailing slashes are stripped, so host casing, an explicit default port, or a trailing slash won't break the match. A different path, subdomain, or *non-default* port will. If nothing matches, the connection is attempted unauthenticated. `mcp_oauth` tokens are auto-refreshed via the standard OAuth 2.0 `refresh_token` grant. This is the only way to authenticate MCP servers.
- **Environment variables** (`environment_variable`) -- keyed by `secret_name` (the env var name). The sandbox sees only an **opaque placeholder**; the real secret is substituted into the outbound request **at egress**. Use this for any service that authenticates through an environment variable: CLIs (`aws`, `gcloud`, `stripe`), SDKs, or direct `curl` calls from the `bash` tool.

Secret fields you supply (`token`, `access_token`, `refresh_token`, `client_secret`, `secret_value`) are write-only -- never returned in API responses.

#### Credentials and the sandbox

Vaults store credentials; those credentials **never enter the sandbox**. This is a deliberate security boundary -- code running in the sandbox (including anything the agent writes) cannot read or exfiltrate a vaulted credential, even under prompt injection. Instead, credentials are injected by Anthropic-side proxies **after** a request leaves the sandbox:

- **MCP tool calls** are routed through an Anthropic-side proxy that fetches the credential from the vault and adds it to the outbound request.
- **Git operations on attached GitHub repositories** (`git pull`, `git push`, GitHub REST calls) are routed through a git proxy that injects the `github_repository` resource's `authorization_token` the same way.
- **Environment-variable credentials** appear in the sandbox as an opaque placeholder; the real value replaces the placeholder at egress, on requests to the credential's allowed hosts only. Substitution covers request **headers and body only** -- a secret embedded in the **URL path** is never substituted, so path-secret endpoints (e.g. Slack incoming-webhook URLs) can't be vaulted; use header-based auth instead (for Slack: a bot token in `Authorization` via `chat.postMessage`).

**When vault credentials don't fit** (e.g. self-hosted sandboxes -- `environment_variable` is not yet supported there), **register a custom tool:** the agent emits `agent.custom_tool_use`, your orchestrator (which already holds the credential) executes the call and returns `user.custom_tool_result` over the same authenticated event stream. No public endpoint is exposed; the sandbox never sees the secret. See `shared/managed-agents-client-patterns.md` -> Pattern 9.

**Do not put API keys in the system prompt or user messages as a workaround** -- they persist in the session's event history.

> Formerly known internally as TATs (Tool/Tenant Access Tokens).

**Flow:**

1. Create a vault (`client.beta.vaults.create(...)`) -- one per tenant/user, or one shared, depending on your model
2. Add credentials to it (`client.beta.vaults.credentials.create(...)`) -- MCP credentials are keyed by MCP server URL; environment-variable credentials by `secret_name`
3. Reference the vault on session create via `vault_ids: ["vlt_..."]`
4. Anthropic auto-refreshes OAuth tokens before they expire and substitutes secrets at runtime

**MCP OAuth credential shape**:

```json
{
  "display_name": "Notion (workspace-foo)",
  "auth": {
    "type": "mcp_oauth",
    "mcp_server_url": "https://mcp.notion.com/mcp",
    "access_token": "<current access token>",
    "expires_at": "2026-04-02T14:00:00Z",
    "refresh": {
      "refresh_token": "<refresh token>",
      "client_id": "<your OAuth client_id>",
      "token_endpoint": "https://api.notion.com/v1/oauth/token",
      "token_endpoint_auth": { "type": "none" }
    }
  }
}
```
```

The `refresh` block is what enables auto-refresh -- `token_endpoint` is where Anthropic posts the `refresh_token` grant. `token_endpoint_auth` is a discriminated union:

`type`	Shape	Use when
`"none"`	`{type: "none"}`	Public OAuth client (no secret)
`"client_secret_basic"`	`{type: "client_secret_basic", client_secret: "..."}`	Confidential client, secret via HTTP Basic auth
`"client_secret_post"`	`{type: "client_secret_post", client_secret: "..."}`	Confidential client, secret in request body

Omit `refresh` entirely if you only have an access token with no refresh capability -- it'll work until it expires, then the agent loses access.

> ? **Getting an OAuth token.** How you obtain the initial access and refresh tokens depends on the MCP server -- consult its documentation. Once you have them, store them in a vault credential using the shape above; Anthropic auto-refreshes via the `refresh.token_endpoint` from there.

Environment-variable credential shape:

```json
{
  "display_name": "Twilio API key for sandbox",
  "auth": {
    "type": "environment_variable",
    "secret_name": "TWILIO_API_KEY",
    "secret_value": "sk-your-secret-here",
    "networking": {
      "type": "limited",
      "allowed_hosts": ["api.twilio.com", "*.twilio.com"]
    }
  }
}
```

`networking.allowed_hosts` controls which outbound hosts the secret can be substituted for -- `{"type": "limited", "allowed_hosts": [...]}` or `{"type": "unrestricted"}` if you can't enumerate the domains in advance. Limiting is strongly recommended: it prevents the key from ever being sent to unauthorized hosts.

`injection_location` (optional, sibling of `networking`) controls **where** in the outbound request the secret is substituted -- `{header: bool, body: bool}`. The two are independent: `allowed_hosts` scopes *which hosts* a substituted request can target; `injection_location` scopes *which parts of the request* the secret is substituted into across all of those hosts. Most services read an API key from a request header, so `{"header": true}` is the narrower configuration -- request bodies are often assembled from content the agent is working with, making the body the broader exposure surface. A placeholder in a disabled location is **neither substituted nor stripped** -- the literal opaque placeholder string is sent to the third party in that location.

Operation	`injection_location` semantics
Create credential	Omit the field entirely -> both locations enabled. Provide the object -> any field you omit defaults to `false` (`{"header": true}` creates a header-only credential).
Update credential	Fields **merge individually** -- `{"body": false}` disables body substitution and leaves `header` unchanged. For a running session, the update takes effect on the session's next operation.

A credential must have at least one location enabled; a create or update that would disable both returns 400, as does explicit `null` for the object or either field (omit instead). The response always returns both fields with their resolved values.

> ?? **Credentials created in the Console are header-only by default** -- unlike the API, where omitting the field enables both. If your client sends the secret in the request body (a form-encoded token request, for example), the placeholder passes through literally and the service rejects it with its own authentication error. Tick body injection in the Console form, or `POST` the credential with `{"injection_location": {"body": true}}`.

> ?? **Two networking layers, both required.** `networking.allowed_hosts` on the credential controls which requests *use the secret*, not which requests are *allowed*. The agent must also be able to reach the domain at the **environment level** (`unrestricted`, or the host listed in the environment's `allowed_hosts` -- see `shared/managed-agents-environments.md`). A domain missing from either layer means the secret-substituted

request fails.

> ?? **Client-side validation caveat.** Substitution happens at egress, not inside the sandbox -- clients that validate the credential *format* locally before making a network request (e.g. a CLI that checks the key starts with `sk-`) will see the opaque placeholder and may fail at startup. If a client rejects the credential before any network call, that's why.

> ? **Scope the key minimally.** The agent can do anything the key allows; a key with broader permissions than the task needs increases the blast radius if the agent behaves unexpectedly.

Not supported with self-hosted sandboxes -- `environment_variable` credentials require Anthropic-managed egress. See `shared/managed-agents-self-hosted-sandboxes.md`.

Constraints (all credential types):

- **Unique key per vault.** `mcp_server_url` (MCP credentials) and `secret_name` (environment-variable credentials) must be unique among active credentials in a vault; duplicates return a 409.
- **Keys are immutable.** Secret values, `display_name`, and (on environment-variable credentials) `injection_location` can be updated; to change `mcp_server_url`, `secret_name`, `token_endpoint`, or `client_id`, archive the credential and create a new one. Archiving purges the secret and frees the key for a replacement.
- **Maximum 20 credentials per vault.**
- Credentials are stored as provided and **not validated until session runtime** -- an invalid credential surfaces as an authentication or downstream error during the session, which is emitted but does not block the session from continuing.

Scoping: Vaults are workspace-scoped. Anyone with developer+ role in the API workspace can create, read (metadata only -- secrets are write-only), and attach vaults. `vault_ids` can be set at session **create** time but not via session update (the SDK docstring says "Not yet supported; requests setting this field are rejected").

Skills

Skills are reusable, filesystem-based resources that provide your agent with domain-specific expertise: workflows, context, and best practices that transform general-purpose agents into specialists. Unlike prompts (conversation-level instructions for one-off tasks), skills load on-demand and eliminate the need to repeatedly provide the same guidance across multiple conversations.

Skills reach the agent two ways: **attached** through the agent's `skills` array, or **loaded from a GitHub repository** mounted on the session (see ? Skills from a GitHub repository below). The agent automatically uses them when relevant to the task at hand:

Type	What it is
Pre-built Anthropic skills	Common document tasks (PowerPoint, Excel, Word, PDF). Reference by name (e.g. `xlsx`).
Custom skills	Skills you've created in your organization via the Skills API. Reference by `skill_id` + optional `version`.

Max 20 skills per agent. Agent creation uses `managed-agents-2026-04-01`; the separate Skills API (for managing custom skill definitions) uses `skills-2025-10-02`.

Enabling skills on a session

Skills are attached to the **agent** definition via `agents.create()`:

```ts
const agent = await client.beta.agents.create(
  {
    name: "Financial Agent",
    model: "claude-opus-5",
    system: "You are a financial analysis agent.",
    skills: [
      { type: "anthropic", skill_id: "xlsx" },
      { type: "custom", skill_id: "skill_abc123", version: "latest" },
    ],
  }
);
```

```

Python:

```python
agent = client.beta.agents.create(
    name="Financial Agent",
    model="claude-opus-5",
    system="You are a financial analysis agent.",
    skills=[
        {"type": "anthropic", "skill_id": "xlsx"},
        {"type": "custom", "skill_id": "skill_abc123", "version": "latest"},
    ]
)
```

Skill reference fields:

Field	Anthropic skill	Custom skill
`type`	`"anthropic"`	`"custom"`
`skill_id`	Skill name (e.g. `"xlsx"`, `"docx"`, `"pptx"`, `"pdf"`)	Skill ID from Skills API (e.g. `"skill_abc123"`)
`version`	`"latest"` or a specific version number	`"latest"` or a specific version number

`version` is optional on **both** kinds and defaults to `"latest"` -- it is not custom-skill-only.

Skills from a GitHub repository

Skills can also live in your codebase. When a session mounts a repository via the `github_repository` resource (see `shared/managed-agents-environments.md` -> GitHub Repositories), the repository's root `.claude/skills` directory is scanned at session start, and each skill found becomes available to the agent: it sees each discovered skill's name, description, and sandbox path, and reads the skill's `SKILL.md` (plus any scripts/resources it ships) when a task matches.

The agent can discover any skill in `.claude/skills/<skill-name>/` -- one directory level deep at the repository root. Skills in the following locations are not discoverable: a bare `.claude/skills/SKILL.md` (no skill directory), anything nested deeper (`.claude/skills/tools/code-review/SKILL.md`), a `skills/` directory outside `.claude`, or a `.claude/skills` inside a package subdirectory (though those can still surface when the agent reads files under that subtree). The `SKILL.md` format is the same as uploaded custom skills.

> ?? **Repository skills are agent instructions -- treat them as part of your trust boundary.** Anyone who can commit to a mounted repository (a merged external PR, a compromised dependency, a contributor) can add or edit `.claude/skills/` content, and the platform loads it at session start with no review step -- where session tools like `bash` and `web_fetch` give injected instructions real capability. Only mount repositories you trust, and audit `.claude/skills/` before mounting one with external contributors.

Rules:
- **Cloud sandboxes only** -- self-hosted sandboxes don't support `github_repository` resources, so they can't load repository skills.
- **Scanned once, at session start**, from the repository state checked out then (the resource's `checkout` branch/commit, else the default branch). Commits pushed mid-session are not picked up -- start a new session for updated skills. Repositories added to a *running* session are not scanned either.
- **Coexists with attached skills.** If a repository skill shares a name with an attached skill (or a skill from another mounted repo), both are available, each announced with its own path.

Skills API

Operation	Method	Path
Create Skill	`POST`	`/v1/skills`
List Skills	`GET`	`/v1/skills`
Get Skill	`GET`	`/v1/skills/{id}`
Delete Skill	`DELETE`	`/v1/skills/{id}`
Create Version	`POST`	`/v1/skills/{id}/versions`
List Versions	`GET`	`/v1/skills/{id}/versions`
Get Version	`GET`	`/v1/skills/{id}/versions/{version}`
Delete Version	`DELETE`	`/v1/skills/{id}/versions/{version}`
</doc>
```

<doc path="shared/managed-agents-webhooks.md">
# Managed Agents -- Webhooks

Anthropic can POST to your HTTPS endpoint when a Managed Agents resource changes state -- an alternative to
holding an SSE stream or polling. Payloads are **thin** (event type + resource IDs only); on receipt, fetch
the resource for current state. Every delivery is HMAC-signed.

> **Direction matters.** This page covers *Anthropic -> you* notifications about session/vault state. It does
**not** cover *third-party -> you* webhooks that *trigger* a session (e.g. a GitHub push handler that calls
`sessions.create()`) -- that's ordinary application code on your side with no Anthropic-specific wire format.

---

## Register an endpoint (Console only)

Console -> **Manage -> Webhooks**. There is no programmatic endpoint-management API yet. Secret rotation is
supported from the same page.

| Field | Constraint |
|---|---|
| URL | HTTPS on port 443, publicly resolvable hostname |
| Event types | Subscribe per `data.type` -- an endpoint receives only the types it is subscribed to |
| Signing secret | `whsec_`-prefixed, 32 bytes, **shown once at creation** -- store it |

---

## Verify the signature

Every delivery carries the `webhook-id`, `webhook-timestamp`, and `webhook-signature` headers. **Use the
SDK's `client.beta.webhooks.unwrap()`** -- it verifies the signature, rejects payloads more than ~5 minutes
old, and returns the parsed event. It reads the `whsec_` secret from `ANTHROPIC_WEBHOOK_SIGNING_KEY`. Pass
the headers through untouched; don't hand-roll verification against a single `X-Webhook-Signature` header,
which is not the wire format.

```python
import anthropic
from flask import Flask, request

client = anthropic.Anthropic()  # reads ANTHROPIC_WEBHOOK_SIGNING_KEY from env
app = Flask(__name__)

@app.route("/webhook", methods=["POST"])
def webhook():
    try:
        event = client.beta.webhooks.unwrap(
            request.get_data(as_text=True),
            headers=dict(request.headers),
        )
    except Exception:
        return "invalid signature", 400

    if event.id in seen_event_ids:  # dedupe retries -- id is per-event, not per-delivery
        return "", 204
    seen_event_ids.add(event.id)

    match event.data.type:
        case "session.status_idled":
            session = client.beta.sessions.retrieve(event.data.id)
            notify_user(session)
        case "vault_credential.refresh_failed":
            alert_oncall(event.data.id)

    return "", 204
```

Pass the **raw request body** to `unwrap()` -- frameworks that re-serialize JSON (Express `.json()`, Flask
`.get_json()`) change the bytes and break the MAC. For other languages, look up the `beta.webhooks.unwrap`
binding in the SDK repo (`shared/live-sources.md`); don't hand-roll verification.
````

```
---

## Payload envelope

```json
{
  "type": "event",
  "id": "whe_9d5c1f7e...",
  "created_at": "2026-03-18T14:05:22Z",
  "data": {
    "type": "session.status_idled",
    "id": "session_01XYZ...",
    "organization_id": "8a3d2f1e-...",
    "workspace_id": "c7b0e4d9-..."
  }
}
```

Switch on `data.type`, fetch the resource by `data.id`, return any **2xx** to acknowledge. `created_at` is
when the *event occurred*, not when the delivery was attempted -- the `webhook-timestamp` header is the clock
for the attempt (see Delivery behavior).

The top-level `id` is the same value as the `webhook-id` header, and it is per *event*, not per delivery --
every retry carries it unchanged. Dedupe on it.

Supported `data.type` values

`data.type`	Fires when
`session.status_scheduled`	Session created and ready to accept events
`session.status_run_started`	Agent execution kicked off (every transition to `running`)
`session.status_idled`	Agent awaiting input (tool approval, custom tool result, or next message) -- or
paused at its session budget. The webhook payload is thin -- list the session's events and check the latest
`session.status_idle` event's `stop_reason` (the session object itself has no `stop_reason` field): if it is
`budget_reached`, further `user.message` events return a 400 and only a budget change/removal resumes the
session (`shared/managed-agents-core.md` ? Session budgets)
`session.status_rescheduled`	A transient error occurred; the session is retrying automatically
`session.status_terminated`	Session ended -- **on completion or on error**, not error-only
`session.thread_created`	Multiagent: coordinator opened a new subagent thread, or the session's advisor
is being consulted (`shared/managed-agents-multiagent.md` -> Advisor)
`session.thread_idled`	Child threads only: a subagent thread is waiting for input -- or paused because
the session reached its budget cap. When the whole session pauses at the cap, a `session.status_idled`
webhook also fires and the stream's `session.status_idle` event carries `stop_reason: budget_reached` --
unless another thread is waiting on a tool ask, which outranks the cap at the session level
(`shared/managed-agents-core.md` ? Session budgets).
`session.thread_terminated`	A thread ended -- child completed its work, or the thread was archived.
Child threads only; the primary thread's end surfaces as `session.status_terminated`
`session.outcome_evaluation_ended`	Outcome grader finished one iteration
`session.updated`	Session properties changed (name, configuration)
`session.deleted`	Session permanently deleted -- no object left to fetch; treat the event itself as final
`vault.archived`	Vault was archived
`vault.created`	Vault was created
`vault.deleted`	Vault was deleted -- a `vault_credential.deleted` also fires per underlying credential.
No object left to fetch; treat the event itself as final
`vault_credential.archived`	Credential archived, directly or via vault archival
`vault_credential.created`	Vault credential was created
`vault_credential.deleted`	Credential deleted, directly or via vault deletion. No object left to fetch;
treat the event itself as final
`vault_credential.refresh_failed`	MCP OAuth vault credential failed to refresh
`agent.created`	Agent created
`agent.updated`	A new agent version was published. Updates that do not create a new version do **not**
fire this.
`agent.archived`	Agent archived
`agent.deleted`	Agent permanently deleted -- no object left to fetch; treat the event itself as final
`deployment.created`	Scheduled deployment created
`deployment.updated`	Deployment properties changed (e.g. schedule edited)
`deployment.paused`	Deployment paused -- by request, or automatically when a scheduled run fails with a
```

```
**non-recoverable** error (archived agent, missing environment). Recoverable failures, including rate limits,
do **not** auto-pause. |
| `deployment.unpaused` | Deployment unpaused; schedule resumes |
| `deployment.archived` | Deployment archived -- directly, or as a result of agent archival/deletion |
| `deployment.deleted` | Deployment permanently deleted -- no object left to fetch; treat the event itself as
final |
| `deployment_run.started` | A **scheduled** run started. Manual runs do **not** emit `deployment_run.*`
events. |
| `deployment_run.succeeded` | Scheduled run created its session. Same `data.id` (the run ID) as the run's
`.started` event -- fetch the deployment run for its `session_id`, then subscribe to the session events to
follow the work. |
| `deployment_run.failed` | Scheduled run did not create a session. Same `data.id` as the run's `.started`
event -- fetch the deployment run for `error.type` / `error.message`. |
| `environment.created` | Environment created |
| `environment.updated` | Environment updated with at least one changed field. A no-op update emits nothing. |
| `environment.archived` | Environment archived. Re-archiving an already-archived environment emits nothing. |
| `environment.deleted` | Environment deleted, including delete of an already-archived one. No object left to
fetch; treat the event itself as final |
| `memory_store.created` | Memory store created -- by you, or by an Anthropic-operated process that clones
one of your stores |
| `memory_store.archived` | Memory store archived. Re-archiving an already-archived store emits nothing. |
| `memory_store.deleted` | Memory store deleted, including delete of an already-archived one. Cascades to its
memories and versions **without** per-memory events -- this single event is the signal. No object left to
fetch; treat it as final |

> **There is deliberately no `memory_store.updated`.** Individual memories and memory versions emit no
webhook events at all, and neither do an environment's self-hosted work items. If you need per-memory change
tracking, poll the memory-versions endpoints (`shared/managed-agents-memory.md`).

> These are **webhook** `data.type` values -- a separate namespace from SSE event types
(`session.status_idle`, `span.outcome_evaluation_end`, etc. in `shared/managed-agents-events.md`). Don't
reuse SSE constants in webhook handlers.

---

## Delivery behavior & pitfalls

- **Duplicates.** An endpoint can receive the same event more than once; every attempt carries the same
top-level `event.id` (= the `webhook-id` header). Dedupe on it.
- **Subscription scope.** An event reaches only endpoints subscribed to its type **at the moment it is
emitted**. An event emitted while nothing was subscribed is never delivered, and subscribing later does not
backfill -- subscribe before you need the type.
- **No ordering guarantee.** Events are not delivered in occurrence order: `session.status_idled` may arrive
before `session.outcome_evaluation_ended`, and a `.deleted` can arrive before the `.archived` for the same
resource. **Drive state from the resource you fetch, not from arrival order.**
- **Retries: up to three attempts** per endpoint per event, with jittered exponential backoff between 5 and
120 seconds. A response that triggers auto-disable is never retried. **After the last attempt fails the event
is dropped** -- not queued, and with no signal that it was lost. Webhooks are not a durable log: if you must
observe every transition, reconcile by listing or fetching the resource.
- **`webhook-timestamp` is re-stamped on every attempt**, so retries don't fail the SDK's five-minute
freshness check. It times the *delivery attempt*; use the payload's `created_at` for when the event occurred.
- **Auto-disable -- three triggers**, each setting `disabled_reason`, all reversible from Console (events
emitted while disabled are **not** replayed):
  - A `3xx` response. Redirects are never followed; disables immediately, on the first attempt. Reason:
`auto-disabled: endpoint URL returned a redirect (3xx)`.
  - The URL resolves to a non-public IP at connect time. Disables immediately. Reason: `auto-disabled:
endpoint URL resolved to an invalid address`.
  - Continuous failure for a sustained period. Reason: `auto-disabled after sustained delivery failures`.
**The trigger is duration, not a delivery count** -- a single `2xx` resets the window, so one flaky event
can't disable the endpoint.
- **Thin payload is intentional.** Don't expect `stop_reason` (list the session's events for that -- the
session object has no `stop_reason` field), `outcome_evaluations`, credential secrets, etc. on the webhook
body -- fetch the resource.
</doc>

<doc path="shared/model-migration.md">
# Model Migration Guide

> **If you arrived via `/claude-api migrate`:** this is the right file. Execute the steps below in order --
do not summarize them back to the user. Start with Step 0 (confirm scope) before touching any file.
```

```
How to move existing code to newer Claude models. Covers breaking changes, deprecated parameters, and drop-in
replacements for retired models.

For the latest, authoritative version (with code samples in every supported language), WebFetch the
**Migration Guide** URL from `shared/live-sources.md`. Use this file for the consolidated, skill-resident
reference; fall back to the live docs whenever a model launch or breaking change may have shifted the picture.

**This file is large.** Use the section names below to jump (or `Grep` this file for the heading text). Read
Step 0 and Step 1 first -- they apply to every migration. Then read only the per-target section for the model
you are migrating to.

| Section | When you need it |
|---|---|
| Step 0: Confirm the migration scope | Always -- before any edits |
| Step 1: Classify each file | Always -- decides whether to swap, add-alongside, or skip |
| Per-SDK Syntax Reference | Translate the Python examples in this guide to TypeScript / Go / Ruby / Java /
C# / PHP |
| Destination Models / Retired Model Replacements | Picking a target model |
| Breaking Changes by Source Model | Migrating to Opus 4.6 / Sonnet 4.6 |
| Migrating to Opus 4.7 | Migrating to Opus 4.7 (breaking changes, silent defaults, behavioral shifts) |
| Opus 4.7 Migration Checklist | The required vs optional items for 4.7, tagged `[BLOCKS]` / `[TUNE]` |
| Migrating to Opus 4.8 | Migrating to Opus 4.8 (no new breaking changes; mid-session system prompts;
behavioral re-tuning) |
| Opus 4.8 Migration Checklist | The required vs optional items for 4.8, tagged `[BLOCKS]` / `[TUNE]` |
| Migrating to Claude Opus 5 | Migrating Opus 4.8 -> Claude Opus 5 (thinking-disabled effort-gated;
mid-conversation tool changes; per-turn effort and task budget; verbosity, over-verification, and scope
re-tuning) |
| Claude Opus 5 Migration Checklist | The required vs optional items for Claude Opus 5, tagged `[BLOCKS]` /
`[TUNE]` |
| Migrating to Claude Sonnet 5 | Migrating Sonnet 4.6 -> Claude Sonnet 5 (adaptive thinking on by default;
non-default sampling params 400; new tokenizer; `xhigh` effort for coding/agentic; high-res vision;
behavioral re-tuning) |
| Claude Sonnet 5 Migration Checklist | The required vs optional items, tagged `[BLOCKS]` / `[TUNE]` |
| Migrating to Claude Fable 5 | Migrating to Claude Fable 5 or Claude Mythos 5 (always-on thinking, raw chain
of thought never returned, refusal handling, data retention, behavioral shifts + prompting guidance) |
| Claude Fable 5 Migration Checklist | The required vs optional items for Claude Fable 5, tagged `[BLOCKS]` /
`[TUNE]` |
| Verify the Migration | After edits -- runtime spot-check |

**TL;DR:** Change the model ID string. If you were using `budget_tokens`, switch to `thinking: {type:
"adaptive"}`. If you were using assistant prefills, they 400 on both Opus 4.6 and Sonnet 4.6 -- switch to one
of the prefill replacements (most often `output_config.format`; see the table in Breaking Changes by Source
Model). If you're moving from Sonnet 4.5 to Sonnet 4.6, set `effort` explicitly -- 4.6 defaults to `high`.
Remove the `effort-2025-11-24` and `fine-grained-tool-streaming-2025-05-14` beta headers (GA on 4.6); remove
`interleaved-thinking-2025-05-14` once you're on adaptive thinking (keep it only while using the transitional
`budget_tokens` escape hatch). Then drop back from `client.beta.messages.create` to `client.messages.create`.
Dial back any aggressive "CRITICAL: YOU MUST" tool instructions; 4.6 follows the system prompt much more
closely.

---

## Step 0: Confirm the migration scope

**Before any Write, Edit, or MultiEdit call, confirm the scope.** If the user's request does not explicitly
name a single file, a specific directory, or an explicit file list, **ask first -- do not start editing**.
This is non-negotiable: even imperative-sounding requests like "migrate my codebase", "move my project to X",
"upgrade to Sonnet 4.6", or bare "migrate to Opus 4.7" leave the scope ambiguous and require a clarifying
question. Phrases like "my project", "my code", "my codebase", "the whole thing", "everywhere", or "across
the repo" are **ambiguous, not directive** -- they tell you *what* to do but not *where*. Ask before doing.

Offer the common scopes explicitly and wait for the answer before touching any file:

1. The entire working directory
2. A specific subdirectory (e.g. `src/`, `app/`, `services/billing/`)
3. A specific file or a list of files

Surface this as a single clarifying question so the user can answer in one turn. **Proceed without asking
only when the scope is already unambiguous** -- the user named an exact file ("migrate `extract.py` to Sonnet
4.6"), pointed at a specific directory ("migrate everything under `services/billing/` to Opus 4.6"), listed
```

specific files ("update `a.py` and `b.py`"), or already answered the scope question in an earlier turn. If you can answer the question "which files is this change going to touch?" with a precise list from the prompt alone, proceed. If not, ask.

Worked example. If the user says *"Move my project to Opus 4.6. I want adaptive thinking everywhere it makes sense."* you do not know whether "my project" means the whole working directory, just `src/`, just the production code, or something else -- the `everywhere` makes the intent clear (update every call site *within scope*) but the scope itself is still not defined. Do not start editing. Respond with:

> Before I start editing, can you confirm the scope? I can migrate:
> 1. Every `.py` file in the working directory
> 2. Just the files under `src/` (production code)
> 3. A specific subdirectory or list of files you name
>
> Which one?

Then wait for the answer. The same applies to *"Migrate to Opus 4.7"* and bare *"Help me upgrade to Sonnet 4.6"* -- ask before editing.

Sizing the scope question (large repos). Before asking, get a per-directory count so the user can pick concretely:

```sh
rg -l "<old-model-id>" --type-not md | cut -d/ -f1 | sort | uniq -c | sort -rn
```

Present the breakdown in your scope question (e.g. *"Found 217 references across 3 directories: api/ (130), api-go/ (62), routing/ (25). Which to migrate?"*). Also confirm `git status` is clean before surveying -- unexpected modifications mean a concurrent process; stop and investigate before proceeding.

Step 1: Classify each file

Not every file that contains the old model ID is a **caller** of the API. Before editing, classify each file into one of these buckets -- the right action differs:

#	Bucket	What it looks like	Action
1	**Calls the API/SDK**	`client.messages.create(model=...)`, `anthropic.Anthropic()`, request payloads	Swap the model ID **and** apply the breaking-change checklist for the target version (below).
2	**Defines or serves the model**	Model registries, OpenAPI specs, routing/queue configs, model-policy enums, generated catalogs	The old entry **stays** (the model is still served). Ask whether to (a) add the new model alongside, (b) leave alone, or (c) retire the old model -- never blind-replace. **If you can't ask, default to (a): add the new model alongside and flag it** -- replacing would de-register a model that's still in production.
3	**References the ID as an opaque string**	UI fallback constants, capability-gate substring checks, generic test fixtures, label parsers, env defaults	Usually swap the string and verify any parser/regex/substring match handles the new ID -- but check the sub-cases below first.
4	**Suffixed variant ID**	`claude-<model>-<suffix>` like `-fast`, `-1024k`, `-200k`, `[1m]`, dated snapshots	These are deployment/routing identifiers, not the public model ID. **Do not assume a new-model equivalent exists.** Verify in the registry first; if absent, leave the string alone and flag it. **Exception: `-fast` strings (e.g. `claude-opus-4-6-fast`) are handled by the Fast Mode section below**, which rewrites them to Opus 4.8 plus `speed="fast"` and the `fast-mode-2026-02-01` beta rather than leaving them in place.

Bucket 3 sub-cases -- before swapping a string reference, check:

- **Capability gate** (e.g. `if 'opus-4-6' in model_id:` enables a feature) -> **add the new ID alongside**, don't replace. The old model is still served and still has the capability, so replacing would silently disable the feature for any old-model traffic that still flows through. If you know no old-model traffic will hit this gate (single-caller codebase fully migrating), replacing is fine; if unsure, add alongside.
- **Registry-assert test** (e.g. `assert "claude-X" in supported_models`, `test_X_has_N_clusters`) -> **add an assertion for the new model alongside; keep the old one.** The old model is still served, so its assertion stays valid -- but the registry should also include the new model, so assert that too. Heuristic: if the test references multiple model versions in a list, it's a registry test; if one model in a struct compared only to itself, it's a generic fixture.
- **Frozen / generated snapshot** -> **regenerate**, don't hand-edit.
- **Coupled to a definer** (e.g. an integration test that passes model authorization via a shared `conftest` seed list, or asserts on a billing-tier / rate-limit-group enum or a generated SKU/pricing catalog) ->

```
**verify the definer has a new-model entry first.** If not, add a seed entry (reusing the nearest existing
tier as a placeholder); if you can't confidently do that, ask the user how to populate the definer. **Do not
skip the test.** Swapping without populating the definer will make the test fail at runtime.

When migrating tests specifically: breaking parameters (`temperature`, `top_p`, `budget_tokens`) are usually
absent -- test fixtures rarely set sampling params on placeholder models. The breaking-change scan is still
required, but expect mostly clean results.

**Find intentionally-flagged sync points first.** Many codebases tag spots that must change at every model
launch with comment markers like `MODEL LAUNCH`, `KEEP IN SYNC`, `@model-update`, or similar. Grep for
whatever convention the repo uses *before* the broad model-ID grep -- those markers point at the load-bearing
changes.

---

## Per-SDK Syntax Reference

Code examples in this guide are Python. **The same fields exist in every official Anthropic SDK** --
Stainless generates all 7 from the same OpenAPI spec, so JSON field names map 1:1 with only case-convention
differences. Use the rows below to translate the Python examples to the SDK you are migrating.

> **Verify type and method names against the SDK source before writing them into customer code.** WebFetch
the relevant repository from the SDK source-code table in `shared/live-sources.md` (one row per SDK) and
confirm the exact symbol -- particularly for typed SDKs (Go, Java, C#) where union/builder names can differ
from the JSON shape. Do not guess type names that aren't in the table below or in
`<lang>/claude-api/README.md`.

### `thinking` -- `budget_tokens` -> adaptive

| SDK | Before | After |
|---|---|---|
| Python | `thinking={"type": "enabled", "budget_tokens": N}` | `thinking={"type": "adaptive"}` |
| TypeScript | `thinking: { type: 'enabled', budget_tokens: N }` | `thinking: { type: 'adaptive' }` |
| Go | `Thinking: anthropic.ThinkingConfigParamOfEnabled(N)` | `Thinking:
anthropic.ThinkingConfigParamUnion{OfAdaptive: &anthropic.ThinkingConfigAdaptiveParam{}}` |
| Ruby | `thinking: { type: "enabled", budget_tokens: N }` | `thinking: { type: "adaptive" }` |
| Java | `.thinking(ThinkingConfigEnabled.builder().budgetTokens(N).build())` |
`.thinking(ThinkingConfigAdaptive.builder().build())` |
| C# | `Thinking = new ThinkingConfigEnabled { BudgetTokens = N }` | `Thinking = new
ThinkingConfigAdaptive()` |
| PHP | `thinking: ['type' => 'enabled', 'budget_tokens' => N]` | `thinking: ['type' => 'adaptive']` |

### Sampling parameters -- `temperature` / `top_p` / `top_k`

(Remove the field entirely on Opus 4.7; on Claude 4.x keep at most one of `temperature` or `top_p`.)

| SDK | Field(s) to remove |
|---|---|
| Python | `temperature=...`, `top_p=...`, `top_k=...` |
| TypeScript | `temperature: ...`, `top_p: ...`, `top_k: ...` |
| Go | `Temperature: anthropic.Float(...)`, `TopP: anthropic.Float(...)`, `TopK: anthropic.Int(...)` |
| Ruby | `temperature: ...`, `top_p: ...`, `top_k: ...` |
| Java | `.temperature(...)`, `.topP(...)`, `.topK(...)` |
| C# | `Temperature = ...`, `TopP = ...`, `TopK = ...` |
| PHP | `temperature: ...`, `topP: ...`, `topK: ...` |

### Prefill replacement -- structured outputs via `output_config.format`

| SDK | Remove (last assistant turn) | Add |
|---|---|---|
| Python | `{"role": "assistant", "content": "..."}` | `output_config={"format": {"type": "json_schema",
"schema": SCHEMA}}` |
| TypeScript | `{ role: 'assistant', content: '...' }` | `output_config: { format: { type: 'json_schema',
schema: SCHEMA } }` |
| Go | trailing `anthropic.MessageParam{Role: "assistant", ...}` | `OutputConfig:
anthropic.OutputConfigParam{Format: anthropic.JSONOutputFormatParam{...}}` |
| Ruby | `{ role: "assistant", content: "..." }` | `output_config: { format: { type: "json_schema", schema:
SCHEMA } }` |
```

```
| Java | trailing `Message.builder().role(ASSISTANT)...` |
`.outputConfig(OutputConfig.builder().format(JsonOutputFormat.builder()...build()).build())` |
| C# | trailing `new Message { Role = "assistant", ... }` | `OutputConfig = new OutputConfig { Format = new
JsonOutputFormat { ... } }` |
| PHP | trailing `['role' => 'assistant', 'content' => '...']` | `outputConfig: ['format' => ['type' =>
'json_schema', 'schema' => $SCHEMA]]` |

### `thinking.display` -- opt back into summarized reasoning (Opus 4.7)

| SDK | Add |
|---|---|
| Python | `thinking={"type": "adaptive", "display": "summarized"}` |
| TypeScript | `thinking: { type: 'adaptive', display: 'summarized' }` |
| Go | `Thinking: anthropic.ThinkingConfigParamUnion{OfAdaptive:
&anthropic.ThinkingConfigAdaptiveParam{Display: anthropic.ThinkingConfigAdaptiveDisplaySummarized}}` |
| Ruby | `thinking: { type: "adaptive", display: "summarized" }` (or `display_:` when constructing the model
class directly) |
| Java |
`.thinking(ThinkingConfigAdaptive.builder().display(ThinkingConfigAdaptive.Display.SUMMARIZED).build())` |
| C# | `Thinking = new ThinkingConfigAdaptive { Display = Display.Summarized }` |
| PHP | `thinking: ['type' => 'adaptive', 'display' => 'summarized']` |

For any field not in these tables, the JSON key in the Python example translates directly: `snake_case` for
Python/TypeScript/Ruby, `camelCase` named args for PHP, `PascalCase` struct fields for Go/C#, `camelCase`
builder methods for Java.

---

## Explain every change you make

Migration edits often look arbitrary to a user who hasn't read the release notes -- a removed `temperature`,
a deleted prefill, a rewritten system-prompt sentence. **For each edit, tell the user what you changed and
why**, tied to the specific API or behavioral change that motivates it. Do this in your summary as you work,
not just at the end.

Be especially explicit about **system-prompt edits**. Users are rightly protective of their prompts, and
prompt-tuning changes are judgment calls (not hard API requirements). For any prompt edit:

- Quote the before and after text.
- State the behavioral shift that motivates it (e.g. *"Opus 4.7 calibrates response length to task
complexity, so I added an explicit length instruction"*, or *"4.6 follows instructions more literally, so
'CRITICAL: YOU MUST use the search tool' will now overtrigger -- softened to 'Use the search tool when...'"*).
- Make clear which prompt edits are **optional tuning** (tone, length, subagent guidance) versus which code
edits are **required to avoid a 400** (sampling params, `budget_tokens`, prefills). Never present an optional
prompt change as mandatory.

If you're applying several prompt-tuning edits at once, offer them as a short list the user can accept or
decline item-by-item rather than silently rewriting their system prompt.

---

## Before You Migrate

1. **Confirm the target model ID.** Use only the exact strings from `shared/models.md` -- do not append date
suffixes to aliases (`claude-opus-4-6`, not `claude-opus-4-6-20251101`). Guessing an ID will 404.
2. **Check which features your code uses** with this checklist:
   - `thinking: {type: "enabled", budget_tokens: N}` -> migrate to adaptive thinking on Opus 4.6 / Sonnet 4.6
(still functional but deprecated)
   - Assistant-turn prefills (`messages` ending with `role: "assistant"`) -> must change on Opus 4.6 / Sonnet
4.6 (returns 400)
   - `output_format` parameter on `messages.create()` -> must change on all models (deprecated API-wide)
   - `max_tokens > ~16000` -> must stream on any model (above ~16K risks SDK HTTP timeouts). When streaming,
every current model reaches 128K except Haiku 4.5, which caps at 64K
   - Beta headers `effort-2025-11-24`, `fine-grained-tool-streaming-2025-05-14`,
`interleaved-thinking-2025-05-14` -> GA on 4.6, remove them and switch from `client.beta.messages.create` to
`client.messages.create`
   - Moving Sonnet 4.5 -> Sonnet 4.6 with no `effort` set -> 4.6 defaults to `high`, which may change your
latency/cost profile
   - System prompts with `CRITICAL`, `MUST`, `If in doubt, use X` language -> likely to overtrigger on 4.6
(see Prompt-Behavior Changes)
```

```
   - Coming from 3.x / 4.0 / 4.1: also check sampling params (`temperature` + `top_p`), tool versions
(`text_editor_20250728`), `refusal` + `model_context_window_exceeded` stop reasons, trailing-newline
tool-param handling
3. **Test on a single request first.** Run one call against the new model, inspect the response, then roll
out.

---

## Destination Models (recommended targets)

| If you're on...                         | Migrate to         | Why
|
| --------------------------------------- | ------------------ |
------------------------------------------------ |
| Claude Mythos Preview (`claude-mythos-preview`) | `claude-mythos-5` (Project Glasswing successor) or
`claude-fable-5` (GA) | Same tokenizer family -- mostly a model-ID swap; remove `thinking` config and
prefill; see Migrating to Claude Fable 5 |
| Opus 4.8                                | `claude-opus-5` | The current Opus. Two breaking changes (thinking
on by default; disabling thinking capped at `high` effort) plus prompt re-tuning -- see Migrating to Claude
Opus 5 |
| Opus 4.7                                | `claude-opus-5` | Apply the Opus 4.8 section (prompt re-tuning, no
new breaking changes), then the Claude Opus 5 section |
| Opus 4.6                                | `claude-opus-5` | Apply the Opus 4.7 breaking changes, then 4.8
re-tuning, then the Claude Opus 5 section |
| Opus 4.0 / 4.1 / 4.5 / Opus 3           | `claude-opus-5` | Apply 4.6 -> 4.7 -> 4.8 -> Claude Opus 5 in order
(adaptive thinking, drop sampling params, then re-tune) |
| Sonnet 4.6                              | `claude-sonnet-5` | Near-Opus quality on agentic and coding work at
Sonnet cost; adaptive thinking on by default; see Migrating to Claude Sonnet 5 |
| Sonnet 4.0 / 4.5 / 3.7 / 3.5            | `claude-sonnet-5` | Apply the Sonnet 4.6 changes first, then the
Claude Sonnet 5 section |
| Haiku 3 / 3.5                           | `claude-haiku-4-5` | Fastest and most cost-effective
|

Default to the latest Opus for the caller's tier unless they explicitly chose otherwise. The Opus migrations
layer: if you're on Opus 4.6 or older, apply each version's section in order up to your target (e.g. 4.5 ->
4.8 means the 4.6, 4.7, and 4.8 sections in sequence). A 4.7 -> 4.8 move has no new breaking changes -- see
Migrating to Opus 4.8 below.

---

## Retired Model Replacements

These models return 404 -- update immediately:

| Retired model                | Retired       | Drop-in replacement  |
| ---------------------------- | ------------- | -------------------- |
| `claude-3-7-sonnet-20250219`  | Feb 19, 2026  | `claude-sonnet-5` |
| `claude-3-5-haiku-20241022`   | Feb 19, 2026  | `claude-haiku-4-5`   |
| `claude-3-opus-20240229`      | Jan 5, 2026   | `claude-opus-4-8`    |
| `claude-3-5-sonnet-20241022`  | Oct 28, 2025  | `claude-sonnet-5` |
| `claude-3-5-sonnet-20240620`  | Oct 28, 2025  | `claude-sonnet-5` |
| `claude-3-sonnet-20240229`    | Jul 21, 2025  | `claude-sonnet-5` |
| `claude-2.1`, `claude-2.0`    | Jul 21, 2025  | `claude-sonnet-5` |

## Deprecated Models (retiring soon)

| Model                        | Retires       | Replacement          |
| ---------------------------- | ------------- | -------------------- |
| `claude-3-haiku-20240307`     | Apr 19, 2026  | `claude-haiku-4-5`   |
| `claude-opus-4-20250514`      | June 15, 2026 | `claude-opus-4-8`    |
| `claude-sonnet-4-20250514`    | June 15, 2026 | `claude-sonnet-5` |

---

## Breaking Changes by Source Model

### Migrating from Sonnet 4.5 to Sonnet 4.6 (effort default change)

Sonnet 4.5 had no `effort` parameter; Sonnet 4.6 defaults to `high`. If you just switch the model string and
do nothing else, you may see noticeably higher latency and token usage. Set `effort` explicitly.
```

```
**Recommended starting points:**

| Workload                                          | Start at       | Notes
|
| ------------------------------------------------- | -------------- |
---------------------------------------------------------------------------------------------------- |
| Chat, classification, content generation          | `low`          | With `thinking: {"type": "disabled"}`
you'll see similar or better performance vs. Sonnet 4.5 no-thinking |
| Most applications (balanced)                      | `medium`       | The default sweet spot for quality vs.
cost                                                                 |
| Agentic coding, tool-heavy workflows              | `medium`       | Pair with adaptive thinking and a
generous `max_tokens` (up to 128K with streaming -- Sonnet 4.6's ceiling) |
| Autonomous multi-step agents, long-horizon loops  | `high`         | Scale down to `medium` if
latency/tokens become a concern                                      |
| Computer-use agents                               | `high` + adaptive | Sonnet 4.6's best computer-use
accuracy is on adaptive + high                                       |

For non-thinking chat workloads specifically:

```python
client.messages.create(
    model="claude-sonnet-4-6",
    max_tokens=8192,
    thinking={"type": "disabled"},
    output_config={"effort": "low"},
    messages=[{"role": "user", "content": "..."}],
)
```

When to use Opus 4.6 instead: hardest and longest-horizon problems -- large code migrations, deep
research, extended autonomous work. Sonnet 4.6 wins on fast turnaround and cost efficiency.

Migrating to Opus 4.6 / Sonnet 4.6 (from any older model)

1. Manual extended thinking is deprecated -- use adaptive thinking.

`thinking: {type: "enabled", budget_tokens: N}` (manual extended thinking with a fixed token budget) is
deprecated on Opus 4.6 and Sonnet 4.6. Replace it with `thinking: {type: "adaptive"}`, which lets Claude
decide when and how much to think. Adaptive thinking also enables interleaved thinking automatically (no beta
header needed).

```python
# Old (still works on older models, deprecated on 4.6)
response = client.messages.create(
    model="claude-sonnet-4-5",
    max_tokens=16000,
    thinking={"type": "enabled", "budget_tokens": 8000},
    messages=[...]
)

# New (Opus 4.6 / Sonnet 4.6)
response = client.messages.create(
    model="claude-opus-4-6",  # or "claude-sonnet-4-6"
    max_tokens=16000,
    thinking={"type": "adaptive"},
    output_config={"effort": "high"},  # optional: low | medium | high | max
    messages=[...]
)
```

Adaptive thinking is the long-term target, and on internal evaluations it outperforms manual extended
thinking. Move when you can.

Transitional escape hatch: manual extended thinking is still *functional* on Opus 4.6 and Sonnet 4.6
(deprecated, will be removed in a future release). If you need a hard ceiling while migrating -- for example,
to bound token spend on a runaway workload before you've tuned `effort` -- you can keep `budget_tokens`
around alongside an explicit `effort` value, then remove it in a follow-up. `budget_tokens` must be strictly
less than `max_tokens`:
```

```python
# Transitional only -- deprecated, plan to remove
client.messages.create(
    model="claude-sonnet-4-6",
    max_tokens=16384,
    thinking={"type": "enabled", "budget_tokens": 8192},  # must be < max_tokens
    output_config={"effort": "medium"},
    messages=[...],
)
```

If the user asks for a "thinking budget" on 4.6, the preferred answer is `effort` -- use `low`, `medium`, `high`, or `max` rather than a token count.

2. Effort parameter (Opus 4.5, Opus 4.6, Sonnet 4.6 only).

Controls thinking depth and overall token spend. Goes inside `output_config`, not top-level. Default is `high`. `max` is supported on Fable 5, Opus 4.6 and later, Sonnet 5, and Sonnet 4.6 -- it errors on Sonnet 4.5 and Haiku 4.5.

```python
output_config={"effort": "medium"}  # often the best cost / quality balance
```

Migrating to the 4.6 family (Opus 4.6 and Sonnet 4.6)

3. Assistant-turn prefills return 400 (Opus 4.6 and Sonnet 4.6).

Prefilled responses on the final assistant turn are no longer supported on either Opus 4.6 or Sonnet 4.6 -- both return a 400. Adding assistant messages *elsewhere* in the conversation (e.g., for few-shot examples) still works. Pick the replacement that matches what the prefill was doing:

Prefill was used for	Replacement
Forcing JSON / YAML / schema output	`output_config.format` with a `json_schema` -- see example below
Forcing a classification label	Tool with an enum field containing valid labels, or structured outputs
Skipping preambles (`Here is the summary:\n`)	System prompt instruction: *"Respond directly without preamble. Do not start with phrases like 'Here is...' or 'Based on...'."*
Steering around bad refusals	Usually no longer needed -- 4.6 refuses far more appropriately. Plain user-turn prompting is sufficient.
Continuing an interrupted response	Move continuation into the user turn: *"Your previous response was interrupted and ended with `[last text]`. Continue from there."*
Injecting reminders / context hydration	Inject into the user turn instead. For complex agent harnesses, expose context via a tool call or during compaction.

```python
# Old (fails on Opus 4.6 / Sonnet 4.6) -- prefill forcing JSON shape
messages=[
    {"role": "user", "content": "Extract the name."},
    {"role": "assistant", "content": "{\"name\": \""},
]

# New -- structured outputs replace the prefill
response = client.messages.create(
    model="claude-opus-4-6",
    max_tokens=1024,
    output_config={"format": {"type": "json_schema", "schema": {...}}},
    messages=[{"role": "user", "content": "Extract the name."}],
)
```

4. Stream for `max_tokens > ~16K` (all models); only Haiku 4.5 caps lower, at 64K.

Non-streaming requests hit SDK HTTP timeouts at high `max_tokens`, regardless of model -- stream for anything above ~16K output. The streamable ceiling is 128K for every current model except Haiku 4.5, which caps at 64K.

```python
with client.messages.stream(model="claude-opus-4-6", max_tokens=64000, ...) as stream:
    message = stream.get_final_message()
```

5. Tool-call JSON escaping may differ (Opus 4.6 and Sonnet 4.6).

Both 4.6 models can produce tool call `input` fields with Unicode or forward-slash escaping. Always parse with `json.loads()` / `JSON.parse()` -- never raw-string-match the serialized input.

All models

6. `output_format` -> `output_config.format` (API-wide).

The old top-level `output_format` parameter on `messages.create()` is deprecated. Use `output_config.format` instead. This is not 4.6-specific -- applies to every model.

Beta Headers to Remove on 4.6

Several beta headers that were required on 4.5 are now GA on 4.6 and should be removed. Leaving them in is harmless but misleading; removing them also lets you move from `client.beta.messages.create(...)` back to `client.messages.create(...)`.

Header	Status on 4.6	Action
`effort-2025-11-24`	Effort parameter is GA	Remove
`fine-grained-tool-streaming-2025-05-14`	GA	Remove
`interleaved-thinking-2025-05-14`	Adaptive thinking enables interleaved thinking automatically	Remove when using adaptive thinking; still functional on Sonnet 4.6 *with* manual extended thinking, but that path is deprecated
`token-efficient-tools-2025-02-19`	Built in to all Claude 4+ models	Remove (no effect)
`output-128k-2025-02-19`	Built in to Claude 4+ models	Remove (no effect)

Once you remove all of these and finish moving to adaptive thinking, you can switch the SDK call site from the beta namespace back to the regular one:

```python
# Before
response = client.beta.messages.create(
    model="claude-opus-4-5",
    betas=["interleaved-thinking-2025-05-14", "effort-2025-11-24"],
    ...
)

# After
response = client.messages.create(
    model="claude-opus-4-6",
    thinking={"type": "adaptive"},
    output_config={"effort": "high"},
    ...
)
```

Additional Changes When Coming from 3.x / 4.0 / 4.1 -> 4.6

If you're jumping from Opus 4.1, Sonnet 4, Sonnet 3.7, or an older Claude 3.x model directly to 4.6, apply everything above *plus* the items in this section. Users already on Opus 4.5 / Sonnet 4.5 can skip this.

1. Sampling parameters: `temperature` OR `top_p`, not both.

Passing both will error on every Claude 4+ model:

```python
# Old (3.x only -- errors on 4+)
client.messages.create(temperature=0.7, top_p=0.9, ...)

# New
client.messages.create(temperature=0.7, ...)  # or top_p, not both
```

2. Update tool versions.

Legacy tool versions are not supported on 4+. **Both the `type` and the `name` field change** -- `text_editor_20250728` and `str_replace_based_edit_tool` are a pair; updating one without the other 400s. Also remove the `undo_edit` command from your text-editor integration:

Old	New
`text_editor_20250124` + `str_replace_editor`	`text_editor_20250728` + `str_replace_based_edit_tool`
`code_execution_*` (earlier versions)	`code_execution_20260521`
`undo_edit` command	*(no longer supported -- delete call sites)*

```python
# Before
tools = [{"type": "text_editor_20250124", "name": "str_replace_editor"}]

# After -- BOTH fields change
tools = [{"type": "text_editor_20250728", "name": "str_replace_based_edit_tool"}]
```

3. Handle the `refusal` stop reason.

Claude 4+ can return `stop_reason: "refusal"` on the response. If your code only handles `end_turn` / `tool_use` / `max_tokens`, add a branch:

```python
if response.stop_reason == "refusal":
    # Surface the refusal to the user; do not retry with the same prompt
    ...
```

4. Handle the `model_context_window_exceeded` stop reason (4.5+).

Distinct from `max_tokens`: it means the model hit the *context window* limit, not the requested output cap. Handle both:

```python
if response.stop_reason == "model_context_window_exceeded":
    # Context window exhausted -- compact or split the conversation
    ...
elif response.stop_reason == "max_tokens":
    # Requested output cap hit -- retry with higher max_tokens or stream
    ...
```

5. Trailing newlines preserved in tool call string parameters (4.5+).

4.5 and 4.6 preserve trailing newlines that older models stripped. If your tool implementations do exact string matching against tool-call `input` values (e.g., `if name == "foo"`), verify they still match when the model sends `"foo\n"`. Normalizing with `.rstrip()` on the receiving side is usually the simplest fix.

6. Haiku: rate limits reset between generations.

Haiku 4.5 has its own rate-limit pool separate from Haiku 3 / 3.5. If you're ramping traffic as you migrate,

```
check your tier's Haiku 4.5 limits at [API rate limits](https://platform.claude.com/docs/en/api/rate-limits)
-- a quota that comfortably served Haiku 3.5 traffic may need a tier bump for the same volume on 4.5.

---

## Prompt-Behavior Changes (Opus 4.5 / 4.6, Sonnet 4.6)

These don't break your code, but prompts that worked on 4.5-and-earlier may over- or under-trigger on 4.6.
Tune as needed. For a standing, model-general audit of dated prompt text beyond this migration -- skills and
tool descriptions included -- read `shared/prompt-audit.md` (or invoke `/claude-api prompt-audit`).

**1. Aggressive instructions cause overtriggering.** Opus 4.5 and 4.6 follow the system prompt much more
closely than earlier models. Prompts written to *overcome* the old reluctance are now too aggressive:

| Before (worked on 4.0 / 4.5)                | After (use on 4.6)                        |
| ------------------------------------------- | ----------------------------------------- |
| `CRITICAL: You MUST use this tool when...`  | `Use this tool when...`                   |
| `Default to using [tool]`                   | `Use [tool] when it would improve X`      |
| `If in doubt, use [tool]`                   | *(delete -- no longer needed)*             |

If the model is now overtriggering a tool or skill, the fix is almost always to dial back the language, not
to add more guardrails.

**2. Overthinking and excessive exploration (Opus 4.6).** At higher `effort` settings, Opus 4.6 explores more
before answering. If that burns too many thinking tokens, lower `effort` first (`medium` is often the sweet
spot) before adding prose instructions to constrain reasoning.

**3. Overeager subagent spawning (Opus 4.6).** Opus 4.6 has a strong preference for delegating to subagents.
If you see it spawning a subagent for something a direct `grep` or `read` would solve, add guidance: *"Use
subagents only for parallel or independent workstreams. For single-file reads or sequential operations, work
directly."*

**4. Overengineering (Opus 4.5 / 4.6).** Both models may add extra files, abstractions, or defensive error
handling beyond what was asked. If you want minimal changes, prompt for it explicitly: *"Only make changes
directly requested. Don't add helpers, abstractions, or error handling for scenarios that can't happen."*

**5. LaTeX math output (Opus 4.6).** Opus 4.6 defaults to LaTeX (`\frac{}{}`, `$...$`) for math and technical
content. If you need plain text, instruct it explicitly: *"Format all math as plain text -- no LaTeX, no `$`,
no `\frac{}{}`. Use `/` for division and `^` for exponents."*

**6. Skipped verbal summaries (4.6 family).** The 4.6 models are more concise and may skip the summary
paragraph after a tool call, jumping straight to the next action. If you rely on those summaries for
visibility, add: *"After completing a task that involves tool use, provide a brief summary of what you did."*

**7. "Think" as a trigger word (Opus 4.5 with thinking disabled).** When `thinking` is off, Opus 4.5 is
particularly sensitive to the word *think* and may reason more than you want. Use `consider`, `evaluate`, or
`reason through` instead.

---

## Model-ID Rename Quick Reference

| Old string (migration source)  | New string         |
| ------------------------------ | ------------------ |
| `claude-opus-4-8`              | `claude-opus-5`     |
| `claude-opus-4-7`              | `claude-opus-5`     |
| `claude-opus-4-6`              | `claude-opus-5`     |
| `claude-opus-4-5`              | `claude-opus-5`     |
| `claude-opus-4-1`              | `claude-opus-5`     |
| `claude-opus-4-0`              | `claude-opus-5`     |
| `claude-mythos-preview`        | `claude-mythos-5` (Project Glasswing) or `claude-fable-5` |
| `claude-sonnet-4-6`            | `claude-sonnet-5`|
| `claude-sonnet-4-5`            | `claude-sonnet-5`|
| `claude-sonnet-4-0`            | `claude-sonnet-5`|

Older aliases (`claude-opus-4-7`, `claude-opus-4-6`, `claude-opus-4-5`, `claude-sonnet-4-6`,
`claude-sonnet-4-5`, etc.) are still active and can be pinned if you need time before upgrading -- see
`shared/models.md` for the full legacy list.

### Amazon Bedrock model IDs
```

```
If the code uses the `AnthropicBedrockMantle` client (Python `anthropic[bedrock]`, TypeScript
`@anthropic-ai/bedrock-sdk`, Java `BedrockMantleBackend`, Go `bedrock.NewMantleClient`, etc.) or targets
`https://bedrock-mantle.{region}.api.aws/anthropic`, it is running on **Claude in Amazon Bedrock**. All
breaking changes in this guide apply unchanged there -- it serves the same Messages API shape -- but model
IDs carry an `anthropic.` provider prefix:

| First-party ID | Bedrock ID |
|---|---|
| `claude-opus-4-8` | `anthropic.claude-opus-4-8` |
| `claude-opus-5` | `anthropic.claude-opus-5` |
| `claude-opus-4-7` | `anthropic.claude-opus-4-7` |
| `claude-sonnet-5` | `anthropic.claude-sonnet-5` |
| `claude-haiku-4-5` | `anthropic.claude-haiku-4-5` |

When migrating a Bedrock file, apply the same rename-table row as first-party, then keep/add the `anthropic.`
prefix. Do **not** generate a first-party `claude-*` ID for a Bedrock client -- it will 400.

**Skip for Bedrock:** the `code_execution_*` tool-version checklist item and the **Task Budgets** section --
neither is available on Bedrock (see `shared/platform-availability.md` for the per-feature table). Everything
else in this guide -- `effort`, adaptive/extended thinking, `output_config.format`, `thinking.display`,
fine-grained tool streaming, token counting -- is available on Bedrock.

> **Out of scope:** the legacy Amazon Bedrock integration (`InvokeModel` / `Converse` APIs with ARN-versioned
IDs like `anthropic.claude-3-5-sonnet-20241022-v2:0`) uses a different request shape and model-ID format.
This guide does not cover it; WebFetch the Bedrock page in `shared/live-sources.md` if the user is migrating
between the two Bedrock integrations.

### Claude Platform on AWS

If the code uses `AnthropicAWS` / `AnthropicAws` / `anthropicaws.NewClient` / `AnthropicAwsClient` (or
targets `https://aws-external-anthropic.{region}.api.aws`), it is running on **Claude Platform on AWS** --
Anthropic-operated, same-day API parity. Model IDs are **bare first-party** strings; apply the rename table
above **verbatim** and every breaking-change section in this guide unchanged. There is nothing to skip. Do
**not** add an `anthropic.` prefix (that's Amazon Bedrock, a separate offering). See
`shared/claude-platform-on-aws.md` for client/auth details.

---

## Migration Checklist

Every item is tagged: **`[BLOCKS]`** items cause a 400 error, infinite loop, silent timeout, or wrong tool
selection if missed -- apply these as code edits, not as suggestions. **`[TUNE]`** items are quality/cost
adjustments.

For each file that calls `messages.create()` / equivalent SDK method:

- [ ] **[BLOCKS]** Update the `model=` string to the new alias
- [ ] **[BLOCKS]** Replace `budget_tokens` with `thinking={"type": "adaptive"}` (deprecated on Opus 4.6 /
Sonnet 4.6)
- [ ] **[BLOCKS]** Move `format` from top-level `output_format` into `output_config.format`
- [ ] **[BLOCKS]** Remove any assistant-turn prefills if targeting Opus 4.6 or Sonnet 4.6 (see the prefill
replacement table)
- [ ] **[BLOCKS]** Switch to streaming if `max_tokens > ~16000` (otherwise SDK HTTP timeout)
- [ ] **[TUNE]** Verify tool-input handling parses JSON rather than raw-string-matching the serialized input
(4.6 may escape Unicode / forward slashes differently; most SDKs already expose `block.input` as a parsed
object)
- [ ] **[TUNE]** Set `output_config={"effort": "..."}` explicitly -- especially when moving Sonnet 4.5 ->
Sonnet 4.6 (4.6 defaults to `high`)
- [ ] **[TUNE]** Remove GA beta headers: `effort-2025-11-24`, `fine-grained-tool-streaming-2025-05-14`,
`token-efficient-tools-2025-02-19`, `output-128k-2025-02-19`; remove `interleaved-thinking-2025-05-14` once
on adaptive thinking
- [ ] **[TUNE]** Switch `client.beta.messages.create(...)` -> `client.messages.create(...)` once all betas
are removed
- [ ] **[TUNE]** Review system prompt for aggressive tool language (`CRITICAL:`, `MUST`, `If in doubt`) and
dial it back

**Extra items when coming from 3.x / 4.0 / 4.1:**
- [ ] **[BLOCKS]** Remove either `temperature` or `top_p` (passing both 400s on Claude 4+)
- [ ] **[BLOCKS]** Update text-editor tool `type` to `text_editor_20250728`
```

```
- [ ] **[BLOCKS]** Update text-editor tool `name` to `str_replace_based_edit_tool` -- **changing only the
`type` and keeping `name: "str_replace_editor"` returns a 400**
- [ ] **[BLOCKS]** Update code-execution tool to `code_execution_20260521`
- [ ] **[BLOCKS]** Delete any `undo_edit` command call sites
- [ ] **[TUNE]** Add handling for `stop_reason == "refusal"`
- [ ] **[TUNE]** Add handling for `stop_reason == "model_context_window_exceeded"` (4.5+)
- [ ] **[TUNE]** Verify tool-param string matching tolerates trailing newlines (preserved on 4.5+)
- [ ] **[TUNE]** If moving to Haiku 4.5: review rate-limit tier (separate pool from Haiku 3.x)

**Verification:**
- [ ] Run one test request and inspect `response.stop_reason`, `response.usage`, and whether tool-use /
thinking behavior matches expectations

For cached prompts: the render order and hash inputs did not change, so existing `cache_control` breakpoints
keep working. However, **changing the model string invalidates the existing cache** -- the first request on
the new model will write the cache fresh.

---

## Migrating to Opus 4.7

> **Model ID `claude-opus-4-7` is authoritative as written here.** When the user asks to migrate to Opus 4.7,
write `model="claude-opus-4-7"` exactly. Do **not** WebFetch to verify -- this guide is the source of truth
for migration target IDs. The corresponding entry exists in `shared/models.md`.

Claude Opus 4.7 was Anthropic's most capable model at its launch and is now the previous-generation Opus
(Opus 4.8 is current -- see Migrating to Opus 4.8 below). It is highly autonomous and performs exceptionally
well on long-horizon agentic work, knowledge work, vision tasks, and memory tasks. This section summarizes
everything that was new at the 4.7 launch and remains the layered breaking-change path for callers coming
from Opus 4.6 or older. It is layered on top of the 4.6 migration above -- if the caller is jumping from Opus
4.5 or older, apply the 4.6 changes first, then this section, then the 4.8 section.

**TL;DR for someone already on Opus 4.6:** update the model ID to `claude-opus-4-7`, strip any remaining
`budget_tokens` and sampling parameters (both 400 on Opus 4.7), give `max_tokens` extra headroom and
re-baseline with `count_tokens()` against the new model, opt back into `thinking.display: "summarized"` if
reasoning is surfaced to users, and re-tune `effort` -- it matters more on 4.7 than on any prior Opus.

### Breaking changes (will 400 on Opus 4.7)

**Extended thinking removed.**

`thinking: {type: "enabled", budget_tokens: N}` is no longer supported on Claude Opus 4.7 or later models and
returns a 400 error. Switch to adaptive thinking (`thinking: {type: "adaptive"}`) and use the effort
parameter to control thinking depth. Adaptive thinking is **off by default** on Claude Opus 4.7: requests
with no `thinking` field run without thinking, matching Opus 4.6 behavior. Set `thinking: {type: "adaptive"}`
explicitly to enable it.

```python
# Before (Opus 4.6)
client.messages.create(
    model="claude-opus-4-6",
    max_tokens=64000,
    thinking={"type": "enabled", "budget_tokens": 32000},
    messages=[{"role": "user", "content": "..."}],
)

# After (Opus 4.7)
client.messages.create(
    model="claude-opus-4-7",
    max_tokens=64000,
    thinking={"type": "adaptive"},
    output_config={"effort": "high"},  # or "max", "xhigh", "medium", "low"
    messages=[{"role": "user", "content": "..."}],
)
```

If the caller wasn't using extended thinking, no change is required -- thinking is off by default, or can be
set explicitly with `thinking={"type": "disabled"}`.

Delete `budget_tokens` plumbing entirely. For the replacement `effort` value, see **Choosing an effort level
```

````
on Opus 4.7** below -- there is no exact 1:1 mapping from `budget_tokens`.

**Sampling parameters removed.**

The `temperature`, `top_p`, and `top_k` parameters are no longer accepted on Claude Opus 4.7. Requests that
include them return a 400 error. Remove these fields from your request payloads. Prompting is the recommended
way to guide model behavior on Claude Opus 4.7. If you were using `temperature = 0` for determinism, note
that it never guaranteed identical outputs on prior models.

```python
# Before -- errors on Opus 4.7
client.messages.create(temperature=0.7, top_p=0.9, ...)

# After
client.messages.create(...)  # no sampling params
```

- **If the intent was determinism** -- use `effort: "low"` with a tighter prompt.
- **If the intent was creative variance** -- the prompt replacement depends on the use case; **ask the user**
how they want variance elicited. If you can't ask, add a use-case-appropriate instruction along the lines of
*"choose something off-distribution and interesting"* -- e.g. for text generation, *"Vary your phrasing and
structure across responses"*; for frontend/design, use the propose-4-directions approach under **Design and
frontend coding** below.

### Choosing an effort level on Opus 4.7

`budget_tokens` controlled how much to *think*; `effort` controls how much to think *and* act, so there is no
exact 1:1 mapping. **Use `xhigh` for best results in coding and agentic use cases, and a minimum of `high`
for most intelligence-sensitive use cases.** Experiment with other levels to further tune token usage and
intelligence:

| Level | Use when | Notes |
| --- | --- | --- |
| `max` | Intelligence-demanding tasks worth testing at the ceiling | Can deliver gains in some use cases but
may show diminishing returns from increased token usage; can be prone to overthinking |
| `xhigh` | **Most coding and agentic use cases** | The best setting for these; used as the default in Claude
Code |
| `high` | Intelligence-sensitive use cases generally | Balances token usage and intelligence; recommended
minimum for most intelligence-sensitive work |
| `medium` | Cost-sensitive use cases that need to reduce token usage while trading off intelligence | |
| `low` | Short, scoped tasks and latency-sensitive workloads that are not intelligence-sensitive | |

### Silent default changes (no error, but behavior differs)

**Thinking content omitted by default.**

Thinking blocks still appear in the response stream on Claude Opus 4.7, but their `thinking` field is empty
unless you explicitly opt in. This is a silent change from Claude Opus 4.6, where the default was to return
summarized thinking text. To restore summarized thinking content on Claude Opus 4.7, set `thinking.display`
to `"summarized"`. **The block-field name is unchanged** -- it is still `block.thinking` on a `thinking`-type
block; do not rename it.

**Detect this:** any code that reads `block.thinking` (or equivalent) from a `thinking`-type block and
renders it in a UI, log, or trace. **The fix is the request parameter, not the response handling** -- add
`display: "summarized"` to the `thinking` parameter:

```python
thinking={"type": "adaptive", "display": "summarized"}  # "display" is new on Opus 4.7; values: "omitted"
(default) | "summarized"
```

The default is `"omitted"` on Claude Opus 4.7. If thinking content was never surfaced anywhere, no change
needed. If your product streams reasoning to users, the new default appears as a long pause before output
begins; set `display: "summarized"` to restore visible progress during thinking.

**Updated token counting.**

Claude Opus 4.7 and Claude Opus 4.6 count tokens differently. The same input text produces a higher token
count on Claude Opus 4.7 than on Claude Opus 4.6, and `/v1/messages/count_tokens` will return a different
number of tokens for Claude Opus 4.7 than it did for Claude Opus 4.6. The token efficiency of Claude Opus 4.7
````

can vary by workload shape. Prompting interventions, `task_budget`, and `effort` can help control costs and ensure appropriate token usage. Keep in mind that these controls may trade off model intelligence. **Update your `max_tokens` parameters to give additional headroom, including compaction triggers.** Claude Opus 4.7 provides a 1M context window at standard API pricing with no long-context premium.

What else to check:

- Client-side token estimators (tiktoken-style approximations) calibrated against 4.6
- Cost calculators that multiply tokens by a fixed per-token rate
- Rate-limit retry thresholds keyed to measured token counts

Re-baseline by re-running `client.messages.count_tokens()` against `claude-opus-4-7` on a representative sample of the caller's prompts. Do not apply a blanket multiplier. For cost-sensitive workloads, consider reducing `effort` by one level (e.g. `high` -> `medium`). For agentic loops, consider adopting Task Budgets (below).

New feature: Task Budgets (beta)

Opus 4.7 introduces **task budgets** -- tell Claude how many tokens it has for a full agentic loop (thinking + tool calls + final output). The model sees a running countdown and uses it to prioritize work and wrap up gracefully as the budget is consumed.

This is a **suggestion the model is aware of**, not a hard cap. It is distinct from `max_tokens`, which remains the enforced per-response limit and is *not* surfaced to the model. Use `task_budget` when you want the model to self-moderate; use `max_tokens` as a hard ceiling to cap usage.

Requires beta header `task-budgets-2026-03-13`:

```python
client.beta.messages.create(
    betas=["task-budgets-2026-03-13"],
    model="claude-opus-4-7",
    max_tokens=64000,
    thinking={"type": "adaptive"},
    output_config={
        "effort": "high",
        "task_budget": {"type": "tokens", "total": 128000},
    },
    messages=[...],
)
```

Set a generous budget for open-ended agentic tasks and tighten it for latency-sensitive ones. **Minimum `task_budget.total` is 20,000 tokens.** If the budget is too restrictive for the task, the model may complete it less thoroughly, referencing its budget as the constraint. **Do not add `task_budget` during a migration unless you are sure the budget value is right** -- if you can run the workload and measure, do so; otherwise ask the user for the value rather than guessing. This is the primary lever for offsetting the token-counting shift on agentic workloads.

Capability improvements

High-resolution vision. Opus 4.7 is the first Claude model with high-resolution image support. Maximum image resolution is **2576 pixels on the long edge** (up from 1568px on Opus 4.6 and prior). This unlocks gains on vision-heavy workloads, especially computer use and screenshot/artifact/document understanding. Coordinates returned by the model now map 1:1 to actual image pixels, so no scale-factor math is needed.

High-res support is **automatic on Opus 4.7** -- no beta header, no client-side opt-in required. The model accepts larger inputs and returns pixel-accurate coordinates out of the box.

Token cost. Full-resolution images on Opus 4.7 can use up to ~3x more image tokens than on prior models (up to ~4784 tokens per image, vs. the previous ~1,600-token cap). If the extra fidelity isn't needed, downsample client-side before sending to control cost -- but **do not add downsampling by default during a migration**. If you're not sure whether the pipeline needs the fidelity, ask the user rather than guessing. Use `count_tokens()` on representative images on Opus 4.7 to re-baseline before reacting to any measured cost shift.

Beyond resolution, Opus 4.7 also improves on low-level perception (pointing, measuring, counting) and natural-image bounding-box localization and detection.

Knowledge work. Meaningful gains on tasks where the model visually verifies its own output -- `.docx`

```
redlining, `.pptx` editing, and programmatic chart/figure analysis (e.g. pixel-level data transcription via
image-processing libraries). If prompts have scaffolding like *"double-check the slide layout before
returning"*, try removing it and re-baselining.

**Memory.** Opus 4.7 is better at writing and using file-system-based memory. If an agent maintains a
scratchpad, notes file, or structured memory store across turns, that agent should improve at jotting down
notes to itself and leveraging its notes in future tasks.

**User-facing progress updates.** Opus 4.7 provides more regular, higher-quality interim updates during long
agentic traces. If the system prompt has scaffolding like *"After every 3 tool calls, summarize progress"*,
try removing it to avoid excessive user-facing text. If the length or contents of Opus 4.7's updates are not
well-calibrated to your use case, explicitly describe what these updates should look like in the prompt and
provide examples.

### Real-time cybersecurity safeguards

Requests that involve prohibited or high-risk topics may lead to refusals.

### Fast Mode: Claude Opus 5 / Opus 4.8 only

Fast mode is available on Claude Opus 5 and Opus 4.8. Only surface this if the caller's code actually uses
fast mode (e.g. `model="claude-opus-4-6-fast"`, or `speed="fast"` on an unsupported model); if the word
"fast" does not appear in the code, say nothing about Fast Mode.

When you see `model="claude-opus-4-6-fast"` (or any retired `-fast` model string), **the migration edit is**
to move the fast-mode traffic onto Claude Opus 5, the current fast-capable default (Opus 4.8 also works if
the caller is staying on that tier):

```python
# Request fast mode on Claude Opus 5.
client.beta.messages.create(
    model="claude-opus-5", max_tokens=4096,
    speed="fast", betas=["fast-mode-2026-02-01"],
    messages=[...],
)
```

That is: switch the model to Claude Opus 5 (or Opus 4.8) and request fast mode the supported way, using the
beta `client.beta.messages....` endpoint, the `fast-mode-2026-02-01` beta flag, and `speed="fast"` as a
top-level request parameter (per-language form in SKILL.md ? Fast Mode). Opus 4.7 fast mode has also been
removed, so do not land on Opus 4.7 either. Do **not** leave the code on a retired `-fast` model string --
the failure mode differs by version: `claude-opus-4-6-fast` is retired and the API **silently falls back** to
standard Opus 4.6 (no error -- the caller loses fast-mode speed without noticing); `claude-opus-4-7-fast` and
`speed="fast"` on Opus 4.7 instead return an **API error** (hard failure -- requests break outright rather
than degrading). Either way, migrate to Opus 4.8 fast mode now.

Behavioral shifts (prompt-tunable)

These don't break anything, but prompts tuned for Opus 4.6 may land differently. Opus 4.7 is more steerable
than 4.6, so small prompt nudges usually close the gap.

More literal instruction following. Claude Opus 4.7 interprets prompts more literally and explicitly than
Claude Opus 4.6, particularly at lower effort levels. It will not silently generalize an instruction from one
item to another, and it will not infer requests you didn't make. The upside of this literalism is precision
and less thrash. It generally performs better for API use cases with carefully tuned prompts, structured
extraction, and pipelines where you want predictable behavior. A prompt and harness review may be especially
helpful for migration to Claude Opus 4.7.

Verbosity calibrates to task complexity. Opus 4.7 scales response length to how complex it judges the
task to be, rather than defaulting to a fixed verbosity -- shorter answers on simple lookups, much longer on
open-ended analysis. If the product depends on a particular length or style, tune the prompt explicitly. To
reduce verbosity:

> *"Provide concise, focused responses. Skip non-essential context, and keep examples minimal."*

If you see specific kinds of over-verbosity (e.g. over-explaining), add instructions targeting those.
Positive examples showing the desired level of concision tend to be more effective than negative examples or
instructions telling the model what not to do. Do **not** assume existing "be concise" instructions should be
removed -- test first.
```

Tone and writing style. Opus 4.7 is more direct and opinionated, with less validation-forward phrasing and fewer emoji than Opus 4.6's warmer style. As with any new model, prose style on long-form writing may shift. If the product relies on a specific voice, re-evaluate style prompts against the new baseline. If a warmer or more conversational voice is wanted, specify it:

> *"Use a warm, collaborative tone. Acknowledge the user's framing before answering."*

`effort` matters more than on any prior Opus. Opus 4.7 respects `effort` levels more strictly, especially at the low end. At `low` and `medium` it scopes work to what was asked rather than going above and beyond -- good for latency and cost, but on moderate tasks at `low` there is some risk of under-thinking.

- If shallow reasoning shows up on complex problems, raise `effort` to `high` or `xhigh` rather than prompting around it.
- If `effort` must stay `low` for latency, add targeted guidance: *"This task involves multi-step reasoning. Think carefully through the problem before responding."*
- **At `xhigh` or `max`, set a large `max_tokens`** so the model has room to think and act across tool calls and subagents. Start at 64K and tune from there. (`xhigh` is a new effort level on Opus 4.7, between `high` and `max`.)

Adaptive-thinking triggering is also steerable. If the model thinks more often than wanted -- which can happen with large or complex system prompts -- add: *"Thinking adds latency and should only be used when it will meaningfully improve answer quality -- typically for problems that require multi-step reasoning. When in doubt, respond directly."*

Uses tools less often by default. Opus 4.7 tends to use tools less often than 4.6 and to use reasoning more. This produces better results in most cases, but for products that rely on tools (search/retrieval, function-calling, computer-use steps), it can drop tool-use rate. Two levers:

- **Raise `effort`** -- `high` or `xhigh` show substantially more tool usage in agentic search and coding, and are especially useful for knowledge work.
- **Prompt for it** -- be explicit in tool descriptions or the system prompt about when and how to use the tool, and encourage the model to err on the side of using it more often:

> *"When the answer depends on information not present in the conversation, you MUST call the `search` tool before answering -- do not answer from prior knowledge."*

Fewer subagents by default. Opus 4.7 tends to spawn fewer subagents than 4.6. This is steerable -- give explicit guidance on when delegation is desirable. For a coding agent, for example:

> *"Do NOT spawn a subagent for work you can complete directly in a single response (e.g. refactoring a function you can already see). Spawn multiple subagents in the same turn when fanning out across items or reading multiple files."*

Design and frontend coding. Opus 4.7 has stronger design instincts than 4.6, with a consistent default house style: warm cream/off-white backgrounds (around `#F4F1EA`), serif display type (Georgia, Fraunces, Playfair), italic word-accents, and a terracotta/amber accent. This reads well for editorial, hospitality, and portfolio briefs, but will feel off for dashboards, dev tools, fintech, healthcare, or enterprise apps -- and it appears in slide decks as well as web UIs.

The default is persistent. Generic instructions ("don't use cream," "make it clean and minimal") tend to shift the model to a different fixed palette rather than producing variety. Two approaches work reliably:

1. **Specify a concrete alternative.** The model follows explicit specs precisely -- give exact hex values, typefaces, and layout constraints.
2. **Have the model propose options before building.** This breaks the default and gives the user control:

   > *"Before building, propose 4 distinct visual directions tailored to this brief (each as: bg hex / accent hex / typeface -- one-line rationale). Ask the user to pick one, then implement only that direction."*

If the caller previously relied on `temperature` for design variety, use approach (2) -- it produces meaningfully different directions across runs.

Opus 4.7 also requires less frontend-design prompting than previous models to avoid generic "AI slop" aesthetics. Where earlier models needed a lengthy anti-slop snippet, Opus 4.7 generates distinctive, creative frontends with a much shorter nudge. This snippet works well alongside the variety approaches above:

> *"NEVER use generic AI-generated aesthetics like overused font families (Inter, Roboto, Arial, system fonts), cliched color schemes (particularly purple gradients on white or dark backgrounds), predictable layouts and component patterns, and cookie-cutter design that lacks context-specific character. Use unique fonts, cohesive colors and themes, and animations for effects and micro-interactions."*

```
**Interactive coding products.** Opus 4.7's token usage and behavior can differ between autonomous,
asynchronous coding agents with a single user turn and interactive, synchronous coding agents with multiple
user turns. Specifically, it tends to use more tokens in interactive settings, primarily because it reasons
more after user turns. This can improve long-horizon coherence, instruction following, and coding
capabilities in long interactive coding sessions, but also comes with more token usage. To maximize both
performance and token efficiency in coding products, use `effort: "xhigh"` or `"high"`, add autonomous
features (like an auto mode), and reduce the number of human interactions required from users.

When limiting required user interactions, specify the task, intent, and relevant constraints upfront in the
first human turn. Well-specified, clear, and accurate task descriptions upfront help maximize autonomy and
intelligence while minimizing extra token usage after user turns -- because Opus 4.7 is more autonomous than
prior models, this usage pattern helps to maximize performance. In contrast, ambiguous or underspecified
prompts conveyed progressively over multiple user turns tend to reduce token efficiency and sometimes
performance.

**Code review.** Opus 4.7 is meaningfully better at finding bugs than prior models, with both higher recall
and precision. However, if a code-review harness was tuned for an earlier model, it may initially show
*lower* recall -- this is likely a harness effect, not a capability regression. When a review prompt says
"only report high-severity issues," "be conservative," or "don't nitpick," Opus 4.7 follows that instruction
more faithfully than earlier models did: it investigates just as thoroughly, identifies the bugs, and then
declines to report findings it judges to be below the stated bar. Precision rises, but measured recall can
fall even though underlying bug-finding has improved.

Recommended prompt language:

> *"Report every issue you find, including ones you are uncertain about or consider low-severity. Do not
filter for importance or confidence at this stage -- a separate verification step will do that. Your goal
here is coverage: it is better to surface a finding that later gets filtered out than to silently drop a bug.
For each finding, include your confidence level and an estimated severity so a downstream filter can rank
them."*

This can be used without an actual second step, but moving confidence filtering out of the finding step often
helps. If the harness has a separate verification/dedup/ranking stage, tell the model explicitly that its job
at the finding stage is coverage, not filtering. If single-pass self-filtering is wanted, be concrete about
the bar rather than using qualitative terms like "important" -- e.g. *"report any bugs that could cause
incorrect behavior, a test failure, or a misleading result; only omit nits like pure style or naming
preferences."* Iterate on prompts against a subset of evals to validate recall or F1 gains.

**Computer use.** Computer use works across resolutions up to the new 2576px / 3.75MP maximum. Sending images
at **1080p** provides a good balance of performance and cost. For particularly cost-sensitive workloads,
**720p** or **1366x768** are lower-cost options with strong performance. Test to find the ideal settings for
the use case; experimenting with `effort` can also help tune behavior.

---

## Opus 4.7 Migration Checklist

Every item is tagged: **`[BLOCKS]`** items cause a 400 error, infinite loop, silent truncation, or empty
output if missed -- apply these as code edits, not as suggestions. **`[TUNE]`** items are quality/cost
adjustments -- surface them to the user as recommendations.

`[BLOCKS]` items prefixed with **"If..."** or **"At..."** are conditional. Before working through the list,
**scan the file** for the conditions: does it surface thinking text to a UI/log? Does it set
`output_config.effort` to `"x-high"` or `"max"`? Is it a security workload? Is it a multi-turn agentic loop?
Apply only the items whose condition matches.

- [ ] **[BLOCKS]** Replace `thinking: {type: "enabled", budget_tokens: N}` with `thinking: {type:
"adaptive"}` + `output_config.effort`; delete `budget_tokens` plumbing entirely
- [ ] **[BLOCKS]** Strip `temperature`, `top_p`, `top_k` from request construction
- [ ] **[BLOCKS]** If thinking content is surfaced to users or stored in logs: add `thinking.display:
"summarized"` (otherwise the rendered text is empty)
- [ ] **[BLOCKS]** At `output_config.effort` of `xhigh` or `max`: set `max_tokens` >= 64000 (otherwise output
truncates mid-thought)
- [ ] **[TUNE]** Give `max_tokens` and compaction triggers extra headroom; re-run `count_tokens()` against
`claude-opus-4-7` on representative prompts to re-baseline (no blanket multiplier)
- [ ] **[TUNE]** Re-baseline cost and rate-limit dashboards *before* reacting to measured shifts
- [ ] **[TUNE]** Re-evaluate `effort` per route -- use `xhigh` for coding/agentic and a minimum of `high` for
most intelligence-sensitive work; it matters more on 4.7 than any prior Opus
- [ ] **[TUNE]** Multi-turn agentic loops: adopt the API-native Task Budgets (`output_config.task_budget`,
```

```
beta `task-budgets-2026-03-13`, minimum 20k tokens) -- this is for capping *cumulative* spend across a loop;
per-turn depth is `effort`
- [ ] **[TUNE]** Check for ambiguous or underspecified instructions that relied on 4.6 generalizing intent,
and update them to be clearer or more precise -- 4.7 follows them literally
- [ ] **[TUNE]** Tool-use workloads: add explicit when/how-to-use guidance to tool descriptions (4.7 reaches
for tools less often)
- [ ] **[TUNE]** Verbosity: test existing length instructions before changing them -- 4.7 calibrates length
to task complexity, so tune for the desired output rather than assuming a direction
- [ ] **[TUNE]** Remove forced-progress-update scaffolding (*"after every N tool calls..."*)
- [ ] **[TUNE]** Remove knowledge-work verification scaffolding (*"double-check the slide layout..."*) and
re-baseline
- [ ] **[TUNE]** Add tone instruction if a warmer / more conversational voice is needed; re-evaluate style
prompts on writing-heavy routes
- [ ] **[TUNE]** Subagent tool present: add explicit spawn / don't-spawn guidance
- [ ] **[TUNE]** Frontend/design output: specify a concrete palette/typeface, or have the model propose 4
visual directions before building (the default cream/serif house style is persistent)
- [ ] **[TUNE]** Interactive coding products: use `effort: "xhigh"` or `"high"`, add autonomous features
(e.g. an auto mode) to reduce human interactions, and specify task/intent/constraints upfront in the first
turn
- [ ] **[TUNE]** Code-review harnesses: remove or loosen "only report high-severity" / "be conservative"
filters and have the model report every finding with confidence + severity; move filtering to a downstream
step (4.7 follows severity filters more literally, which can depress measured recall)
- [ ] **[TUNE]** Vision-heavy pipelines (screenshots, charts, document understanding): leave images at native
resolution up to 2576px long edge for the accuracy gain; remove any scale-factor math from coordinate
handling (coords are now 1:1 with pixels). No beta header / opt-in needed -- high-res is automatic on Opus
4.7.
- [ ] **[TUNE]** Computer-use pipelines: send screenshots at 1080p for a good performance/cost balance (720p
or 1366x768 for cost-sensitive workloads); experiment with `effort` to tune behavior
- [ ] **[TUNE]** Cost-sensitive image pipelines: full-res images on 4.7 use up to ~4784 tokens vs ~1,600 on
prior models (~3x). Downsampling client-side before upload avoids the increase, but **do not downsample by
default** -- if you're unsure whether fidelity is needed, ask the user. Re-baseline with `count_tokens()` on
representative images before reacting to cost shifts.

---

## Migrating to Opus 4.8

> **Model ID `claude-opus-4-8` is authoritative as written here.** When the user asks to migrate to Opus 4.8,
write `model="claude-opus-4-8"` exactly. Do **not** WebFetch to verify -- this guide is the source of truth
for migration target IDs. The corresponding entry exists in `shared/models.md`.

Claude Opus 4.8 is our most capable Opus-tier model -- highly autonomous, with state-of-the-art long-horizon
agentic execution, knowledge work, and memory. It is layered on top of the Opus 4.7 migration above. If the
caller is jumping from Opus 4.6 or older, apply the 4.6 and 4.7 sections first, then this one.

**No new breaking changes.** Opus 4.8 keeps the same request surface as Opus 4.7. The same calls that already
work on 4.7 work unchanged on 4.8 -- adaptive thinking only (`thinking: {type: "enabled", budget_tokens: N}`
still 400s; use `{type: "adaptive"}`), sampling parameters (`temperature`, `top_p`, `top_k`) still rejected,
last-assistant-turn prefills still 400, `thinking.display` still defaults to `"omitted"`, and the
`low`/`medium`/`high`/`xhigh`/`max` effort levels, Task Budgets (beta), and high-resolution vision all behave
as on 4.7. A 4.7 -> 4.8 migration is therefore **the model-ID swap plus prompt re-tuning** -- there is no
required code edit beyond the model string.

**TL;DR for someone already on Opus 4.7:** swap the model ID to `claude-opus-4-8`. Nothing else is required
to avoid an error. Then re-tune prompts for the behavioral shifts: 4.8 narrates *more* than 4.7 (add a
silence-default if you want 4.7-like terseness), writes in a warmer, less hedged voice, is more deliberate
and asks more often (add autonomy guidance to claw back ask-rate), and is more conservative about reaching
for search, subagents, file-based memory, and custom tools (add explicit "when to use this" triggering). For
long-horizon agentic work, give the full task specification up front in one well-specified turn and run at
high effort.

### No new API breaking changes (inherited from 4.7)

These all carry over from Opus 4.7 unchanged -- apply them only if the caller is coming from Opus 4.6 or
earlier (see the **Migrating to Opus 4.7** section above for the before/after and the SDK-specific syntax):

- `thinking: {type: "enabled", budget_tokens: N}` -> 400. Use `thinking: {type: "adaptive"}` +
`output_config.effort`.
- `temperature`, `top_p`, `top_k` -> 400. Remove them; steer with prompting.
- Last-assistant-turn prefills -> 400. Use `output_config.format` (structured outputs) or a system-prompt
```

```
instruction.
- `thinking.display` defaults to `"omitted"`; set `"summarized"` if you surface reasoning to users.

If the caller is already on Opus 4.7 and these are clean, there is nothing to change here.

### New API feature: mid-session system prompts

You can deliver trusted instructions partway through a session by placing `{"role": "system", ...}` entries
directly in the `messages` array -- without editing the top-level system prompt and invalidating your prompt
cache. Use it for things the application learns mid-session: the user delivered async context, a mode toggled
(auto-approve enabled), files changed on disk, the remaining token budget dropped.

```python
messages=[
    {"role": "user", "content": [{"type": "tool_result", "tool_use_id": "...", "content": "..."}]},
    {"role": "system", "content": "This project's codebase is Go. Write code in Go."},
]
```

Phrase these as **context, not commands**. State the fact and let Claude act on it; avoid override-style
language ("ignore what the user said", "regardless of the user's request", "disregard the previous
instruction"). Claude is trained to protect users from instructions that appear to work against them, and
that protection applies to the system role too. No beta header is required; available on Claude Opus 4.8. For
cache-placement details and the older-model `<system-reminder>` fallback, see `shared/prompt-caching.md` and
`shared/agent-design.md`.

Capability improvements

Long-horizon agentic execution. Opus 4.8 is state-of-the-art at long, autonomous agentic work -- complex
refactors and overnight coding runs that complete without human correction. To get the most out of it, **give
the full task specification up front in a single well-specified initial turn and run at high effort**
(`effort: "high"` or `"xhigh"`). Its long-horizon coherence comes partly from reasoning more at each step;
combined with a clear up-front goal, that more-intelligent planning often produces more efficient *and* more
accurate output than prior frontier models. The "clear goal up front" principle maps to two product surfaces:
in Claude Code, `/goal` sets direction for the run; with **Managed Agents (CMA)**, state what "done" looks
like via an **Outcome** (`user.define_outcome` with a gradeable rubric -- the harness runs an iterate ->
grade -> revise loop), see `shared/managed-agents-outcomes.md`.

Effort is a dimension to test, not a fixed setting. On prior models many reached for `xhigh` reflexively
to maximize intelligence. Opus 4.8 has a higher intelligence ceiling, so **start at `high` as the default and
iterate** rather than defaulting to `xhigh`. Sweep `medium`, `high`, and `xhigh` on your own eval set and
weigh the intelligence <-> latency <-> cost tradeoff per route -- the relationship isn't monotonic: higher
effort up front often *reduces* turn count and total cost on agentic work, while for some tasks `medium`
delivers equally good results in less time. Reserve `max` for extremely hard, latency-insensitive cases. The
per-level effort table in the **Migrating to Opus 4.7** section above applies unchanged on 4.8.

Writing voice and clarity. Testers consistently describe 4.8's prose as clearer, warmer, and less hedged
than prior models, with fewer measurable AI vocal tics -- especially at higher effort, where it approaches
expert-level prose and structure. This is roughly the **opposite** direction from the 4.7 shift (4.7 was more
clipped, direct, and less validation-forward). If you added style prompts to counter 4.7's terseness or to
inject warmth, re-evaluate them against the new baseline before keeping them -- they may now overcorrect. 4.8
is also a stronger thought partner: more thoughtful, more willing to push back, and more likely to infer the
right answer from context.

Code review and debugging. Stronger real-bug finding and clearer explanations than 4.7 -- one-shot fixes
where 4.7 needed more, and correctly identifying intermittent flakes rather than declaring "fixed" after one
clean run. The 4.7 caveat still applies: if a review harness says "only report high-severity issues" or "be
conservative", 4.8 follows it literally and measured recall can drop even though underlying bug-finding
improved. Tell the model to report everything and filter downstream (or review a second time) -- see the
Code review guidance in the 4.7 section for the recommended prompt.

Behavioral shifts (prompt-tunable)

None of these break code, but prompts tuned for Opus 4.7 may land differently. 4.8 follows instructions well,
so small, explicit nudges close the gap.

Tool triggering is surface-dependent (search & knowledge). 4.8's tool-triggering is more
surface-dependent than in prior models: with a system prompt present it is high-precision / low-recall -- web
search triggers slightly more often but runs fewer rounds per trigger, while knowledge-retrieval tools
(Drive, project knowledge, connected files) trigger *less* often. It searches when it's confident search is
```

needed and otherwise answers from context, which can lower research depth on tasks that need it. Recover should-search rate with an explicit search-first instruction:

> ```
> <search_first>
> For questions where current information would change the answer (recent events, current roles or prices, version-specific behavior, or anything the user flags as time-sensitive) search before answering rather than answering from memory. For open-ended research requests, begin searching immediately; do not ask a scoping question first unless the request is genuinely ambiguous about what to research.
> </search_first>
> ```

Under-utilization of subagents, memory, and custom tools. Separately from search, 4.8 is conservative about reaching for capabilities that need an explicit "decide to use this" step -- file-based memory, subagent delegation, custom tools. It won't reach for complex or expensive capabilities unless reasonably sure they're needed. This is steerable since 4.8 follows instructions well -- say *when* each capability applies, not just that it exists:

> *"Before any task longer than a few turns, check your memory file for relevant prior context and write new findings to it as you go. When a task fans out across independent items (many files to read, many tests to run, many candidates to check), delegate to subagents rather than iterating serially."*

The same lever works at the **tool-description** level, not just the system prompt: prescriptive descriptions that state *when* to call a tool (e.g. "Call this when the user asks about current prices or recent events") give meaningful lift on 4.8 over descriptions that only state what the tool does. Make the trigger condition part of each capability's own `description`.

More user-facing narration. 4.8 narrates more than 4.7 -- more text between tool calls in long tool-calling sessions, and longer, more detailed end-of-task wrap-ups by default. If you previously added scaffolding to force interim status ("after every 3 tool calls, summarize progress"), **remove it** -- 4.8 does this on its own. If the narration is too verbose for a coding agent, an explicit silence-default makes it behave like 4.7 with no loss of quality:

> *"Default to silence between tool calls. Only write text when you find something, change direction, or hit a blocker -- one sentence each. Do not narrate routine actions ('Now I'll...', 'Let me check...', 'Looking at...'). When done: one or two sentences on the outcome. Do not recap every file or test -- the user has been following along."*

For knowledge-work deliverables (reports, analysis readouts), verbosity responds very well to instructions in user preferences or the user turn -- expose a verbosity preference rather than hard-coding a length.

More deliberate -- asks more often. 4.8 is more deliberate than prior Opus models. On minor decisions it would previously just make (a variable name, a default value, which of two equivalent approaches), it tends to pause and ask, and it often closes a completed task with "Want me to also...?" rather than doing the obvious next step or stopping cleanly. This is preferred for high-stakes or unfamiliar codebases, but bugs users when uncalibrated. Grant autonomy on the small stuff while keeping caution where it matters (in Claude Code testing this cut ask-rate by ~12 percentage points with no increase in over-reach):

> *"For minor choices (naming, formatting, default values, which approach among equivalents), pick a reasonable option and note it rather than asking. For scope changes or destructive actions, still ask first."*

Verbose reasoning when thinking is disabled. With `thinking: {type: "disabled"}`, 4.8 occasionally writes longer explanations of its reasoning into the visible response, which reads as verbose when the user wants a fast, quick answer. The simplest fix is to leave adaptive thinking on -- set `thinking: {type: "adaptive"}` (the recommended setting; it adjusts how much to think per task). Note adaptive is **not** on when the field is omitted -- like Opus 4.7, a request with no `thinking` field runs without thinking, so set it explicitly. If you need thinking off for latency or cost, scope it in the system prompt:

> *"Respond only with your final answer. Do not include exploratory reasoning, intermediate drafts, diffs you considered but rejected, or meta-commentary about your process."*

Opus 4.8 Migration Checklist

Every item is tagged: **`[BLOCKS]`** items cause a 400 error if missed; **`[TUNE]`** items are quality/cost adjustments -- surface them to the user as recommendations.

For a caller **already on Opus 4.7**, only the first item is required; everything else is `[TUNE]`. The conditional `[BLOCKS]` item applies only when coming from Opus 4.6 or earlier.

- [ ] **[BLOCKS]** Update the `model=` string to `claude-opus-4-8`

```
- [ ] **[BLOCKS]** *(only if coming from Opus 4.6 or earlier)* Apply the **Migrating to Opus 4.7** breaking changes first -- `budget_tokens` -> adaptive thinking, strip `temperature`/`top_p`/`top_k`, remove last-assistant-turn prefills. These already 400 on 4.7 and continue to 400 on 4.8.
- [ ] **[TUNE]** Long-horizon / agentic work: put the full task spec in one well-specified first turn and run at `high` or `xhigh` effort (Claude Code: `/goal`; Managed Agents: an Outcome with a gradeable rubric)
- [ ] **[TUNE]** Effort: sweep `medium` / `high` / `xhigh` on your eval set and pick per route by the intelligence <-> latency <-> cost tradeoff (default `high`, `xhigh` for coding/agentic)
- [ ] **[TUNE]** Research depth & tool use: add a search-first instruction; add explicit triggering guidance for subagents, file-based memory, and custom tools (4.8 under-reaches for these by default) -- in the system prompt *and* in each tool's own `description` (prescriptive "call this when..." descriptions give measurable lift)
- [ ] **[TUNE]** Narration: remove forced-progress scaffolding (*"after every N tool calls..."*); add a silence-default if a coding agent is too chatty
- [ ] **[TUNE]** Autonomy: add small-decisions-don't-ask guidance to cut ask-rate, while keeping caution on scope changes / destructive actions
- [ ] **[TUNE]** Writing voice: re-evaluate style prompts added to counter 4.7's directness -- 4.8 is warmer and less hedged by default; re-baseline before keeping them
- [ ] **[TUNE]** Code-review harnesses: keep the report-everything-filter-downstream pattern (4.8 follows "only high-severity" / "be conservative" filters literally, which can depress measured recall)
- [ ] **[TUNE]** Thinking-disabled paths: add a final-answer-only instruction if reasoning leaks into the visible response
- [ ] **[TUNE]** Consider mid-session system messages (`role:"system"` in `messages`; no beta header) for context the app learns mid-session, instead of rebuilding the top-level system prompt and invalidating the cache

---

## Migrating to Claude Opus 5

> **Model ID `claude-opus-5` is authoritative as written here.** When the user asks to migrate to Claude Opus 5, write `model="claude-opus-5"` exactly. Do **not** WebFetch to verify -- this guide is the source of truth for migration target IDs. The corresponding entry exists in `shared/models.md`.

Claude Opus 5 is the successor to Claude Opus 4.8 in the Opus line, and is strongest on long-horizon agentic work and coding. It is layered on top of the Opus 4.8 migration above; if the caller is coming from Opus 4.7 or older, apply those sections first. Like Claude Fable 5, it ships with **elevated cybersecurity safeguards, and its safety classifiers can decline a request**: you get a normal HTTP 200 with `stop_reason: "refusal"` and a `stop_details` category, not an error. Benign security and life-sciences work occasionally trips them, so **check `stop_reason` before reading `response.content`** -- code that indexes `content[0]` unconditionally breaks on a refusal. Cyber-category refusals route to Opus 4.8 as the recommended fallback, so a fallback strategy genuinely recovers the request rather than just relabelling the failure. The full refusal semantics (pre-output vs mid-stream billing, retry strategies, fallback credit) are in the Claude Fable 5 section below and apply here unchanged.

Existing prompts and evals should carry over with strong out-of-the-box performance. **It is a drop-in upgrade at Opus 4.8's pricing** -- $5 per million input tokens, $25 per million output -- with the same feature set: 1M context (default, no beta header), 128K max output, adaptive thinking, prompt caching, batch processing, the Files API, PDF support, vision, and the full server-side and client-side tool set. `claude-opus-5` is a fixed ID with no date suffix, same scheme as `claude-opus-4-8`.

The migration is **the model-ID swap plus prompt re-tuning**, with two breaking changes covered below.

**Availability at launch:** Claude API (`claude-opus-5`), Amazon Bedrock (`anthropic.claude-opus-5`), Google Cloud (`claude-opus-5`), and Microsoft Foundry. Opus 4.8 stays available on all four.

**Rate limits are a separate bucket.** Opus 4.8/4.7/4.6/4.5 share one combined Opus limit; Claude Opus 5 does **not** draw from it. Shifting traffic over neither frees headroom on the old bucket nor inherits it -- check your tier's Claude Opus 5 limits before moving volume.

**TL;DR for someone already on Claude Opus 4.8:** swap the model ID. Then re-tune: Claude Opus 5 writes longer user-facing responses and longer files on disk (add explicit conciseness and deliverable-length instructions -- `effort` does not reliably shorten visible output), verifies its own work without being told (**delete** your verification instructions and harness verification steps), and can expand task scope (add a scope-discipline instruction). Run a fresh effort sweep -- `low` and `medium` are unusually strong here and are the primary cost/latency lever.

### Breaking change 1: thinking is on by default

A request that omits the `thinking` parameter **thinks** on Claude Opus 5, unlike Claude Opus 4.8 and Opus 4.7 where omitting it meant no thinking. `thinking: {type: "adaptive"}` remains valid and is equivalent to
```

```
the default -- the wire value didn't change, the default did.

This is a silent cost and truncation change, not just a behavior one: **`max_tokens` is a hard cap on
thinking *plus* response text.** A workload that ran without thinking on Opus 4.8 and sized `max_tokens`
tightly around its answer can now truncate mid-response. Revisit `max_tokens` on every route that never set
`thinking`. To keep the old behavior, pass `thinking: {type: "disabled"}` -- subject to the effort cap below.

Raw thinking tokens are **never returned** on Claude Opus 5; `display` defaults to `"omitted"`, and `display:
"summarized"` gets you a summary. This also means a fallback model cannot read Claude Opus 5's thinking.

### Breaking change 2: disabling thinking is capped at `high` effort

Disabling thinking is available only at effort **`high` or lower**; `thinking: {type: "disabled"}` combined
with `xhigh` or `max` returns a 400. Opus 4.8 accepts that combination, so audit any route that disables
thinking before migrating.

**The check is per request.** Effort and thinking are validated independently on every call, so a later
request that raises effort to `xhigh` while thinking is still disabled is rejected even though earlier
requests in the same conversation succeeded.

```python
# 400 on Claude Opus 5 -- disabled thinking above `high`
client.messages.create(
    model="claude-opus-5",
    max_tokens=4096,
    thinking={"type": "disabled"},
    output_config={"effort": "xhigh"},
    messages=[...],
)
```

Migrating: either enable thinking at `xhigh`/`max`, or lower effort to `high` or below. Given how well
Claude Opus 5 performs at `low` and `medium`, a latency-sensitive route that previously ran `xhigh` +
disabled thinking is usually better served by `medium` with thinking on than by keeping the disabled path.

Everything else from the Opus 4.7/4.8 request surface is unchanged: `budget_tokens` still 400s (use
`output_config.effort`), sampling parameters (`temperature`, `top_p`, `top_k`) are still rejected,
last-assistant-turn prefills still 400, and `thinking.display` still defaults to `"omitted"`.

Two failure modes when thinking is disabled

Are you affected? Only if you explicitly set `thinking: {type: "disabled"}`. Thinking is on by default on
Claude Opus 5 (see Breaking change 1 above), so an unmodified request never hits either of these -- but code
carrying a disabled-thinking setting forward from Opus 4.8, where it was the default behaviour, does.

Both are specific to `thinking: {type: "disabled"}` on Claude Opus 5, and for both the **primary
recommendation is the same: turn thinking back on and use a lower `effort` to control cost and verbosity
instead.** Disabling thinking is the more expensive lever in every sense -- it is what triggers these, and
`low`/`medium` effort already gets you most of the token and latency saving (see ? Effort below).

1. Tool calls can arrive as plain text. The model occasionally writes a tool call into its user-facing
text rather than emitting a structured `tool_use` block. **The turn completes normally and the call never
runs** -- there is no error and no `tool_use` block to catch, so a harness sees a successful turn that
silently did nothing. Worse in an agentic loop: the bogus text stays in conversation history and skews later
turns. Most common on tool-heavy workloads such as search.

If you cannot enable thinking, give the model explicit permission to talk first -- the failure appears to
come from suppressing the preamble it wants to write:

> *"You may say a brief sentence before using a tool."*

2. `<thinking>` tags can leak into the visible response. The model may emit `<thinking>` or other
internal XML in its user-facing output.

If you cannot enable thinking, there are two counterintuitive rules here:

- **Delete any instruction telling the model not to think or not to reason.** That kind of rule *increases*
tag leakage rather than suppressing it.
- **Write the instruction generically, and do not name thinking tags.** Calling them out by name is
measurably less effective than the general form:
```

```
> *"Do not include internal or system XML tags in your response."*

### New API features

Two additions, each behind its own beta header. Both are optional -- a migrated request works without them.

**1. `fallbacks: "default"` -- recommended for every caller.** Claude Opus 5's safety classifiers can decline
a request; the `fallbacks` parameter re-runs a declined request on another model server-side instead of
returning the refusal to you. Previously you named the substitute yourself (`"fallbacks": [{"model":
"claude-opus-4-8"}]`). The new `"default"` mode picks Anthropic's recommended fallback automatically, routed
**by refusal category** -- cyber-category refusals go to Claude Opus 4.8.

```http
POST /v1/messages
anthropic-beta: server-side-fallback-2026-07-01

{"model": "claude-opus-5", "fallbacks": "default", "max_tokens": 1024,
 "messages": [{"role": "user", "content": "Say OK."}]}
```

Prefer `"default"` over pinning a model. Different fallback models carry different classifiers, so the
right substitute depends on *why* the request was declined -- and `"default"` removes the migration you would
otherwise owe when a pinned fallback model is deprecated. Note the header is
`server-side-fallback-2026-07-01`, distinct from the `-2026-06-01` header that gates the array form; the
array form's semantics (content blocks, `usage.iterations`, sticky routing) are unchanged and documented in
the Claude Fable 5 refusal section below.

2. Mid-conversation tool changes (beta `mid-conversation-tool-changes-2026-07-01`). Change a
conversation's tool set between turns without invalidating the prompt cache. Previously `tools` was fixed for
the conversation's lifetime and any edit re-billed the whole prefix. Append a `{"role": "system", "content":
[...]}` message carrying a `tool_addition` or `tool_removal` block:

```python
messages = [
    {"role": "user", "content": "What tools do you have for weather in Paris?"},
    {"role": "system", "content": [
        {"type": "tool_addition", "tool": {"type": "tool_reference", "name": "get_forecast"}},
    ]},
]
```

The added tool must already be declared in `tools[]` with `"defer_loading": True` -- declared up front, but
not loaded into context until a `tool_addition` surfaces it. A `tool_removal` block must sit either
immediately before an assistant message or at the end of `messages`. To *change* a tool's definition, remove
the old one on one request, then send the updated entry in `tools[]` on the next. See
`shared/tool-use-concepts.md` ? Mid-conversation tool changes.

> ?? Earlier previews of this feature used a different beta header and different block shapes. Both are
deprecated -- if the code you're migrating carries anything other than
`mid-conversation-tool-changes-2026-07-01` with `tool_addition` / `tool_removal` / `tool_reference`, update
the header and the shapes together.

> **SDK typings lag these blocks.** Pass them as plain dicts in Python (the SDK forwards unknown keys
unchanged) or add a `@ts-expect-error` in TypeScript until the types catch up. `extra_body` / `extra_headers`
work on `.stream()` exactly as on `.create()`.

Capability improvements

Agentic coding. Claude Opus 5 is a workhorse for agentic coding and is strongest on *difficult* tasks --
multi-file features, larger refactors, end-to-end feature work. It completes tasks rather than leaving stubs
or placeholders. The gap over prior models is smaller on easy single-turn edits, so evaluate it on the hard
end of your workload. To get the most out of it, give the complete task specification up front and let it
run; longer autonomous sessions with more parallel agents show the strongest results, short interactive edits
the least.

Code review and bug-finding. High precision *and* high recall -- a high rate of real bugs per pass, with
the extra findings mostly real rather than false positives. It stays accurate at lower effort, which makes a
cheap fast pass at review time plus a thorough pass later a practical pattern.
```

```
**Effort: the full ladder, and where to start.** Claude Opus 5 supports all five levels -- `low`, `medium`,
`high`, `xhigh`, `max` -- with no beta header. The API default is `high`.

The published starting points and the model's measured behavior pull in slightly different directions, and
both are worth knowing:

- **Start at `xhigh` for coding and agentic work, `high` for other intelligence-sensitive workloads.** That's
the documented recommendation, and `max` is the explicit top tier for the deepest reasoning -- worth testing
where capability matters more than spend, though it can show diminishing returns and overthink simpler tasks.
- **Then sweep downward, because `low` and `medium` punch well above their weight on this model** -- strong
quality at a fraction of the tokens and latency on many workloads. Step down only where your evals show
quality holds, but do run the sweep: effort defaults carried over from a prior model are usually not the
right setting here.

At `xhigh` or `max`, **set a large `max_tokens`** so the model has room to think and act across tool calls
and subagents. Start at 64K and tune.

**Lower prompt-cache minimum.** The minimum cacheable prompt is **512 tokens** on Claude Opus 5, down from
1024 on Opus 4.8. Prompts previously too short to cache now create entries with no code change -- worth
re-checking any prompt you'd written off as uncacheable. See `shared/prompt-caching.md`.

**Fast mode.** `speed: "fast"` (beta header `fast-mode-2026-02-01`) is supported on Claude Opus 5, priced at
$10 / $50 per MTok. It is a research preview on the **Claude API only** -- including Managed Agents -- and is
**not** available on Amazon Bedrock, Google Cloud, or Microsoft Foundry. Fast mode draws on dedicated rate
limits separate from the standard Opus pools.

**Vision -- give it tools, not more thinking.** Stronger on chart, document, and diagram understanding, and
on UI and frontend visual replication. The highest-leverage change is **giving it tools to iteratively
analyze, crop, and visually verify its own work**: on this model tool use is a markedly more cost-effective
lever than raising thinking alone. Claude Opus 5 sits in the high-resolution tier alongside Opus 4.8 -- 2576
px on the long edge, up to 4784 visual tokens per image -- so coordinates map 1:1 to pixels and no
scale-factor math is needed. Any prompt-side workaround you added for a prior model's vision limitations
should be re-validated; several are now counterproductive.

**Long context.** 1M-token context window as both the default *and* the maximum. Instruction following, tool
calling, and reasoning stay strong across the full window.

**Office and document tasks.** Generates and edits complex multi-sheet Excel files with non-trivial formulas,
and visually strong PowerPoint decks that follow slide-design best practices. It can be prompted to adhere to
a specific style or template when one is required.

**Multi-agent coordination.** Coordinates teams of subagents well -- few cases of agents overwriting each
other's work, and effective use of writer-verifier patterns. Workloads that benefit from multi-agent patterns
are good fits. **Cost-sensitive workloads should cap multi-agent usage** -- see the delegation section below,
because this model reaches for subagents more readily than its predecessors.

### Behavioral shifts (prompt-tunable)

**Longer user-facing responses.** Default response text is longer than on prior models. **`effort` is not the
lever here** -- changing it may move thinking volume without reliably changing visible output length.
Prompting is: in testing, a short conciseness instruction cut user-facing response length by ~20%.

> *"Keep responses focused, brief, and concise to avoid overwhelming the person. Disclaimers and caveats are
brief, with most of the response on the main answer; when asked to explain something, give a high-level
summary unless an in-depth one is specifically requested."*

For a long system prompt, pair that with a one-line reminder near the end:

> ```
> <tone_preference>
> Keep outputs reasonably concise.
> </tone_preference>
> ```

More narration in agentic sessions (the lever runs both ways -- the same explicit-description technique
tunes narration *up* or restyles it, if your product wants more). Claude Opus 5 narrates what it is about to
do, and its per-message output in agentic sessions is longer than prior models'. It responds well to explicit
guidance on *how* to communicate during a task rather than just *how much*. For coding agents, this block
calibrates it:
```

> ```
> # Communicating with the user
> Your text output is what the user reads between tool calls; they usually can't see your thinking or the raw tool results. Write it for a teammate who stepped away and is catching up, not for a log file: they don't know the codenames or shorthand you created along the way, and they didn't watch your process unfold. Before your first tool call, say in a sentence what you're about to do; while working, give brief updates when you find something load-bearing or change direction.
>
> Lead with the outcome. Your first sentence after finishing should answer "what happened" or "what did you find" -- the thing the user would ask for if they said "just give me the TLDR." Supporting detail and reasoning should come after, for readers who want them.
>
> Being readable and being concise are different things, and readable matters more. If the user has to reread your summary or ask you to explain, any time saved by brevity is gone. The way to keep output short is to be selective about what you include (drop details that don't change what the reader would do next), not to compress the writing into fragments, abbreviations, arrow chains like `A -> B -> fails`, or jargon. What you do include, write in complete sentences with the technical terms spelled out. Don't make the reader cross-reference labels or numbering you invented earlier; say what you mean in place.
>
> Match the response to the question: a simple question should be answered with a direct answer in prose, not headers and sections. Use tables only for short enumerable facts, with explanations in the surrounding prose rather than the cells. Calibrate to the user -- a bit tighter for an expert, more explanatory for someone newer.
>
> Write code that reads like the surrounding code: match its comment density, naming, and idiom.
>
> Only write a code comment to state a constraint the code itself can't show -- never to say where it came from, what the next line does, or why your change is correct; that's you talking to the reviewer, not the next reader, and it's noise the moment the PR merges.
> ```

Longer written deliverables. Separate from conversational verbosity: files Claude Opus 5 writes to disk -- reports, Markdown documents, summaries -- are often longer than on prior models. If your product ships Claude-authored documents, calibrate length explicitly:

> *"Match the length of written deliverables (especially Markdown files) to what the task needs: cover the substance, but do not pad documents with filler sections, redundant summaries, or boilerplate."*

Self-check instructions are the same trap. Beyond harness scaffolding, per-prompt re-check phrasing -- *"double-check your answer"*, *"re-verify before responding"* -- triggers the same extra work. Note this **inverts a standard prompting best practice**: "ask Claude to self-check" is generally sound advice and is wrong here, so a prompt library that applies it uniformly needs a carve-out for this model rather than a global rule.

Over-verification -- delete your verification scaffolding. Claude Opus 5 verifies its own work without being asked. Instructions that *tell* it to verify ("include a final verification step for virtually any non-trivial task", "use a subagent to verify") now cause over-verification. **Removing them reduces over-verification with no capability regression** -- this is a delete, not a rewrite. The same applies to harness-level scaffolding: separate verification steps carried over from prior models are likely redundant now.

Task scope expansion. It can add steps the user didn't request, or apply its own judgment about what the task should be without making that clear. In testing, this instruction reduced scope changes to nearly zero without producing excessive clarifying questions:

> *"Deliver what the user asked for, at the scope they intended. Interpret ambiguity the way a careful colleague would: make routine judgment calls yourself, and check in only when different readings would lead to materially different work. If you conclude the ask is mistaken or a better approach exists, say so in a sentence and keep going with the task as asked -- don't quietly narrow, widen, or transform it. Finish the whole task, not just the easy part of it - only report completion when it's fully done. If you genuinely can't complete something, do the rest and state plainly what's missing and why. Stop short of actions or changes that are clearly beyond what the user's ask implies."*

The revised wording adds a **finish-the-whole-task** clause -- report completion only when the work is actually done, and if something genuinely can't be finished, do the rest and say plainly what is missing. That covers premature "done" claims, which scope-discipline wording alone did not.

Delegates to subagents more readily -- the opposite of Opus 4.8. This is a direction change worth flagging: Opus 4.8 *under*-reached for subagents and needed prompting to delegate. Claude Opus 5 reaches for

them freely, which multiplies cost and latency -- each subagent re-establishes context, re-explores, reports back, and then the coordinator re-reads the report. If your harness supports subagents, **any "delegate more" guidance you added for Opus 4.8 should come out**, and you likely want an explicit cap. A deterministic ceiling on spawn count is the reliable lever; this block reduces delegation and token spend:

> ```
> ## Delegating to subagents
> Subagents multiply cost and time: each one re-establishes context, re-explores, and reports back, and you then re-read its report. Delegate rarely and only when the payoff clearly exceeds that overhead.
>
> Do use subagents for:
> - Large tasks that are genuinely independent and parallelizable. For example, wide multi-file investigations.
>
> Do NOT use subagents for:
> - Work you could finish yourself in a handful of tool calls. For example: a few file reads, a handful of edits, a simple search task, relatively simple verification.
> - Review, verification, or to double check your work. Verification belongs in your main agent loop.
>
> Use of parallel or multiple subagents:
> - Do not use multiple subagents on a single small task. Parallel subagents are for genuinely independent, sizeable tracks (unrelated modules, a wide multi-file investigation), not for splitting one modest job into pieces.
> - If the task can be completed with one subagent, choose one subagent over multiple subagents. Keep spawn counts low.
> - Never use more than 20 parallel agents unless the user explicitly requests it.
>
> When delegating to subagents:
> - Brief the subagent precisely the first time. Avoid launching, waiting, and re-briefing.
> - If you delegate, commit to the delegation. Never redo the subagent's work and do not re-derive its findings once it reports back.
> - If you launch multiple agents for independent work, send them in a single message with multiple tool uses so they run concurrently.
> ```

Note the interaction with over-verification below: "do not use subagents to verify" and "delete your verification scaffolding" are the same underlying fix seen from two angles.

Narrates self-corrections more than prior models. It flags and explains its own earlier mistakes at length, which reads as thrash in a user-facing product. Scope corrections to the ones that actually change the user's outcome:

> ```
> # Corrections
> Avoid unnecessary or excessive self-correction. Only correct an earlier statement in your user-facing text when the error would change the user's code, conclusions, or decisions. State corrections plainly and concisely, and continue the task; combine multiple corrections rather than enumerating them all. For slips that change nothing for the user, simply make the correction and move on - no need to note it explicitly. Don't add apologies or preambles, don't be overly self-critical, and don't ruminate or give a detailed account of the mistake or tally past errors. Sometimes, other agents will report incorrect or misleading results - don't always take them at face value immediately. If other agents correct your statements and they are right, then simply update your approach without narrating too much about the correction to the user. This instruction does not apply to thinking blocks.
>
> A follow-up question about your earlier work is not, by itself, a signal that you got something wrong -- answer what was asked. A statement that was accurate needs no correction: don't re-audit how you phrased it, how you verified it, or limits you already stated. When the user does point to a real error, correct it plainly as above.
> ```

The second paragraph matters as much as the first: a plain follow-up question can otherwise trigger a re-audit of work that was correct.

Severity filters still depress measured recall. Unchanged from 4.7/4.8: if a review harness says "only report high-severity issues" or "be conservative", Claude Opus 5 follows it literally. Ask it to report everything with confidence and severity, and filter in a separate pass -- see the **Code review** guidance in the Opus 4.7 section for the recommended prompt.

Claude Opus 5 Migration Checklist

```
**`[BLOCKS]`** items cause a 400 error if missed; **`[TUNE]`** items are quality/cost adjustments -- surface
them to the user as recommendations.

- [ ] **[BLOCKS]** Update the `model=` string to `claude-opus-5`
- [ ] **[BLOCKS]** Any route combining `thinking: {type: "disabled"}` with `effort` of `xhigh` or `max`:
enable thinking, or lower effort to `high` or below. Validated per request, so audit every call site, not
just the first
- [ ] **[BLOCKS]** Every route that never set `thinking`: it now thinks, and `max_tokens` caps thinking +
response text together. Raise `max_tokens` or pass `thinking: {type: "disabled"}` at effort `high` or below
-- otherwise responses truncate mid-answer
- [ ] **[BLOCKS]** *(only if coming from Opus 4.7 or earlier)* Apply the **Migrating to Opus 4.7** breaking
changes first -- `budget_tokens` -> adaptive thinking, strip `temperature`/`top_p`/`top_k`, remove
last-assistant-turn prefills
- [ ] **[TUNE]** Effort: start `xhigh` for coding/agentic and `high` elsewhere, then sweep down --
`low`/`medium` are unusually strong here, and prior-model defaults rarely transfer. At `xhigh`/`max`, set
`max_tokens` to at least 64K
- [ ] **[TUNE]** Re-check prompts you'd written off as uncacheable -- the minimum drops to 512 tokens (from
1024 on Opus 4.8)
- [ ] **[TUNE]** Rate limits: Claude Opus 5 is a separate bucket from the combined Opus 4.x pool -- confirm
your tier's limits before shifting volume
- [ ] **[TUNE]** Fast mode (`speed: "fast"`, `fast-mode-2026-02-01`, $10/$50) is Claude-API-only -- drop it
on Bedrock, Google Cloud, and Foundry routes
- [ ] **[TUNE]** Verbosity: add a conciseness instruction (and a `<tone_preference>` tag for long system
prompts). Do **not** try to shorten output by lowering `effort` -- it doesn't reliably work
- [ ] **[TUNE]** Agentic sessions: add a "Communicating with the user" block to calibrate inter-tool-call
narration
- [ ] **[TUNE]** Claude-authored files: add a deliverable-length instruction
- [ ] **[TUNE]** **Delete** verification instructions from prompts and verification steps from the harness --
including per-prompt *"double-check your answer"* phrasing, which inverts the usual self-check best practice
on this model
- [ ] **[TUNE]** Add the scope-discipline instruction if the model expands task scope
- [ ] **[TUNE]** Vision pipelines: re-validate prompt-side workarounds written for a prior model's vision
limitations
- [ ] **[TUNE]** Consider mid-conversation tool changes (`mid-conversation-tool-changes-2026-07-01`) --
changes the tool set between turns without invalidating the prompt cache. Note per-turn `effort` /
`task_budget` are **not** in this launch; both stay request-level
- [ ] **[TUNE]** Subagent-capable harnesses: this model delegates *more* readily than Opus 4.8 -- remove any
"delegate more" guidance you added for 4.8 and add an explicit cap
- [ ] **[TUNE]** User-facing products: add the corrections instruction if self-correction narration reads as
thrash
- [ ] **[TUNE]** Any route running `thinking: {type: "disabled"}`: prefer turning thinking on at
`low`/`medium` effort. Disabled thinking can emit tool calls as plain text (the call silently never runs) and
leak `<thinking>` tags into output. If you must stay thinking-off, add *"You may say a brief sentence before
using a tool"*, delete any don't-think/don't-reason rule, and use a generic *"no internal or system XML
tags"* instruction
- [ ] **[TUNE]** Vision pipelines: give it crop/analyze/verify tools -- cheaper and more effective than
raising thinking
- [ ] **[TUNE]** Handle `stop_reason: "refusal"` before reading `content`, and opt into `fallbacks:
"default"` (`server-side-fallback-2026-07-01`) rather than pinning a model -- cyber-category refusals route
to Claude Opus 4.8
- [ ] **[TUNE]** Long-horizon / agentic work: give the complete task spec up front in one turn rather than
building it up across interactive turns

---

## Migrating to Claude Sonnet 5

> **Model ID `claude-sonnet-5` is authoritative as written here.** When the user asks to migrate to Claude
Sonnet 5, write `model="claude-sonnet-5"` exactly. Do **not** WebFetch to verify -- this guide is the source
of truth for migration target IDs. The corresponding entry exists in `shared/models.md`.

Claude Sonnet 5 substantially improves on Sonnet 4.6 for coding and agentic work, reaching what was
previously Opus-tier quality on many tasks. Its API surface aligns with Opus 4.7/4.8: manual extended
thinking is removed (adaptive or disabled only, adaptive is the default), and non-default sampling parameters
are rejected. This section is layered on top of the Sonnet 4.6 migration above -- if the caller is jumping
from Sonnet 4.5 or older, apply the 4.6 changes first, then this one.

**TL;DR for someone already on Sonnet 4.6:** swap the model ID to `claude-sonnet-5`. Replace any remaining
`thinking: {type: "enabled", budget_tokens: N}` with `thinking: {type: "adaptive"}` (the transitional escape
hatch is gone -- it now 400s), and note that omitting `thinking` now runs adaptive (4.6 ran thinking-off).
```

Strip non-default `temperature`/`top_p`/`top_k`. Re-run `count_tokens()` against `claude-sonnet-5` -- the new tokenizer produces ~30% more tokens for the same text, so token-budgeted limits and cost baselines shift even though per-token pricing is unchanged. `effort` defaults to `high`, the same as Sonnet 4.6 -- raise to `xhigh` for the hardest coding and agentic tasks (Claude Sonnet 5 supports the full `low`/`medium`/`high`/`xhigh`/`max` range), and give `max_tokens` headroom at `xhigh`/`max` (the new tokenizer means a Sonnet-4.6-tuned `max_tokens` may truncate equivalent output). Then re-tune prompts: Claude Sonnet 5 interprets instructions more literally than 4.6 -- holdover style/tone directives now apply at face value; it is more agentic by default and reaches for tools and self-verification loops more readily (with thinking disabled it is less tool-eager -- add an explicit nudge); it gives better in-progress updates by default (drop forced "summarize every N tool calls" scaffolding); and code-review harnesses with conservative-reporting instructions may see lower recall (tell it to report everything and filter downstream).

Breaking changes (will 400 on Claude Sonnet 5)

These bring the Sonnet line onto the same request surface as Opus 4.7/4.8. See the **Per-SDK Syntax Reference** above for the language-specific spelling of each.

1. Extended thinking removed -- adaptive only. `thinking: {type: "enabled", budget_tokens: N}` returns a 400. The transitional escape hatch that still worked on Sonnet 4.6 is gone. Use adaptive thinking with an effort hint:

```python
# Before -- deprecated on Sonnet 4.6, now errors on Claude Sonnet 5
thinking={"type": "enabled", "budget_tokens": 10000}

# After
thinking={"type": "adaptive"},
output_config={"effort": "high"},  # or "xhigh" for the hardest coding/agentic tasks
```

To turn thinking off entirely, set `thinking: {type: "disabled"}` -- but see *Adaptive vs. disabled* below before doing so.

2. Sampling parameters rejected. Setting `temperature`, `top_p`, or `top_k` to a non-default value returns a 400; omitting the parameter, or passing its default, is still accepted. The safest migration is to omit them entirely and steer with prompting. If the caller was relying on `temperature=0` for determinism, note in the migration comment that it never guaranteed identical outputs.

```python
# Before
client.messages.create(model="claude-sonnet-4-6", temperature=0.2, ...)

# After -- omit entirely
client.messages.create(model="claude-sonnet-5", ...)
```

3. Bedrock only: forced `tool_choice` requires `thinking: {type: "disabled"}`. On Amazon Bedrock, pass `thinking: {type: "disabled"}` alongside `tool_choice: {type: "tool", name: ...}` or `tool_choice: {type: "any"}`. The Claude API and Vertex AI do not require this.

Not a request-shape error, but handle it: cybersecurity safeguards. Claude Sonnet 5 is substantially more cyber-capable than Sonnet 4.6, so -- like Opus 4.7/4.8 -- requests touching prohibited or high-risk topics may be refused. Handle it as a content outcome (see the `refusal` stop-reason guidance in the Claude Fable 5 section if the caller needs a fallback path).

Unchanged from Sonnet 4.6: assistant-turn prefills still return a 400 (use `output_config.format` or a system-prompt instruction); the 1M-token context window, the 128k max-output ceiling, prompt caching, batch processing, the Files API, PDF support, vision, and the full server- and client-side tool set all carry over.

Silent default change: adaptive thinking on when `thinking` is omitted

On Sonnet 4.6, a request with no `thinking` field runs **without** thinking. On Claude Sonnet 5, the same request runs with **adaptive thinking**. This is not an error -- but callers who never set `thinking` will now see thinking output (and spend thinking tokens) where they didn't before. `max_tokens` is a hard limit on total output (thinking + response text), so a workload that ran thinking-off on Sonnet 4.6 by omission may now truncate. Either set `thinking: {type: "disabled"}` explicitly to keep the old behavior, or revisit `max_tokens` to leave room for thinking.

Silent default change: `thinking.display` defaults to `"omitted"`

`thinking.display` defaults to `"omitted"` on Claude Sonnet 5 (matching Opus 4.7/4.8 and Claude Fable 5); on Sonnet 4.6 it defaulted to `"summarized"`. With the default, `thinking` blocks stream with empty text -- to a streaming UI this looks like a long pause before output. Combined with the adaptive-on-by-default change above, a Sonnet 4.6 caller who omits `thinking` entirely now gets adaptive thinking *and* empty-text thinking blocks. If you stream reasoning to users, set `thinking: {type: "adaptive", display: "summarized"}` explicitly. `display` controls visibility only -- thinking happens and is billed the same under every setting.

New tokenizer (~30% more tokens)

Claude Sonnet 5 uses the same new tokenizer as Opus 4.7/4.8. The same input text produces approximately 30% more tokens than on Sonnet 4.6. No request/response shape changes and no code edits are required, but **everything measured or budgeted in tokens shifts**: `usage` fields and `count_tokens()` results for the same text are higher, the 1M context window holds less text, and a `max_tokens` limit tuned for Sonnet 4.6 may truncate equivalent output. Per-token pricing is unchanged at the $3/$15 sticker (introductory $2/$10 per MTok applies through 2026-08-31), so the cost of an equivalent request can differ. Re-run `count_tokens()` against `claude-sonnet-5` rather than reusing counts measured against earlier models, and re-baseline cost dashboards before reacting to measured shifts.

Choosing an effort level on Claude Sonnet 5

`effort` defaults to `high` when not set (same as Sonnet 4.6 and Opus 4.8). Claude Sonnet 5 supports the full `low`/`medium`/`high`/`xhigh`/`max` range -- the first Sonnet-tier model with `xhigh`. **Keep the `high` default for most work and raise to `xhigh` for the hardest coding and agentic tasks**:

Level	When to use on Claude Sonnet 5
`max`	Tasks needing the absolute highest capability with no token constraint. Can deliver gains in some use cases but may show diminishing returns and is sometimes prone to overthinking -- test before committing
`xhigh`	The hardest coding and agentic use cases -- the recommended setting for those
`high`	The default; balances token usage and intelligence for most use cases
`medium`	Cost-saving step-down from the default -- comparable to Sonnet 4.6 at `high`
`low`	Short, scoped tasks and latency-sensitive workloads that aren't intelligence-sensitive (chat, simple lookups)

As a rough cross-model mapping when migrating: Claude Sonnet 5 at `medium` is comparable in intelligence to Sonnet 4.6 at `high`, and Claude Sonnet 5 at `high` is comparable to Sonnet 4.6 at `max`. When benchmarking, match by observed thinking length rather than effort name.

Claude Sonnet 5 **respects effort levels strictly, especially at the low end**. At `low` and `medium` it scopes its work to what was asked rather than going above and beyond -- good for latency and cost, but on moderately complex tasks at `low` there is some risk of under-thinking. If you observe shallow reasoning on complex problems, **raise effort to `high` or `xhigh` rather than prompting around it**. If you must keep effort at `low` for latency, add targeted guidance:

> *"This task involves multi-step reasoning. Think carefully through the problem before responding."*

Leave `max_tokens` headroom at `xhigh`/`max`. Set a large output token budget (up to the 128k cap, unchanged from Sonnet 4.6) so the model has room for thinking and tool calls. On long tasks, adaptive thinking can use a large share of the budget; if the budget is tight you may see a response that is almost entirely thinking followed by a truncated answer and `stop_reason: "max_tokens"` -- raise `max_tokens` or drop to `medium`. Because Claude Sonnet 5 uses the new tokenizer (~30% more tokens for the same text), `max_tokens` limits tuned for Sonnet 4.6 may truncate equivalent output.

Adaptive vs. disabled thinking

Leave adaptive thinking on. Claude Sonnet 5 calibrates thinking spend to task complexity; the small added latency is usually worth the quality gain. If the caller was running Sonnet 4.6 with thinking off, **try adaptive + `effort: "low"` first** rather than `thinking: {type: "disabled"}`.

The triggering behavior for adaptive thinking is steerable. If the model emits thinking blocks more often than wanted (which can happen with large or complex system prompts), prompt it directly -- and measure the effect on quality:

> *"Thinking adds latency and should only be used when it will meaningfully improve answer quality, typically for problems that require multi-step reasoning. When in doubt, respond directly."*

Conversely, if you're running hard workloads at `medium` and seeing under-thinking, the first lever is to raise effort; if you need finer control, prompt for it directly.

```
### Capability improvements

**Coding and agentic tasks.** The largest gains over Sonnet 4.6 are in coding and agentic tasks. Claude
Sonnet 5 performs well out of the box on existing Sonnet 4.6 prompts.

**High-resolution vision.** Claude Sonnet 5 is the first Sonnet-tier model with high-resolution image
support: maximum **2576 pixels on the long edge** (up from 1568px on Sonnet 4.6). High-res images can use up
to ~3x more image tokens than on Sonnet 4.6 (4784 vs 1568 tokens per image at the limit) -- if the added
fidelity isn't needed, downsample before sending to control token costs. No beta header or opt-in required.

**Computer use.** Supports the `computer_20251124` tool version (beta header `computer-use-2025-11-24`).
Capability works across resolutions up to the 2576px / 3.75MP maximum; sending screenshots at **1080p**
provides a good balance of performance and cost. For particularly cost-sensitive workloads, **720p** or
**1366x768** are lower-cost options with strong performance. Test to find the ideal settings for the use
case; experimenting with `effort` can also help tune behavior.

### Behavioral shifts (prompt-tunable)

None of these break code, but prompts tuned for Sonnet 4.6 may land differently. Claude Sonnet 5 follows
instructions closely, so small explicit directives close the gap.

**Response length and verbosity.** Claude Sonnet 5 calibrates response length to task complexity rather than
defaulting to a fixed verbosity -- usually shorter on simple lookups, longer on open-ended analysis. If a
product depends on a particular verbosity, tune the prompt. To decrease verbosity:

> *"Provide concise, focused responses. Skip non-essential context, and keep examples minimal."*

If you see specific kinds of verbosity (e.g. over-explaining), add targeted instructions to prevent them.
Positive examples showing the desired concision tend to be more effective than telling the model what not to
do.

**Tool use triggering.** Claude Sonnet 5 is more agentic than Sonnet 4.6 by default and will reach for tools
and run self-verification loops more readily. **With thinking disabled**, the model is less likely to reach
for tools or consider searching -- if the harness relies on tool calls with thinking off, add an explicit
nudge in the system prompt. `effort` is also a lever: `high` and `xhigh` show substantially more tool usage
in agentic search and coding. For scenarios where you want more tool use, also explicitly instruct when and
how to use the tools (e.g. if web-search is under-used, describe in the prompt why and how it should be
called).

**User-facing progress updates.** Claude Sonnet 5 provides regular, higher-quality updates to the user
throughout long agentic traces by default. If the harness has scaffolding to force interim status messages
("After every 3 tool calls, summarize progress"), **try removing it**. If the length or content of the
updates isn't well-calibrated to the use case, describe what they should look like in the prompt and provide
an example.

**More literal instruction following.** Claude Sonnet 5 interprets prompts literally and explicitly,
particularly at lower effort levels. It does not silently generalize an instruction from one item to another,
and it does not infer requests that weren't made. The upside is precision -- better for carefully tuned
prompts, structured extraction, and pipelines that need predictable behavior. If an instruction should apply
broadly, **state the scope explicitly** ("Apply this formatting to every section, not just the first one").
The same literalism means style/tone directives carried over from Sonnet 4.6 may now over-apply --
re-baseline holdover lines like "be concise" before keeping them.

**Tone and writing style.** Prose style on long-form writing may shift. If a product relies on a specific
voice, re-evaluate style prompts against the new baseline. For a warmer or more conversational voice:

> *"Use a warm, collaborative tone. Acknowledge the user's framing before answering."*

Because `temperature`/`top_p`/`top_k` are not accepted on Claude Sonnet 5, callers who previously relied on
`temperature` for stylistic variety must use system-prompt instructions instead.

**Code review harnesses.** A review harness tuned for an earlier model may initially see lower recall on
Claude Sonnet 5. This is likely a harness effect, not a capability regression: when a review prompt says
"only report high-severity issues" / "be conservative" / "don't nitpick," Claude Sonnet 5 follows that
instruction more faithfully than earlier models did -- it investigates just as thoroughly, identifies the
bugs, and then doesn't report findings it judges below the stated bar. Precision typically rises, but
measured recall can fall even though underlying bug-finding ability has improved. Recommended prompt language:

> *"Report every issue you find, including ones you are uncertain about or consider low-severity. Do not
filter for importance or confidence at this stage -- a separate verification step will do that. Your goal
```

```
here is coverage: it is better to surface a finding that later gets filtered out than to silently drop a real
bug. For each finding, include your confidence level and an estimated severity so a downstream filter can
rank them."*

This works even without an actual second step, but moving confidence filtering out of the finding stage often
helps. If you do want single-pass self-filtering, be concrete about where the bar is rather than using
qualitative terms like "important" -- e.g. "report any bugs that could cause incorrect behavior, a test
failure, or a misleading result; only omit nits like pure style or naming preferences." Iterate against a
subset of evals to validate recall/F1 gains.

**Design and frontend defaults.** Claude Sonnet 5 may settle into a consistent default visual style on
open-ended frontend and design briefs. Generic instructions ("don't use that color," "make it clean and
minimal") tend to shift it to a different fixed palette rather than producing variety. Two approaches work
reliably: **specify a concrete alternative** (the model follows explicit specs precisely -- give the palette,
typography, layout, and spacing), or **have the model propose options before building** (e.g. "Before
building, propose 4 distinct visual directions tailored to this brief -- bg hex / accent hex / typeface plus
a one-line rationale -- ask the user to pick one, then implement only that direction"). Because `temperature`
isn't accepted on Claude Sonnet 5, the propose-then-pick approach is the recommended way to get meaningfully
different design directions across runs. To steer away from generic AI-aesthetic patterns, a short directive
in the system prompt also helps:

> *"NEVER use generic AI-generated aesthetics like overused font families (Inter, Roboto, Arial, system
fonts), cliched color schemes (particularly purple gradients on white or dark backgrounds), predictable
layouts and component patterns, and cookie-cutter design that lacks context-specific character. Use unique
fonts, cohesive colors and themes, and animations for effects and micro-interactions."*

**Interactive coding products.** Token usage and behavior can differ between autonomous, asynchronous coding
agents (single user turn) and interactive, synchronous coding agents (multiple user turns). To maximize both
performance and token efficiency, use `effort: "xhigh"` or `"high"`, add autonomous features like an auto
mode, and reduce the number of human interactions required. Specify task, intent, and constraints upfront in
the first turn -- well-specified initial prompts maximize autonomy and intelligence while minimizing extra
token usage after user turns; ambiguous or progressively-revealed prompts tend to reduce token efficiency and
sometimes performance.

### Claude Sonnet 5 Migration Checklist

Every item is tagged: **`[BLOCKS]`** items cause a 400 error or truncated output if missed; **`[TUNE]`**
items are quality/cost adjustments -- surface them to the user as recommendations.

- [ ] **[BLOCKS]** Update the `model=` string to `claude-sonnet-5`
- [ ] **[BLOCKS]** Replace `thinking: {type: "enabled", budget_tokens: N}` with `thinking: {type:
"adaptive"}` + `output_config.effort` -- the Sonnet 4.6 transitional escape hatch is gone
- [ ] **[BLOCKS]** Strip `temperature`, `top_p`, `top_k` from request construction (use system-prompt
instructions for tone/variety instead)
- [ ] **[BLOCKS]** Bedrock only: pass `thinking: {type: "disabled"}` alongside forced `tool_choice` (`{type:
"tool"}` / `{type: "any"}`) -- not required on the Claude API or Vertex AI
- [ ] **[BLOCKS]** At `effort: "xhigh"` or `"max"`: set a large `max_tokens` (up to 128k, unchanged from
Sonnet 4.6) so the model has room for thinking and tool calls -- Sonnet-4.6-tuned limits may truncate
equivalent output under the new tokenizer (symptom: `stop_reason: "max_tokens"`)
- [ ] **[TUNE]** Thinking-field omitted: adaptive is now the default (4.6 ran thinking-off) -- either set
`thinking: {type: "disabled"}` to preserve the old behavior, or revisit `max_tokens` for the added thinking
spend
- [ ] **[TUNE]** `thinking.display` defaults to `"omitted"` (4.6 defaulted to `"summarized"`): if you stream
reasoning to users, set `thinking: {type: "adaptive", display: "summarized"}` explicitly -- the default
streams empty-text thinking blocks (long pause before output)
- [ ] **[TUNE]** New tokenizer: re-run `count_tokens()` against `claude-sonnet-5` (~30% more tokens for the
same text); revisit `max_tokens` and compaction triggers sized close to expected output length; re-baseline
cost dashboards before reacting (per-token pricing unchanged)
- [ ] **[TUNE]** Effort: keep the `high` default; raise to `xhigh` for the hardest coding/agentic tasks;
`medium` is a cost-saving step-down (~= Sonnet 4.6 at `high`); reserve `low` for short, latency-sensitive,
non-intelligence-sensitive tasks. If shallow reasoning shows up at `low`/`medium`, raise effort rather than
prompting around it
- [ ] **[TUNE]** Thinking-off callers: try `thinking: {type: "adaptive"}` + `effort: "low"` instead of
`disabled`; if `disabled` must stay, add an explicit tool-triggering nudge (the model is less tool-eager with
thinking off)
- [ ] **[TUNE]** Tool usage: more agentic than 4.6 by default (reaches for tools and self-verification more
readily) -- `effort` is a lever (`high`/`xhigh` for more tool use); add explicit when/how triggering
instructions for under-used tools
- [ ] **[TUNE]** Drop forced progress-update scaffolding ("after every N tool calls, summarize") -- the
default updates are higher quality; describe the desired update shape if it still needs tuning
```

````
- [ ] **[TUNE]** Re-baseline holdover style/tone/scope directives -- instructions are followed literally; state the scope explicitly when one should apply broadly
- [ ] **[TUNE]** Verbosity-sensitive routes: tune response length via prompt (positive examples > "don't" instructions)
- [ ] **[TUNE]** Code-review harnesses with conservative-reporting instructions ("only high-severity", "don't nitpick"): switch to a coverage-first prompt (report everything with confidence + severity) and filter downstream -- measured recall can otherwise fall even though bug-finding improved
- [ ] **[TUNE]** Open-ended frontend/design briefs: specify a concrete spec, or have the model propose 3-4 visual directions and pick one (the recommended substitute for `temperature`-driven variety)
- [ ] **[TUNE]** Interactive coding products: use `effort: "xhigh"`/`"high"`, add autonomous features (e.g. auto mode), and put task/intent/constraints in the first turn
- [ ] **[TUNE]** Vision-heavy / computer-use pipelines: leave images at native resolution up to 2576px long edge for the accuracy gain (downsample to control image-token cost if fidelity isn't needed); for computer use, 1080p screenshots are a good performance/cost balance with `computer_20251124`
- [ ] **[TUNE]** Security workloads: add handling for safeguard refusals (cyber-capable topics may now be declined where Sonnet 4.6 answered)

---

## Migrating to Claude Fable 5

> **Model IDs `claude-fable-5` and `claude-mythos-5` are authoritative as written here.** When the user asks to migrate to Claude Fable 5, write `model="claude-fable-5"` exactly; a Mythos Preview migrator in Project Glasswing writes `model="claude-mythos-5"` (everyone else: `claude-fable-5`). Do **not** WebFetch to verify -- this guide is the source of truth for migration target IDs. The corresponding entries exist in `shared/models.md`.

Claude Fable 5 is Anthropic's most capable widely released model -- for the most demanding reasoning and long-horizon agentic work. **Claude Mythos 5** (`claude-mythos-5`) offers the same capabilities, pricing, and API behavior through Project Glasswing (participation is the only way to access it), and succeeds the invitation-only **Claude Mythos Preview** (`claude-mythos-preview`). Everything in this section applies to both models -- only the ID differs. Mythos Preview migrators in Project Glasswing target `claude-mythos-5`; everyone else targets `claude-fable-5`. 1M token context window by default (the maximum is also the default), up to 128K output tokens per request.

**Migrate to Claude Fable 5 only when the user explicitly chose it.** It is not the default Opus upgrade path -- pricing is above Opus-tier. For "upgrade to the latest model" requests, the target remains `claude-opus-5`.

### Breaking changes (vs Opus-tier and Mythos Preview)

1. **Thinking is always on -- remove all `thinking` configuration.** Adaptive thinking applies automatically whenever the `thinking` parameter is unset (an explicit `{type: "adaptive"}` is also accepted). Any other configuration is rejected: `thinking: {type: "disabled"}` and `{type: "enabled", budget_tokens: N}` both return a 400. `budget_tokens` has no replacement -- the `output_config.effort` parameter is a separate output-level control, not a thinking budget.

   ```python
   # Before (Mythos Preview / older models)
   client.messages.create(
       model="claude-mythos-preview",
       max_tokens=16000,
       thinking={"type": "enabled", "budget_tokens": 10000},
       messages=[...],
   )

   # After (Claude Fable 5) -- no thinking field at all
   client.messages.create(
       model="claude-fable-5",
       max_tokens=16000,
       output_config={"effort": "high"},
       messages=[...],
   )
   ```

2. **Assistant prefill is not supported.** Replace last-assistant-turn prefills with structured outputs (`output_config.format`) or system prompt instructions -- same replacement patterns as the 4.6-family prefill removal above. (One exception: the fallback-credit prefill claim -- the server accepts the echoed assistant message when redeeming a credit; see the refusal section below.)

3. **Interleaved scratchpad is not supported** (Mythos Preview migrators only). Inter-tool reasoning is
````

returned in thinking blocks instead, which adaptive thinking produces automatically between tool calls.

Thinking output on Claude Fable 5 and Claude Mythos 5

On Claude Fable 5 and Claude Mythos 5, the raw chain of thought is never returned. What you receive are **regular `thinking` blocks**, not encrypted blobs or `redacted_thinking`: `display: "summarized"` returns a readable summary of the reasoning, and with `"omitted"` -- the default, same as Opus 4.8/4.7 -- responses still include `thinking` blocks but the `thinking` field is an empty string. `display` controls visibility only; thinking happens and is billed the same under every setting. When continuing a conversation on the same model, pass thinking blocks back to the API **unchanged** (the standard multi-turn pattern; dropping or editing them breaks the turn).

When continuing on the same model, pass each thinking block back **exactly as received -- including blocks whose `thinking` text is empty**. The API rejects blocks whose content has been *modified*, not blocks you have read; displaying the summary is fine, editing or reconstructing blocks is not.

Regular thinking blocks aren't origin-locked -- they replay across models fine (the server renders them into the target model's prompt). Claude Fable 5/Claude Mythos 5 thinking is the exception: a thinking block from these models replayed to a different model is **dropped from the prompt** rather than rendered -- typically silently (early-access builds hard-rejected with `invalid_request_error`; that broke workflows and was reverted before launch, but the new behavior is still rolling out, so don't build logic that depends on either outcome). The drop happens before the prompt is priced, so a dropped block **lowers `usage.input_tokens`** -- you aren't billed for it, and there's nothing to strip for cost. Don't strip *regular* thinking blocks either: removing them can trigger ordering/signature 400s. Two rules for replay bodies stand regardless: fallback-credit retries must echo the refused body **unchanged**, and `fallback` blocks from a mid-output fallback stay where they appeared.

Related: a request that tries to elicit the model's internal reasoning *in the response text* can be refused with `stop_details.category: "reasoning_extraction"` -- applications needing reasoning visibility should read the summarized `thinking` blocks instead of prompting for reasoning.

Tokenizer -- unchanged from Opus 4.8

Claude Fable 5 uses the **same tokenizer as Claude Opus 4.8** (the tokenizer introduced with Opus 4.7). Token counts are roughly unchanged when migrating from Opus 4.7/4.8 or from `claude-mythos-preview`; per-token pricing differs.

- Coming **from Opus 4.7/4.8 or `claude-mythos-preview`**: token counts are roughly unchanged. Re-baseline cost and latency on your own workloads for the per-token price difference.
- Coming **from Opus 4.6, Sonnet, Haiku, or older**: the Opus 4.7 tokenizer tokenizes the same content to roughly 1x-1.35x as many tokens (varies by content and workload shape). Do not reuse token counts, context-window budgets, or `max_tokens` settings measured on the old model; re-baseline with `count_tokens`.

To measure the difference on your own prompts, call `count_tokens` once with your current model and once with `model: "claude-fable-5"`, and compare the two `input_tokens` values.

`refusal` stop reason -- handle before reading content

Claude Fable 5 runs safety classifiers on incoming requests, targeting research biology and most cybersecurity content (Claude Fable 5 is not intended for those domains); benign adjacent work -- security tooling, life-sciences tasks -- can occasionally trigger false positives, which is why the fallback patterns below matter even for legitimate workloads. (Most Claude consumer surfaces ship with built-in Opus 4.8 fallbacks; API callers configure their own.) A declined request returns a **successful HTTP 200** with `stop_reason: "refusal"`, plus a `stop_details` object with the policy category (values such as `"cyber"`, `"bio"`, `"reasoning_extraction"`, `"frontier_llm"`, or `null` -- treat `null` as a permanent valid state; see the refusal category table in the public docs for the full set). **Branch on `stop_reason`, never on `stop_details`** -- `stop_details` is informational and can be `null` even on a refusal, and `explanation` is not guaranteed present. Note that classifier blocks and ordinary model refusals (the model itself declining) both surface as `stop_reason: "refusal"`; `stop_details.category` tells you which class you're handling, and therefore whether retrying on a fallback model is the right response. The classifier can fire **before any output** (empty `content` array; not billed at all -- no input or output tokens, no rate-limit consumption) or **mid-stream** after partial output (already-streamed output is billed at normal rates -- discard the partial output rather than treating it as complete). Code that reads `response.content[0]` unconditionally will break -- check `stop_reason` first:

```python
response = client.messages.create(model="claude-fable-5", max_tokens=1024, messages=[...])
if response.stop_reason == "refusal":
    # classifiers declined; content is empty (pre-output) or partial (mid-stream)
    handle_refusal()
```

```
else:
    print(response.content[0].text)
```

Default to opting in. Fallbacks are not automatic on the API -- a request without them simply stops on a refusal. Migrated and new Claude Fable 5 code should ship with pattern 1 below (pattern 2 on providers without server-side support) from day one, not as a later hardening step: emit the opt-in in the code, tell the user it's there, and remove it only if they decline.

Three ways to retry a refused request on another model, in order of preference:

1. Server-side `fallbacks` parameter (beta; **Claude API only -- Claude Platform on AWS support is still being validated, so don't assume it) -- preferred.** One round trip, a plain client, no client-side logic. Name substitute models (the only supported fallback target at launch is `claude-opus-4-8`, expansion expected); on a policy decline the API runs the next model on the same request and returns its answer, with credit-style repricing applied automatically. A `stop_reason: "refusal"` on the final response means the whole chain refused.

```python
response = client.beta.messages.create(
    model="claude-fable-5",
    max_tokens=1024,
    betas=["server-side-fallback-2026-06-01"],
    fallbacks=[{"model": "claude-opus-4-8"}],
    messages=[{"role": "user", "content": "Hello, Claude"}],
)

# Switch points: one fallback block per model that ran and declined this turn
for block in response.content:
    if block.type == "fallback":
        print(f"{block.from_.model} declined; {block.to.model} continued")

# Served-by signal: a fallback_message in usage.iterations means a fallback model
# ran; pair it with stop_reason to confirm the fallback served the response
# (a fallback model can also refuse). Covers sticky turns too.
fallback_ran = any(
    entry.type == "fallback_message" for entry in response.usage.iterations or []
)
if fallback_ran and response.stop_reason != "refusal":
    print(f"Served by {response.model}")
```

Key semantics:

- **Header depends on the form you use.** The **array** form (`fallbacks: [{...}]`) requires exactly `server-side-fallback-2026-06-01` -- other `server-side-fallback-*` values reject it with a 400, and that header carries the *earliest* date of the series (`-2026-06-09` and `-2026-06-02` were earlier previews), so do not "correct" it to a newer-looking date. The **`"default"` scalar** form uses `server-side-fallback-2026-07-01` instead -- see ? New API features under Migrating to Claude Opus 5. Pairing either header with the other form 400s. Rejected on the Batches API; not available on Amazon Bedrock, Vertex AI, or Microsoft Foundry (use pattern 2 there -- the SDK middleware). Entries may override `max_tokens` per hop (bounding that attempt's own output independently of the top-level `max_tokens`); `thinking`, `output_config`, and `speed` overrides are rolling out (`speed` additionally requires its beta) -- until your requests accept them, include only `model` and `max_tokens` in each entry. Entries must be distinct and must be in the requested model's `allowed_fallback_models` (published on `/v1/models` when the `server-side-fallback-2026-06-01` beta header is set -- not yet visible under the `fallback-credit-*` header alone, and not exposed on Amazon Bedrock, Vertex AI, or Microsoft Foundry). The request *with an entry's overrides merged in* must be valid as a direct request to that entry's model.
- **Triggers on policy declines only** -- rate limits, overloads, and server errors on the requested model are returned as-is, never falling back.
- **Reading the response:** a `fallback` content block (`{"type": "fallback", "from": {"model": ...}, "to": {"model": ...}}`) marks each switch point in `content`; the served-by signal is a `fallback_message` entry in `usage.iterations` (don't rely on the block -- sticky-served turns have none). Top-level `model` names the model that produced the message.
- **Billing:** `usage.iterations` is the per-attempt source of truth; top-level `usage` covers only the attempt that produced the returned message. Declined-before-output attempts are reported but not billed; fallback attempts bill at the fallback model's rates. Each attempt claims the rate limits of the model that ran it -- if the fallback model is rate-limited or overloaded, the fallback attempt is not made and the preceding refusal is returned instead with `stop_details.recommended_model` naming a model to retry directly (the recommendation is a hint, not a guarantee, and is `null` when no recommendation is available) -- size

fallback-model limits for expected refusal volume.
- **Sticky routing:** once a conversation falls back, later non-streaming requests with `fallbacks` are served directly by the fallback model for ~1 hour (best-effort; org-scoped content-hash record, not message content; not recorded for ZDR orgs). Handle the requested model being tried again at any time.
- **Echoing fallback turns back:** after a mid-output fallback, omit `thinking`, `redacted_thinking`, and `tool_use` blocks -- plus any `server_tool_use` block without its matching `server_tool_result`, and any other unrecognized model-internal block type -- that appear *before* the final `fallback` block; text blocks, paired server-tool blocks, and everything after the boundary echo normally. The `fallback` block itself is an ignored audit marker (keep or drop). Streaming: the retry happens on the same stream and already-received content is never invalidated -- a pre-output block is seamless (`message_start` names the fallback model; the `fallback` block arrives as an ordinary `content_block_start`, first in `content` -- there is no special SSE event type; note `message_start` arrives only after the declined attempt, so time-to-first-byte includes it), and a mid-stream block keeps the partial, marks the boundary with the block, and continues -- only the partial's `text` blocks are passed to the fallback model as continuation context (other block types stay in `content` but aren't part of it). Sticky routing is **not consulted on streaming requests** in the initial release, so on streams the `fallback` block check is the complete signal; non-streaming mid-output declines omit the declined partial entirely.

2. SDK client-side middleware -- for providers without server-side fallbacks (Amazon Bedrock, Vertex AI, Microsoft Foundry). Register it on the client and every `client.beta.messages` request (streaming included) retries refusals automatically, splicing the fallback model's events onto the open stream in the same wire shape as pattern 1 (a `fallback` content block at each boundary, per-hop `usage.iterations`). It is also a beta surface: the middleware sends the `fallback-credit-2026-06-01` header by default so retries are repriced via credit tokens (override with its `betas` option). `BetaFallbackState` pins follow-up turns to the model that accepted (the client-side analog of sticky routing) -- reuse one state object per conversation:

```python
from anthropic import Anthropic, BetaFallbackState, BetaRefusalFallbackMiddleware

client = Anthropic(middleware=[BetaRefusalFallbackMiddleware([{"model": "claude-opus-4-8"}])])
state = BetaFallbackState()  # pins follow-ups to the model that accepted
with state:
    response = client.beta.messages.create(model="claude-fable-5", max_tokens=1024, messages=messages)
```

Create **one state per conversation** -- it is the pinning scope; sharing one across conversations pins unrelated threads together, and a conversation without a state is never pinned. Per-language naming (from the GA SDK examples -- don't improvise):

- **TypeScript**: `betaRefusalFallbackMiddleware([...])` in the client's `middleware` array; pass `{ fallbackState: state }` (a `BetaFallbackState`) as a request option.
- **Go**: `option.WithMiddleware(betafallback.BetaRefusalFallbackMiddleware([]anthropic.BetaFallbackParam{{Model: ...}}))` (package `lib/betafallback`); state via `betafallback.WithBetaFallbackState(&betafallback.BetaFallbackState{})` passed as a request option. Server-side equivalents: `Fallbacks: []anthropic.BetaFallbackParam{...}` + `anthropic.AnthropicBetaServerSideFallback2026_06_01`.
- **C#**: it's a *handler* -- `new AnthropicClient { Handlers = [new BetaRefusalFallbackHandler { Fallbacks = [new(Model.ClaudeOpus4_8)] }] }` (namespace `Anthropic.Helpers`); state via `BetaFallbackState.Create()` scoped per call with `using (fallbackState.Use()) { ... }`. Server-side equivalents: `Fallbacks = [new(Model.ClaudeOpus4_8)]` + `AnthropicBeta.ServerSideFallback2026_06_01`.

For languages not listed (Java, Ruby, PHP) -- or for a full runnable program in any language -- each public SDK repo ships a fallbacks example under `examples/` (e.g. `examples/fallbacks.py`, `examples/refusal-fallback/`): WebFetch the repo from `shared/live-sources.md` ? SDK Repositories rather than improvising the binding.

3. Hand-rolled retry + fallback credit (raw HTTP, or SDKs without the middleware). Detect the refusal via `stop_reason` and re-send the conversation as-is on a model with broader availability such as `claude-opus-4-8` (Claude Fable 5's thinking blocks are silently ignored by other models -- no stripping required); keep using the fallback model for subsequent turns. **Fallback credit** (beta: Claude API, Claude Platform on AWS, Amazon Bedrock, Vertex AI, and Microsoft Foundry) makes those retries cheaper. Prompt caches are per-model, so a plain retry pays cold cache-writes on the new model. With the `fallback-credit-2026-06-01` beta header (send it on both the original request and the retry), a refusal's `stop_details` carries `fallback_credit_token` (opaque; `null` when unavailable) and `fallback_has_prefill_claim`. Echo the token as the top-level `fallback_credit_token` request parameter on the retry (typed in the GA SDKs; on a pre-GA SDK pass it via `extra_body`) and the previously-cached span bills at cache-read rates -- the retry costs what it would have if the conversation had been on that model all along. Rules: the retry body must match the refused request **exactly** in every prompt-shaping field (`system`, `messages`, `tools`, `tool_choice`, `thinking` -- do **not** strip thinking blocks when redeeming

```
a credit -- the server handles them); the retry model must be in the refused model's
`allowed_fallback_models`; the token expires in 5 minutes; Batches results carry no tokens. If
`fallback_has_prefill_claim` is `true`, append one assistant message echoing the refused response's `content`
-- the retry model continues from where the refused model stopped (and completed server-tool work isn't
re-run). When echoing, strip trailing whitespace from a final `text` block (the prefill validator rejects it;
the credit match tolerates that edit), after omitting any unpaired `tool_use` blocks. On a 400, fall back to
the unchanged body with the token; on a 400 naming `fallback_credit_token`, retry without it (credit
forfeited).

**Migrating code built on the v1 preview.** If the code you're editing carries any of these markers, it
targets the discontinued early-access surface -- migrate it to the v2 shapes above, and ship the header and
parameter changes together (the v1 parameter shape under the v2 header is a 400):

| v1 marker (replace) | v2 |
|---|---|
| `server-side-fallback-2026-06-09` / `-2026-06-02` header | `server-side-fallback-2026-06-01` (array form;
the `"default"` scalar form uses `-2026-07-01`) |
| `fallback: {model, on_partial}` single object | `fallbacks: [{model, ...}]` array (1-3); `on_partial` no
longer exists -- partial-output behavior is fixed (streams keep the partial; non-streaming omits it). Unknown
keys in an entry are a 400 |
| Top-level `response.fallback` object (`from_model`, `reason`) | Never emitted -- read `fallback` content
blocks (switch points, no `reason` field) and `usage.iterations` (served-by) |
| `event: fallback` SSE with discard indices | No dedicated event; streamed content is never invalidated --
the switch arrives as an ordinary `content_block_start`/`stop` pair of type `fallback` |
| `fallback_primary` / `fallback_retry` iteration types | Blocked attempts are plain `message` entries; the
serving attempt is `fallback_message` |
| `reason: "sticky"` | No reason field -- sticky turns carry no block; detect via `fallback_message` in
`usage.iterations` + `response.model` |
| `recommended_model` meaning "primary served the refusal" | Now populated only when the fallback attempt
*couldn't run* (rate-limited/overloaded) -- its presence means a direct retry on that model may succeed, not
that it refused too |

### Data retention requirement

Claude Fable 5 requires **30-day data retention** and is not available under zero data retention. Requests
from an organization whose data-retention configuration doesn't meet the requirement return `400
invalid_request_error` -- if a migration suddenly 400s with no obvious request problem, check the org's
retention configuration before debugging the payload. On Amazon Bedrock, Google Vertex AI, and Microsoft
Foundry, data-retention requirements are set by each platform.

### What carries over unchanged

Same Messages API and tool-use patterns as Opus-tier and Mythos Preview. Supported at launch:
`output_config.effort` (`low`/`medium`/`high`/`xhigh`/`max`), Task Budgets (beta, `task-budgets-2026-03-13`
header), compaction (beta, `compact-2026-01-12` header), the memory tool, tool-call clearing via context
editing, and high-resolution vision (no downscaling cap, as on Opus 4.7+).

### Behavioral shifts (prompt-tunable)

None of these are API-breaking, but they're where migrated workloads feel different. Claude Fable 5's biggest
gains are on work *above* what prior models could do (long-horizon autonomous runs, first-shot
implementations of well-specified systems, end-to-end enterprise deliverables -- financial analysis,
spreadsheets, slides, docs -- code review/debugging and repository-history search, vision on dense or
degraded images -- it's explicitly trained to use bash and crop tools on flipped/blurry/noisy inputs --
navigating ambiguity, parallel sub-agent delegation and collaboration -- it reliably sustains ongoing
communications with long-running sub-agents and peer agents; note bug-finding gains exclude security-focused
analysis, where the cyber classifiers apply) -- don't evaluate it only on workloads older models already
handled.

**Longer turns by default -- the biggest structural shift.** Individual requests on hard tasks can run many
minutes at higher effort (a 15-minute single request is normal when the task involves gathering context,
building, and self-verifying). Before migrating, plan timeouts, streaming, and user-facing progress
indicators; structure work so callers check in on runs asynchronously rather than blocking inside one
request. On ambiguous tasks Claude Fable 5 may need a small nudge to avoid overplanning:

> When you have enough information to act, act. Do not re-derive facts already established in the
conversation, re-litigate a decision the user has already made, or narrate options you will not pursue in
user-facing messages. If you are weighing a choice, give a recommendation, not an exhaustive survey. This
does not apply to thinking blocks.
```

Consider all effort levels. `output_config.effort` is the primary intelligence/latency/cost control. Recommended defaults: `high` for most tasks, `xhigh` for the most capability-sensitive workloads, `medium`/`low` for routine work. Lower effort settings -- including `low` -- still perform very well on Claude Fable 5, often exceeding the `xhigh` or even `max` performance of previous models. Reduce effort if a task completes correctly but takes longer than necessary, or for a quicker interactive working style. At higher effort on routine work, Claude Fable 5 can gather context and deliberate beyond what the task needs (the flip side: higher effort buys excellent verification behavior and the most rigorous outputs). To prevent unrequested tidying or refactoring at higher effort:

> Don't add features, refactor, or introduce abstractions beyond what the task requires. A bug fix doesn't need surrounding cleanup and a one-shot operation usually doesn't need a helper. Don't design for hypothetical future requirements - do the simplest thing that works well. Avoid premature abstraction. Avoid half-finished implementations either. Don't add error handling, fallbacks, or validation for scenarios that cannot happen. Trust internal code and framework guarantees. Only validate at system boundaries (user input, external APIs). Don't use feature flags or backwards-compatibility shims when you can just change the code.

Instruction following is strong -- use it. Claude Fable 5 is very responsive to explicit communication-style sections in system prompts; invest in them rather than fighting output style downstream. Un-steered -- especially at higher effort -- it can elaborate beyond what the task needs: heavily-structured PR descriptions, sections on alternatives that weren't chosen, comments narrating what the next line does. You don't need to enumerate these behaviors by name; a brief instruction is just as effective:

> Lead with the outcome. Your first sentence after finishing should answer "what happened" or "what did you find" -- the thing the user would ask for if they said "just give me the TLDR." Supporting detail and reasoning come after. Being readable and being concise are different things, and readability matters more. The way to keep output short is to be selective about what you include (drop details that don't change what the reader would do next), not to compress the writing into fragments, abbreviations, arrow chains like A -> B -> fails, or jargon.

Ground progress claims on long runs. Require progress claims to be audited against tool results -- in testing this nearly eliminated fabricated status reports on tasks designed to elicit them:

> Before reporting progress, audit each claim against a tool result from this session. Only report work you can point to evidence for; if something is not yet verified, say so explicitly. Report outcomes faithfully: if tests fail, say so with the output; if a step was skipped, say that; when something is done and verified, state it plainly without hedging.

State boundaries explicitly. Claude Fable 5 sometimes takes unrequested-but-adjacent actions (e.g. composing an email straight to drafts, creating backup git branches). Define what it should *not* do:

> When the user is describing a problem, asking a question, or thinking out loud rather than requesting a change, the deliverable is your assessment. Report your findings and stop. Don't apply a fix until they ask for one. Before running a command that changes system state -- restarts, deletes, config edits -- check that the evidence actually supports that specific action. A signal that pattern-matches to a known failure may have a different cause.

Let it delegate -- asynchronously. Parallel sub-agents are dependable on Claude Fable 5 -- instead of suppressing delegation (a common prior-model guardrail), use sub-agents frequently and give explicit guidance on *when* delegation is desirable. Sub-agents that communicate **asynchronously** with the orchestrator outperform spawn-and-block: long-lived agents keep their context instead of re-establishing it per subtask (cache-read savings), the orchestrator isn't bottlenecked on the slowest sub-agent, and context persists across subtasks.

> Delegate independent subtasks to sub-agents and keep working while they run. Intervene if a sub-agent goes off track or is missing relevant context.

Give it a memory surface. Claude Fable 5 performs notably better when it can write learnings somewhere for future reference -- even a plain `.md` file. Tell it where, tell it to consult that file in future sessions, and give it a format:

> Store one lesson per file with a one-line summary at the top. Record corrections and confirmed approaches alike, including why they mattered. Don't save what the repo or chat history already records; update an existing note rather than creating a duplicate; delete notes that turn out to be wrong.

Rare: early stopping. Deep into long sessions it can occasionally end a turn with a text-only statement of intent ("I'll now run X") without the tool call, or ask permission it doesn't need. A "continue" recovers it interactively; for autonomous pipelines add a system reminder:

> You are operating autonomously. The user is not watching in real time and cannot answer questions mid-task, so asking 'Want me to...?' or 'Shall I...?' will block the work. For reversible actions that follow from the

````
original request, proceed without asking. Offering follow-ups after the task is done is fine; asking
permission after already discussing with the user before doing the work is not. Before ending your turn,
check your last paragraph. If it is a plan, an analysis, a question, a list of next steps, or a promise about
work you have not done ('I'll...', 'let me know when...'), do that work now with tool calls. End your turn
only when the task is complete or you are blocked on input only the user can provide.

**Rare: context anxiety.** In very long sessions it can worry about running out of context -- suggesting a
new session or trimming its own work -- most often when the harness surfaces a remaining-token countdown.
Avoid showing explicit context-budget counts; if you must:

> You have ample context remaining. Do not stop, summarize, or suggest a new session on account of context
limits - continue the work.

**Give the reason, not just the request.** Claude Fable 5 performs better when it understands the intent
behind a request -- it connects the task to relevant information rather than inferring intent on its own.
This matters most for long-running agents juggling context from disparate workstreams:

> I'm working on [the larger task] for [who it's for]. They need [what the output enables]. With that in
mind: [request].

**Readability in long agentic sessions.** Deep into extended conversations (many tool calls, large working
context) Claude Fable 5 can produce text users find hard to follow -- dense arrow-chain shorthand,
implementation-level detail, references to thinking the user never saw. A communication-style addendum
strongly mitigates this; adapt:

> Terse shorthand is fine between tool calls (that's you thinking out loud, and brevity there is good). Your
final summary is different: it's for a reader who didn't see any of that. If you've been working for a while
without the user watching - overnight, across many tool calls, since they last spoke - your final message is
their first look at any of it. Write it as a re-grounding, not a continuation of your working thread: the
outcome first, then the one or two things you need from them, each explained as if new. The vocabulary you
built up while working is yours, not theirs; leave it behind unless you re-introduce it. When you write the
summary at the end, drop the working shorthand. Write complete sentences. Spell out terms instead of
abbreviating them. Don't use arrow chains, hyphen-stacked compounds, or labels you made up earlier -- the
reader doesn't have the context to decode them. When you mention files, commits, flags, or other identifiers,
give each one its own plain-language clause saying what it is or what changed -- never pack several into one
parenthesized run or slash-separated list. Open with the outcome: one sentence on what happened or what you
found. Then the supporting detail. If you have to choose between short and clear, choose clear.

### Long-running agent recommendations

- **Make self-verification explicit.** For long-running builds, instruct it to establish and run its own
checking harness on a cadence ("Establish a method for checking your own work as you build; run it every
[interval], verifying against the specification with sub-agents"). Separate fresh-context verifier sub-agents
tend to outperform self-critique.
- **De-prescribe migrated prompts and skills.** Prompts and skills written for prior models are often too
prescriptive for Claude Fable 5 and *reduce* output quality. After migrating, A/B the workload with older
step-by-step scaffolding removed -- prefer stating the goal and constraints over enumerating the steps.
Claude Fable 5 is also good at updating skills on the fly from what it learns mid-task -- let it.
- **Start at the top of your difficulty range.** The teams with the best early-access outcomes gave it their
hardest unsolved problems first -- have it scope the problem, ask questions, then execute.
- **Add a `send_to_user` tool for verbatim mid-task delivery.** When an asynchronous agent must deliver
something the user sees *exactly as written* mid-run (a deliverable, a progress update with specific numbers,
a direct answer), give it a client-side tool whose input you render directly in the UI -- tool inputs are
never summarized, so content arrives intact. Return a simple acknowledgement as the tool result:

```json
{
  "name": "send_to_user",
  "description": "Display a message directly to the user. Use this for progress updates, partial results, or
content the user must see exactly as written before the task finishes.",
  "input_schema": {
    "type": "object",
    "properties": {
      "message": { "type": "string", "description": "The content to display to the user." }
    },
    "required": ["message"]
  }
}
```
````

```
For agents that only narrate routine progress, the model's default progress narration is typically adequate
without this tool.

### Claude Fable 5 Migration Checklist

- [ ] **[BLOCKS]** Update the `model=` string to `claude-fable-5` (`claude-mythos-5` for Mythos Preview
migrators in Project Glasswing)
- [ ] **[BLOCKS]** Remove `thinking: {type: "disabled"}` (errors on Claude Fable 5)
- [ ] **[BLOCKS]** Replace assistant prefill with structured outputs or system prompt instructions
- [ ] **[BLOCKS]** Confirm the org meets the 30-day data-retention requirement (ZDR orgs get `400
invalid_request_error` on every request)
- [ ] **[BLOCKS]** Remove all other `thinking` configuration (`{type: "enabled", budget_tokens: N}` returns a
400, same as on Opus 4.7/4.8); control depth with `output_config.effort` instead
- [ ] **[BLOCKS]** If thinking content is surfaced to users or stored in logs: add `thinking: {type:
"adaptive", display: "summarized"}` (the default is `"omitted"` -- otherwise the rendered text is empty)
- [ ] **[TUNE]** Re-baseline cost and latency on your own workloads -- token counts are roughly unchanged
from Opus 4.7/4.8 and Mythos Preview (same tokenizer); per-token pricing differs. Coming from Opus 4.6,
Sonnet, Haiku, or older, token counts differ -- use `count_tokens` with each model to compare
- [ ] **[TUNE]** Add `stop_reason == "refusal"` handling before reading `response.content` (pre-output: empty
+ unbilled; mid-stream: partial output billed -- discard); opt into a fallback by default -- server-side
`fallbacks` (Claude API only: `fallbacks: "default"` with `server-side-fallback-2026-07-01`, or the array
form with `server-side-fallback-2026-06-01`) where available, otherwise the SDK middleware or fallback credit
(`fallback-credit-2026-06-01`, exact body); a bare client-side replay (history as-is; other models drop
Fable's thinking blocks) is the floor, not the recommendation
- [ ] **[TUNE]** If you surfaced thinking text to users, plan for the thinking output change -- the raw chain
of thought is never returned; render the `display: "summarized"` summary (per the [BLOCKS] item above); pass
blocks back unchanged on the same model; other models drop them from the prompt (unbilled)
- [ ] **[TUNE]** Plan for minutes-long turns: timeouts, streaming, async check-ins, progress UX (see Behavior
changes above)
- [ ] **[TUNE]** Run an effort sweep including low/medium for routine workloads; add the no-tidying
instruction if higher effort produces unrequested refactors
- [ ] **[TUNE]** A/B with prior-model scaffolding removed -- over-prescriptive prompts/skills reduce Claude
Fable 5 output quality

---

## Verify the Migration

After updating, spot-check that the new model is actually being used. Replace `YOUR_TARGET_MODEL` with the
model string you migrated to (e.g. `claude-fable-5`, `claude-opus-5`, `claude-opus-4-8`, `claude-opus-4-7`,
`claude-sonnet-5`, `claude-sonnet-4-6`, `claude-haiku-4-5`) and keep the assertion prefix in sync:

```python
YOUR_TARGET_MODEL = "claude-opus-5"  # or "claude-opus-4-7", "claude-sonnet-5", "claude-sonnet-4-6",
"claude-haiku-4-5"
response = client.messages.create(model=YOUR_TARGET_MODEL, max_tokens=64, messages=[...])
assert response.model.startswith(YOUR_TARGET_MODEL), response.model
```

For rate-limit headroom changes, pricing, or capability deltas (vision, structured outputs, effort support),
query the Models API:

```python
m = client.models.retrieve(YOUR_TARGET_MODEL)
m.max_input_tokens, m.max_tokens
m.capabilities["effort"]["max"]["supported"]
```

See `shared/models.md` for the full capability lookup pattern.
</doc>

<doc path="shared/models.md">
Claude Model Catalog

Only use exact model IDs listed in this file. Never guess or construct model IDs -- incorrect IDs will
cause API errors. Use aliases wherever available. For the latest information, WebFetch the Models Overview
URL in `shared/live-sources.md`, or query the Models API directly (see Programmatic Model Discovery below).

Programmatic Model Discovery
```

For **live** capability data -- context window, max output tokens, feature support (thinking, vision, effort, structured outputs, etc.) -- query the Models API instead of relying on the cached tables below. Use this when the user asks "what's the context window for X", "does model X support vision/thinking/effort", "which models support feature Y", or wants to select a model by capability at runtime.

```python
m = client.models.retrieve("claude-opus-4-8")
m.id                  # "claude-opus-4-8"
m.display_name        # "Claude Opus 4.8"
m.max_input_tokens    # context window (int)
m.max_tokens          # max output tokens (int)

# capabilities is an untyped nested dict -- bracket access, check ["supported"] at the leaf
caps = m.capabilities
caps["image_input"]["supported"]                        # vision
caps["thinking"]["types"]["adaptive"]["supported"]      # adaptive thinking
caps["effort"]["max"]["supported"]                      # effort: max (also low/medium/high)
caps["structured_outputs"]["supported"]
caps["context_management"]["compact_20260112"]["supported"]

# filter across all models -- iterate the page object directly (auto-paginates); do NOT use .data
[m for m in client.models.list()
 if m.capabilities["thinking"]["types"]["adaptive"]["supported"]
 and m.max_input_tokens >= 200_000]
```

Top-level fields (`id`, `display_name`, `max_input_tokens`, `max_tokens`) are typed attributes. `capabilities` is a dict -- use bracket access, not attribute access. The API returns the full capability tree for every model with `supported: true/false` at each leaf, so bracket chains are safe without `.get()` guards. TypeScript SDK: same method names, also auto-paginates on iteration.

Raw HTTP

```bash
curl https://api.anthropic.com/v1/models/claude-opus-4-8 \
  -H "x-api-key: $ANTHROPIC_API_KEY" \
  -H "anthropic-version: 2023-06-01"
```

```json
{
  "id": "claude-opus-4-8",
  "display_name": "Claude Opus 4.8",
  "max_input_tokens": 1000000,
  "max_tokens": 128000,
  "capabilities": {
    "image_input": {"supported": true},
    "structured_outputs": {"supported": true},
    "thinking": {"supported": true, "types": {"enabled": {"supported": false}, "adaptive": {"supported":
true}}},
    "effort": {"supported": true, "low": {"supported": true}, ..., "max": {"supported": true}},
    ...
  }
}
```

### Model Descriptions
- **Claude Fable 5** -- Anthropic's most capable widely released model, for the most demanding reasoning and
long-horizon agentic work. Same API surface as Opus 4.7/4.8 with one new breaking change: an explicit
`thinking: {type: "disabled"}` returns a 400 -- omit the `thinking` parameter instead (thinking is always on;
the raw chain of thought is never returned -- summaries via `display: "summarized"`). Same tokenizer as Opus
4.8 (token counts roughly unchanged vs Opus 4.7/4.8). Safety classifiers may return `stop_reason: "refusal"`.
No assistant prefill. Requires 30-day data retention (not available under ZDR). $10/$50 per MTok; 1M context
window (default), 128K max output. See `shared/model-migration.md` -> Migrating to Claude Fable 5.
- **Claude Mythos 5** -- Same capabilities, pricing, limits, and API behavior as Claude Fable 5; only the
model ID differs. Available exclusively through Project Glasswing, where it joins (and succeeds) the
invitation-only Claude Mythos Preview (`claude-mythos-preview`). Use it only when the org participates in
Project Glasswing; otherwise use claude-fable-5.
- **Claude Opus 5** -- For complex agentic coding and enterprise work; a step-change over Claude Opus 4.8,
strongest on deep reasoning, agentic and long-horizon work, and test-time compute scaling, at half the cost
of Claude Fable 5 (Claude Fable 5 remains the highest-capability tier). Safety classifiers can return
`stop_reason: "refusal"` -- handle it before reading `content`. A drop-in upgrade at Opus 4.8's pricing
($5/$25 per MTok) with the same feature set. Thinking is on by default (omitting `thinking` runs adaptive;
`{type: "adaptive"}` is equivalent), and `thinking: {type: "disabled"}` is available only at effort `high` or
lower -- pairing it with `xhigh`/`max` returns a 400. Raw thinking tokens are never returned. Full effort
ladder through `max`; 512-token prompt-cache minimum (down from 1024 on Opus 4.8); fast mode on the Claude
API only. Elevated cybersecurity safeguards. Separate rate-limit bucket from the combined Opus 4.x pool. 1M
context window (default and maximum), 128K max output. See `shared/model-migration.md` -> Migrating to Claude
Opus 5.
- **Claude Opus 4.8** -- The most capable model in the Opus 4 series -- highly autonomous, state-of-the-art
on long-horizon agentic work, knowledge work, and memory; clearer, warmer writing. Same API surface as Opus
4.7 (adaptive thinking only; sampling parameters and `budget_tokens` removed). 1M context window at standard
API pricing (no long-context premium). See `shared/model-migration.md` -> Migrating to Opus 4.8 -- a 4.7 ->
4.8 move is a model-ID swap plus prompt re-tuning, no new breaking changes.
- **Claude Opus 4.7** -- Previous-generation Opus. Highly autonomous; strong on long-horizon agentic work,
knowledge work, vision, and memory. Adaptive thinking only; sampling parameters and `budget_tokens` removed.
1M context window. See `shared/model-migration.md` -> Migrating to Opus 4.7.
- **Claude Opus 4.6** -- Older Opus. Supports adaptive thinking (recommended), 128K max output tokens
(requires streaming for large outputs). 1M context window.
- **Claude Sonnet 5** -- The best combination of speed and intelligence in the Sonnet tier; near-Opus quality
on coding and agentic work. Adaptive thinking on by default (omitting `thinking` runs adaptive); manual
`budget_tokens` removed; non-default sampling parameters rejected. `effort` supports
`low`/`medium`/`high`/`xhigh`/`max`. New tokenizer (~30% more tokens for the same text vs Sonnet 4.6).
High-resolution vision (2576px). 1M context window, 128K max output. See `shared/model-migration.md` ->
Migrating to Claude Sonnet 5.
- **Claude Sonnet 4.6** -- Previous-generation Sonnet. Supports adaptive thinking (recommended). 1M context
window. 128K max output tokens.
- **Claude Haiku 4.5** -- Fastest and most cost-effective model for simple tasks.

## Legacy Models (still active)

| Friendly Name     | Alias (use this)    | Full ID                       | Status |
|-------------------|---------------------|-------------------------------|--------|
| Claude Opus 4.5   | `claude-opus-4-5`   | `claude-opus-4-5-20251101`    | Active |
| Claude Opus 4.1   | `claude-opus-4-1`   | `claude-opus-4-1-20250805`    | Deprecated (retires 2026-08-05 --
migrate to `claude-opus-5`) |
| Claude Sonnet 4.5 | `claude-sonnet-4-5` | `claude-sonnet-4-5-20250929`  | Active |

## Deprecated Models (retiring soon)

| Friendly Name     | Alias (use this)    | Full ID                       | Status     | Retires      |
|-------------------|---------------------|-------------------------------|------------|--------------|
| Claude Sonnet 4   | `claude-sonnet-4-0` | `claude-sonnet-4-20250514`    | Deprecated | TBD          |

## Resolving User Requests

When a user asks for a model by name, use this table to find the correct model ID:

| User says...                              | Use this model ID              |
|-------------------------------------------|--------------------------------|
| "fable", "most capable model"             | `claude-fable-5`                 |
| "most powerful"                           | `claude-fable-5`                 |
| "mythos", "mythos 5"                      | `claude-mythos-5` (Project Glasswing participants only;
otherwise use `claude-fable-5`) |
| "mythos preview"                          | `claude-mythos-5` (successor to `claude-mythos-preview` -- see
migration guide) |
| "opus"                                    | `claude-opus-5`                   |
| "opus 5"                                  | `claude-opus-5`             |
| "opus 4.8"                                | `claude-opus-4-8`              |
| "opus 4.7"                                | `claude-opus-4-7`              |
| "opus 4.6"                                | `claude-opus-4-6`              |
| "opus 4.5"                                | `claude-opus-4-5`              |
| "opus 4.1"                                | `claude-opus-4-1` (deprecated, retires 2026-08-05 -- suggest
`claude-opus-5`) |
| "opus 4", "opus 4.0"                      | `claude-opus-4-0` (deprecated -- suggest `claude-opus-5`) |
| "sonnet", "balanced"                      | `claude-sonnet-5`            |
| "sonnet 5"                                | `claude-sonnet-5`            |
| "sonnet 4.6"                              | `claude-sonnet-4-6`            |
| "sonnet 4.5"                              | `claude-sonnet-4-5`            |
| "sonnet 4", "sonnet 4.0"                  | `claude-sonnet-4-0` (deprecated -- suggest `claude-sonnet-5`) |
| "sonnet 3.7"                              | Retired -- suggest `claude-sonnet-5` |
| "sonnet 3.5"                              | Retired -- suggest `claude-sonnet-5` |
| "haiku", "fast", "cheap"                  | `claude-haiku-4-5`             |

# Platform Availability

Which features work on which provider platform. **This table is the single source of truth in this skill** --
per-feature sections elsewhere point here instead of restating availability. When writing code for a
third-party platform (Bedrock, Vertex, Foundry) or Claude Platform on AWS, check this table first; a feature
not supported there means use the first-party Claude API surface or a different approach.

Columns: **1P** = first-party Claude API, **P-AWS** = Claude Platform on AWS (Anthropic-operated, same-day
parity), **Bedrock** = Amazon Bedrock, **Vertex** = Google Cloud Vertex AI, **Foundry** = Microsoft Foundry.
? = GA, beta = beta, ? = not supported.

| Feature | 1P | P-AWS | Bedrock | Vertex | Foundry | Notes |
|---|---|---|---|---|---|---|
| Messages, streaming, tool use | ? | ? | ? | ? | ? | Core API |
| PDF input | ? | ? | ? | ? | beta | |
| Structured outputs / strict tool use | ? | ? | ? | ? | beta | |
| Adaptive thinking / effort | ? | ? | ? | ? | beta | |
| Extended thinking | ? | ? | ? | ? | beta | |

<doc path="shared/prompt-audit.md">
# Prompt Audit -- Finding and Removing Dated Prompting Patterns

> **If you arrived via `/claude-api prompt-audit`:** this is the right file. Execute the steps below in order
-- do not summarize them back to the user. Start with Step 0 (establish scope and target model), and finish
by producing both deliverables: the audit report (Step 5) and the proposed diff (Step 6).

Prompts, skills, and tool descriptions accumulate instructions tuned to older models: emphasis added because
an old model under-triggered, step-by-step scripts added because an old model planned poorly, format
scaffolds written before the API had structured outputs. Current Claude models follow instructions more
closely and more literally than the models much of this text was written for, so the leftover text is not
just wasted tokens -- specific outdated instructions actively degrade behavior (over-triggering,
over-planning, rigid responses in gray areas), while merely irrelevant text is comparatively harmless. The
audit's job is therefore to find **specific dated instructions**, not to make prompts shorter. "Every token
earns its place" is the frame; "make it short" is not.

**The audit produces two artifacts -- both, always:**

1. **An audit report**: every finding with its location (`file:line`), the pattern it matches, why it is
obsolete for the target model, and a confidence level.
2. **A proposed diff**: concrete edits for the findings that warrant them. Propose -- never apply edits
without the user's consent.

**Prime directive: distinguish cruft from load-bearing content.** A finding you cannot tie to a named pattern
below, with a reason grounded in the target model's documented behavior, is not a finding. When in doubt,
flag it in the report with low confidence and leave it out of the diff. Indiscriminate deletion is the one
way an audit makes things worse -- see "What not to flag" below, which is as binding as the pattern tables.
The inverse binds too: **an audit that finds nothing should change nothing** -- a clean surface is a valid
outcome, and an empty diff beats a manufactured one.

---

## Step 0: Establish scope and target model
```

```
**Before reading any file, establish two things -- from the request and the repository, not by asking.** This
audit is non-interactive by design: it runs the same way in a chat session, a CI job, or a batch migration,
so it states its assumptions and proceeds instead of pausing for confirmation. Both assumptions go at the top
of the report (Step 5), where the user can correct them by re-running with a narrower request.

1. **Scope.** Which files count as the prompt surface? If the user's request names a file, directory, or file
list, that is the scope. Otherwise the scope is the whole working directory's prompt surface -- everything
Step 1's inventory finds.
2. **Target model.** Cruft is relative to a model: a workaround that is load-bearing on one generation is
dead weight on the next. Resolve the target in this order: the model the request names; else the destination
of an in-progress migration the repository documents (vendor notes, migration docs, TODOs); else the newest
model the repository's own code or docs point at; else the current flagship generation of the provider the
code calls. If the audit is part of a migration, read `shared/model-migration.md` -> the per-target section
alongside this file, since every migration section's checklist is also a removal checklist.

## Step 1: Inventory the prompt surface

Find everything that reaches the model as text, not just the file named "prompt":

- **System prompts** and the code that assembles them (f-strings, template files, conditional sections)
- **Tool definitions** -- `description` fields and parameter descriptions in the `tools` array
- **Skill and rule files** -- `SKILL.md`, `CLAUDE.md`, `.cursorrules`-style rule files, agent instruction
files
- **Request-building code** -- model IDs, `thinking` configuration, sampling parameters, stop sequences,
prefill construction, retry logic, beta headers
- **Few-shot blocks and embedded examples**, wherever they live

List what you found before auditing it, so the user can correct the inventory.

## Step 2: Establish provenance

Where git history is available, `git blame` the prompt files. The question for every emphatic or prohibitive
line is: **which failure, on which model, did this prevent -- and does that failure still reproduce on the
target model?** Lines added as mitigations for a model that is no longer in use are presumptive removal
candidates; a line nobody can justify is suspect by default.

Prompts can also be dated by their idioms even without history. `<scratchpad>` / `<brainstorm>` tag
instructions, "think step by step", assistant-turn prefills, quotes-first extraction scaffolds, and ROLE ->
CONTEXT -> RULES -> EXAMPLES boilerplate all mark text written for much earlier Claude generations --
techniques that are now natively trained (thinking, calibrated refusals) or superseded by API features
(structured outputs). Idiom-dating alone is a flag-only signal (low confidence in the Step 5 rubric); it
earns medium or high only when paired with a reason grounded in the target model's documented behavior -- a
blame line tying the text to a retired model's era is the strongest form of that pairing.

## Step 3: Classify every line -- the deletion rule

For each instruction, ask one question: **could the model already know this?**

- **Keep what only the author knows**: the audience and product, environment facts, the quality bar, tool
contracts and mechanics, genuinely hard judgment calls, and the *reasons* behind constraints. This is
context, and context is never cruft.
- **Candidates for removal**: restatements of trained defaults ("be accurate and helpful"), behavior the
model already does unprompted (thoroughness, planning, tool use), and workarounds for failures the target
model no longer has.

A second distinction sharpens the first: is the line a **constraint on behavior** (deletion candidate -- test
it) or **context the model can't get elsewhere** (usually keep)? This check prevents the audit from becoming
a length contest: a naive shortening pass deletes exactly the highest-value words.

## Step 4: Scan for the anti-pattern groups

Work through the four groups. "Signals" rows are greppable -- run them over the inventory rather than
eyeballing.

### Group 1 -- Dated prompt text

#### 1a. Pressure language -- say exactly what you mean, at normal volume

Older, less steerable models genuinely needed forcefulness; current models are highly responsive to the
```

```
system prompt, so the same text over-applies. This cuts in **both directions**: inflated emphasis causes
over-triggering and rigid behavior, while leftover hedges ("try to", "if possible") are now read literally as
permission to under-deliver.

| Before (written for older models) | After (current models) |
|---|---|
| `CRITICAL: You MUST use this tool when...` | `Use this tool when...` |
| `IMPORTANT: NEVER do X` (several per prompt) | State the one or two real constraints plainly, with the
reason |
| `If in doubt, use [tool]` / `Default to [tool]` | *(delete, or)* `Use [tool] when it would improve X` |
| `Be thorough. Do not be lazy. Do not stop early.` | *(delete -- current models are proactive by default)* |
| `Try to include a summary if possible` (when it's required) | `Include a summary.` |
| `You have a tendency to over-X, so...` / `Don't be too verbose` | State the desired behavior: `Keep
responses to the length the question needs.` |

When several instructions are each marked critical, the markers stop carrying information -- and the prompt's
register becomes the output's register: an anxious prompt produces a cautious, hedging model. Emphasis is not
banned; it is a tested, scoped fix for one demonstrably underweighted instruction, not a first-draft register.

**Signals:** density of `MUST|NEVER|ALWAYS|CRITICAL|IMPORTANT` in caps; `!!`; emphasis with no adjacent
"because"; `try to|if possible|ideally` attached to actual requirements; `you (tend to|often|sometimes)`
trait claims; `don't be too [adjective]`.

#### 1b. Scaffolds replaced by API features -- replace, don't rewrite

These aren't tuned down; they're swapped for the feature that replaced them. For per-model specifics (what
errors on which model, exact syntax), read `shared/model-migration.md`.

| Scaffold in the prompt or request code | Replacement |
|---|---|
| "Think step by step", `<scratchpad>`/`<thinking>` tag instructions | Adaptive thinking (`thinking: {type:
"adaptive"}`) + `effort`. On thinking models the incantation is redundant at best; control depth via
configuration, not prose. |
| "Use the think tool to plan" / "plan before acting" | Delete -- current models plan without being told, and
these cause over-planning. If behavior is still too aggressive after cleanup, lower `effort` rather than
adding prose. |
| "Show your thinking" / required reasoning sections in the output | Read thinking blocks via the API. On
Claude Fable 5, instructing reasoning reproduction can trigger a `refusal` (reasoning extraction) -- this is
an explicit audit item when migrating. |
| Assistant-turn prefill (`{"role": "assistant", "content": "{"`) and the JSON-forcing stack around it:
stop-sequences, regex extraction, retry-on-parse loops, "output ONLY valid JSON" | Structured outputs
(`output_config.format`). Prefill 400s on 4.6-and-later Opus- and Sonnet-tier models and Claude Fable 5 --
confirm in the per-target section of `shared/model-migration.md` before claiming the error. Where it applies,
the *surrounding code* is cruft too -- audit the request builder, not just the prompt string. Only a
**trailing** assistant turn is a prefill -- partial or complete-looking (a few-shot block ending on the
assistant side still counts): assistant turns mid-array are ordinary conversation history and must stay. |
| "Summarize progress every N tool calls" choreography; hard word caps (`at most N words`) | Delete and
re-baseline: current models narrate appropriately, and output caps starve reasoning on hard problems. Prefer
qualitative length guidance ("be concise") over numeric caps tuned against an older model's verbosity. |
| Inline lookup tables, point systems, arithmetic rubrics the model must compute | Data in files or tool
results; arithmetic in code. Leave the model the judgment layer. |
| `budget_tokens`, non-default `temperature`/`top_p`/`top_k`, stale beta headers, dead 400-retry paths | See
`shared/model-migration.md` -- whether each one hard-errors or is merely deprecated depends on the target
model, so take the error claim from the per-target section there, not from memory. Where it does error, the
retry/workaround code around it is removable too. |

**Signals:** `think step by step|take a deep breath`; `<scratchpad>|<thinking>` in instructions;
`stop_sequences` guarding JSON; `json.loads` inside retry loops; `budget_tokens|temperature|top_p` in request
code; `every \d+ (tool calls|messages)`; `at most \d+ (words|sentences)`.

#### 1c. Over-specification -- describe the goal, not the method

| Pattern | Why it's cruft now | Fix |
|---|---|---|
| Step-by-step choreography for judgment tasks (`STEP 1: ... STEP 2: ...`) | Skills and prompts written for
prior models are often too prescriptive for current ones and degrade output quality -- the model's own plan
usually beats a hand-written script | State outcomes, constraints, and how to verify; keep numbered steps
only where order truly matters |
| Prohibition lists ("do not X, never Y, avoid Z...") | Describing success beats enumerating failure; a
prohibition against a failure the model wasn't going to make can *anchor it toward* that failure | Keep
```

prohibitions whose failure reproduces on the target model; rewrite the rest as positive statements of intent |
Example over-indexing: the single gold output; stale few-shot blocks	Concrete examples are the strongest signal in a prompt -- the model matches their length, tone, and structure, and examples written for an older model freeze that model's behavior into the new one	Several deliberately varied examples, labeled illustrative; delete examples of judgment the model already owns; keep examples that pin a genuinely format-sensitive output shape
Bullet walls and heavy formatting for behavioral guidance	Bullets flatten priority and sever rules from reasons, and prompt format bleeds into output format	Structure for reference data; prose for behavior, carrying the "because"
Padding: generic virtues ("be accurate, thorough, clear"), repetition as reinforcement, kitchen-sink edge cases, limits with escape hatches	The model treats everything as actionable signal; asides get applied where they don't fit; duplicated rules make the model spend effort reconciling wordings; bulk also directly inflates adaptive-thinking spend	Say it once, in the right place; cover the hard judgment calls instead of the easy parts
Grader and eval vocabulary ("you will be graded on...", "hidden tests")	Describes the scoring apparatus instead of the requirement and pushes effort toward being-watched	State every requirement the grader checks; never describe the grader
Strategy coaching next to task rules ("it's usually best to...")	The author's heuristics are wrong in some situations and the model's plan is usually better	If removing the sentence wouldn't change what is legal or how success is measured, it's strategy -- delete it

Signals: `STEP \d`/numbered imperatives for non-fragile work; runs of 3+ `Do not|Never|Avoid` lines; `do not hallucinate` (re-test whether you still need it -- removal here is low confidence, not a documented harm); single embedded gold outputs; near-duplicate sentences across sections; `Remember,|Again,|As stated above`; `grade|graded|rubric|hidden test`.

1d. Fossils -- text that outlived its model

Pattern	Why it's cruft now	Fix
Model-version workarounds: formatting fixes, over-refusal softeners, retry hints, "known issue with [model]" comments, date-conditional guidance	Nobody owns the removal, so prompts accumulate the union of every generation's mitigations	Each mitigation names (or gets traced to) the model it patched; if that model is retired, remove and re-test
Migration-relative phrasing: "X now works differently", "also counts", "no longer"	The text is a diff against a previous prompt version the model never saw; relative phrasing implies phantom alternatives	Write as if current rules are the only rules that ever existed
Patch accretion: many narrow conditionals, each traceable to one incident	The model navigates a maze of special cases instead of a coherent principle, and fails unpredictably between them; an eval win for adding a line on top of the stack is not evidence the stack should exist	Generalize the principle or fix the underlying context; test removals, not just additions
Unenforced instructions: rules no code path, eval, or reviewer checks -- visibly violated in the app's own transcripts	If nothing checks it and nobody noticed, it carries no signal -- and behavioral rules that could be hooks, allowlists, or schema validators are less reliable as prose	Enforce in code what can be enforced in code; delete what nothing enforces and nobody misses
Identity stubs standing in for context ("You are a helpful assistant")	A role line is fine as a one-sentence focus-setter; the defect is an identity statement *substituting* for audience, product, and quality bar	Don't flag a short role line; flag when it's the only context the prompt gives

Signals: retired model names in prompts or comments (`claude-2|claude-3|claude-instant|3\.5|3\.7`); `before|after [date]` conditionals; `now|no longer|instead of` attached to behavioral rules; rules whose reason nobody remembers; `^You are (a|an) (helpful|expert)` with nothing task-specific following.

1e. Prohibition clusters -- judge by provenance, not by whether the model "needs it"

A run of unconditional "never / don't / must not" lines is audited by asking, for each, **does it carry a stated reason or encode a real business/policy constraint?** -- not "does the target model still need this guardrail?" (the latter question keeps everything, because nothing is *harmful* to say). Prohibitions that encode observable constraints (refund caps, data rules, compliance language, promises the business must not make) stay, ideally with their reason beside them. Prohibitions that merely describe an undesirable *output style* with no provenance -- banned phrases, tic lists, "don't start with 'Certainly'" written against an older model's habits -- are cruft: restate the desired style positively in one line, or attach the real reason if there is one. A surrounding cluster of legitimate reasoned prohibitions does not launder the no-provenance ones mixed into it; classify each line separately.

1f. Output-shaping choreography -- one pattern, remove every limb

Fixed interim-update cadences ("after every third tool call, post a progress note"), numeric output ceilings ("under 120 words", "at most five bullets"), and cut-the-detail instructions are manifestations of the **same** over-constraint pattern, written for models that padded or rambled. They are removed *together*: a

stated operational reason ("queue throughput", "supervisors skim") does not convert a numeric clamp into a keeper -- re-express the goal as audience/outcome framing without the number ("replies are scan-able and answer only what was asked"), and keep any genuinely format-sensitive requirement as a format instruction, not a word count. Removing the cadence while keeping the ceilings leaves the pattern in place.

Group 2 -- Brittle skill files

Skill files (`SKILL.md`, `CLAUDE.md`, rule files) inherit everything in Group 1, plus failure modes of their own. Skill size is a tax paid on every trigger.

Pattern	Why it's cruft now	Fix
Verbose SKILL.md explaining things the model already knows	Every paragraph must justify its token cost; general programming knowledge doesn't	Apply the Step 3 deletion rule paragraph by paragraph
Wrong degrees of freedom	Exact scripts for judgment calls over-constrain; vague prose for fragile operations under-constrains	Match specificity to fragility: prose heuristics for open fields, exact commands (`do not modify this command`) only for narrow bridges
The recency trap: one session's stumble encoded as a permanent rule	The next session steps around a pothole that isn't there	Before keeping a rule, ask: would this have helped most recent sessions, or just the one that wrote it?
Volatile specifics: hardcoded paths, flags, version numbers, API claims with no verification date	Skills rot factually as code ships; nothing re-checks them by default	Encode architecture, data models, and workflows; verify surviving factual claims against current code as part of the audit
Time-sensitive content ("if before [date]...", option menus, duplicated info across SKILL.md and reference files)	Dates rot; menus of alternatives dilute; duplicates drift apart	An "old patterns" section instead of dates; one default plus an escape hatch; information lives in exactly one place
History narratives: past tense, incident IDs, PR numbers, pinned model names	A rule's authority is the behavior it prescribes, not the incident that motivated it; pinned model names silently degrade after the next release	State the current rule; drop the archaeology
Trigger-case enumeration: description lists of near-synonymous example queries, growing one phrase per missed trigger	Descriptions ride in every request; enumeration taxes every token budget and generalizes worse than intent categories	Name generalized categories of intent; see Group 3 for the trigger/behavior split

Signals: `SKILL.md` not readable in one sitting; hardcoded paths and version pins; past tense in instruction files; descriptions that only ever grow in git history.

Group 3 -- Tool descriptions

The rubric for tool descriptions is precision and contract accuracy, not brevity -- this is where a "trim it" instinct most often points the wrong way. Detailed descriptions are by far the most important factor in tool performance, and the most common failure is *under*-description. What changed on current models is *which content* belongs there: contract and mechanics in, behavioral steering and worked examples out. A tool description is a man page -- what the tool does, when to use it (and when not to), what each parameter means, caveats, what it does not return.

Pattern	Direction	Fix
Vague one-liners; parameters without descriptions; no when-not-to-use	**Under-described -- add**	3-4+ sentences minimum; description must precisely match actual behavior (a contract/behavior mismatch sends the model down paths no prompt text can fix)
`CRITICAL: You MUST use this tool when...`	Over-steered -- dial back	Plain `Use this tool when...` -- triggering boosters written against under-triggering models now cause over-triggering
Worked examples, fake dialogue turns, embedded protocols (numbered workflows, HEREDOCs) in the description -- in any quantity, even ones that "measurably lift the call rate"	Misplaced -- move	Examples constrain the exploration space and cost tokens on every request; move teaching material to skills/progressive disclosure; make parameters expressive (well-named enums carry intent)
Scolding cross-references (`ALWAYS use X, NEVER use Y for this`) and behavior-smuggling ("after showing results, always recommend...")	Misplaced -- move or delete	A description is a contract about functionality, not a channel for conversational instructions; put a preference for tool X in X's description, not scattered across its rivals
Tool names in the system prompt; prose lists that shadow the real tool list	Duplicated -- delete	The system prompt shouldn't name tools; then enabling or disabling one never leaves a dangling reference. Don't expose tools that are invalid in the current configuration
Near-duplicate overlapping tools; bloated response payloads; full catalogs of 30+ always-loaded tools	Structural	Fewer, clearly bounded tools with explicit boundaries in both descriptions; high-signal responses; past a few dozen tools use tool search / deferred loading instead of always-loading every schema

One deliberate split: trigger text is not behavioral text. Text whose job is routing -- a skill's frontmatter `description`, a trigger block -- may legitimately carry calibrated urgency, because skills

```
currently under-trigger; ideally it's tuned against a trigger eval rather than vibes. Text whose job is
behavior should explain rather than shout. These look identical to a grep, so classify by function before
flagging.

**Signals:** descriptions under ~3 sentences (add); `MUST|ALWAYS|NEVER` steering behavior inside descriptions
(dial back); fake dialogue or worked examples in descriptions (move); tool names in system-prompt prose
(delete).

### Group 4 -- Request config and architecture

The same audit keeps surfacing these next to prompt cruft; report them even though they're not prompt text.

- **API fossils**: parameters and headers that error or are deprecated on the target model -- the per-model
lists live in `shared/model-migration.md`; treat each migration checklist as a removal checklist.
- **Cache-hostile ordering**: timestamps, UUIDs, per-user content interpolated above stable content. Read
`shared/prompt-caching.md` -> Silent invalidators, and run its greps during this audit.
- **Budget countdowns rendered into context**: surfacing remaining-token counts to the model can cause
premature wrap-up behavior; avoid showing them where possible.
- **An LLM executor for a deterministic plan**: agent sessions whose transcript is the same loop body N
times; calls whose inputs fully determine outputs. **Run this check, don't wait to notice it**: in every
pipeline, batch job, or agent loop, *count the model-call sites* and ask of each whether its inputs fully
determine its output. Routing, tallying, normalizing, filtering, and formatting steps go back into plain
code; keep exactly one model call where the work is genuinely adaptive (classifying the ambiguous remainder,
writing the judgment summary). Zero model calls is an over-fix when a judgment step exists -- name the one
call that stays.
- **Redundant specialist sub-agents**: inspect the sub-agent roster / agent config as a surface in its own
right. Two agents doing the same task with the same tools and near-duplicate prompts, differing only in a
filter or a payload field, are one agent that should take the distinction as input. The fix is a concrete
roster edit -- delete the redundant definition and fold its one real difference into the surviving agent's
prompt or payload -- proposed as a diff like any other finding, not left as an advisory note.
- **No token accounting**: without per-surface cost visibility, every other issue here is invisible. If the
user has no accounting, recommend adding it first -- it's the prerequisite for measuring any cleanup.

---

## What not to flag -- the keep list

An audit that only says "delete" hurts the users who follow it most diligently. These stay, even when a grep
matches:

1. **Context is never cruft.** Audience, product, environment facts, quality bar, constraints, and the
*reasons* for them -- what only the author knows. Too-short prompts produce generic output because the model
fills gaps with safe defaults; give the model more context than seems necessary, not less.
2. **Cruft != length.** The harm comes from specific outdated instructions, not from volume. Never justify a
deletion by character count alone.
3. **Fragile operations keep exact scripts.** Low-freedom, prescriptive text is correct where exactly one
sequence is safe (destructive commands, auth flows, compliance steps). Prompting effort should scale with how
far the task is from what the model does naturally.
4. **Tool contract detail stays -- and often grows.** Parameter semantics, limits, failure modes, what the
tool does not return. The audit removes steering and examples from descriptions, not contract.
5. **Prohibitions against current, demonstrated failures stay.** The discriminator is whether the failure
reproduces on the target model in this context -- not whether the sentence pattern-matches "prohibition".
6. **Trigger/routing text may carry calibrated urgency** (see Group 3). Flag shouting in bodies, not
load-bearing trigger text.
7. **Format-pinning examples on genuinely format-sensitive outputs stay**, labeled illustrative.
8. **Working redundancy is not cruft.** Duplicated or overlapping content that is *functioning* -- the same
contract stated in two files, a worked example the prompt could in principle do without, content you would
merely organize differently -- is a refactoring preference, not a dated pattern. If it isn't causing errors
and the target model reconciles it, an audit leaves it alone; propose deduplication or consolidation only
when the duplicates actually disagree. "An audit that finds nothing should change nothing" extends to this:
on a clean surface, report that it is clean.
9. **A one-line role statement is fine.** Flag identity text only when it substitutes for real context.
10. **Deliberate recap is not padding.** A single end-of-prompt restatement of the few key constraints is a
known, reasonable pattern; the anti-pattern is scattered duplication.
11. **Re-baselining adds text too.** Matching a prompt to a new model sometimes means *adding* guidance for
the new model's failure modes (see the per-target "Behavioral shifts" sections in
`shared/model-migration.md`). The audit's job is fit, in both directions.

---
```

```
## Step 5: Produce the audit report

One entry per finding, in this shape:

| Field | Content |
|---|---|
| **Location** | `file:line` (or `file:line-range`) |
| **Evidence** | The exact text, quoted |
| **Pattern** | The group/row above it matches |
| **Why obsolete** | One or two sentences tying it to the target model's documented behavior ("current models
are proactive by default; this booster now causes over-triggering") |
| **Confidence** | **High** -- documented in current Claude docs or errors on the target model. **Medium** --
consistent, widely-observed behavior (e.g. example over-indexing). **Low** -- heuristic or idiom-dating;
flag, don't edit. |
| **Action** | `remove` / `rewrite` (give the replacement) / `move` (say where) / `replace-with-API-feature`
/ `add` (under-description -- the fix is *more* text; give it) / `flag` (no edit proposed) |

Order the report by confidence, highest first. Summarize at the top: counts per group, and the two or three
highest-impact findings in prose. Findings you cannot tie to a pattern and a target-model reason go at the
bottom as `flag` items or not at all.

**The flag-versus-fix threshold.** A finding that matches a documented row in the groups above *is* a high-
or medium-confidence finding, and it gets a concrete proposed action -- `remove`, `rewrite` (with the
replacement text), `move`, or `add`. `flag` is reserved for two things only: low-confidence idiom-dating that
no row documents, and items outside the audit's scope. Do not downgrade a documented-pattern match to `flag`
because it "seems minor," "reads as a soft nudge," "is a product judgment," or "measurably helps" -- those
are reasons the user may *decline* your proposed fix, not reasons to withhold it. An audit that correctly
identifies the pattern and then proposes nothing has done half the job; the user can always reject a hunk
they disagree with, but they cannot accept a fix you never wrote.

## Step 6: Produce the proposed diff

- Include only findings with action `remove`/`rewrite`/`move`/`replace-with-API-feature`/`add` at **high or
medium confidence**. `flag` and low-confidence items appear in the report only.
- One finding per hunk, so effects attribute and the user can take hunks selectively.
- Rewrites beat bare deletions where the instruction has a live purpose: re-express it simply ("look before
you delete") rather than keeping the verbose original or dropping the concern.
- A removal is complete only when everything referencing it goes too: tests asserting the old behavior, call
sites and helper functions, docs, and every model-ID pin (READMEs and rule files included). Grep the project
for the removed symbols and the old model ID before calling the diff done -- a prompt fixed while its smoke
test still asserts the old behavior is a broken app, not an audit win.
- For request-construction patterns (assistant-turn prefill, stop-sequence scaffolding, sampling-parameter
fossils), the diff must *eliminate the capability* on every code path -- after the fix, no path through the
request builder can still emit the dated shape (e.g. no reachable branch yields a trailing assistant turn) --
not merely rewire its current consumer. Include every call site of the changed function and the parser/retry
helpers that existed only to serve the old mechanism, and rewrite the tests that assert the old request shape.
- The report and the proposed diff are the deliverables -- produce both in full and stop there. Do not pause
mid-audit to ask whether to continue, and do not end by asking whether to apply: present the diff and let the
user take hunks on their own schedule. Apply edits to files only when the request itself explicitly asked for
the changes to be applied (e.g. "clean it up", "remove the cruft"), and even then keep `flag`/low-confidence
items out of the applied set.

## Step 7: Verify -- removal is a hypothesis, not a conclusion

- **Probe behavior, not self-report.** For each contested change, run a small behavioral check before and
after on a scratch copy (the user's eval suite if one exists; otherwise construct a minimal probe that
exercises the instruction's purpose). Asking the model whether it needs an instruction is not a measurement.
- **One change at a time** where stakes are high, so regressions attribute to their cause.
- **If a cut regresses, re-add simply.** Re-express the instruction in its minimal form and re-probe -- don't
restore the verbose original.
- **Check out-of-band dependencies before deleting.** Grep the wider system for the exact prompt text first
-- classifiers, tests, and log parsers sometimes match on prompt strings.
- **Re-audit at every model release.** Prompts are per-model artifacts; a line that is load-bearing on one
generation is cruft on the next. Each new migration section in `shared/model-migration.md` is the trigger to
run this audit again.
</doc>

<doc path="shared/prompt-caching.md">
# Prompt Caching -- Design & Optimization
```

````
This file covers how to design prompt-building code for effective caching. For language-specific syntax, see
the `## Prompt Caching` section in each language's README or single-file doc.

## The one invariant everything follows from

**Prompt caching is a prefix match. Any change anywhere in the prefix invalidates everything after it.**

The cache key is derived from the exact bytes of the rendered prompt up to each `cache_control` breakpoint. A
single byte difference at position N -- a timestamp, a reordered JSON key, a different tool in the list --
invalidates the cache for all breakpoints at positions >= N.

Render order is: `tools` -> `system` -> `messages`. A breakpoint on the last system block caches both tools
and system together.

Design the prompt-building path around this constraint. Get the ordering right and most caching works for
free. Get it wrong and no amount of `cache_control` markers will help.

---

## Workflow for optimizing existing code

When asked to add or optimize caching:

1. **Trace the prompt assembly path.** Find where `system`, `tools`, and `messages` are constructed. Identify
every input that flows into them.
2. **Classify each input by stability:**
   - Never changes -> belongs early in the prompt, before any breakpoint
   - Changes per-session -> belongs after the global prefix, cache per-session
   - Changes per-turn -> belongs at the end, after the last breakpoint
   - Changes per-request (timestamps, UUIDs, random IDs) -> **eliminate or move to the very end**
3. **Check rendered order matches stability order.** Stable content must physically precede volatile content.
If a timestamp is interpolated into the system prompt header, everything after it is uncacheable regardless
of markers.
4. **Place breakpoints at stability boundaries.** See placement patterns below.
5. **Audit for silent invalidators.** See anti-patterns table.

---

## Placement patterns

### Large system prompt shared across many requests

Put a breakpoint on the last system text block. If there are tools, they render before system -- the marker
on the last system block caches tools + system together.

```json
"system": [
  {"type": "text", "text": "<large shared prompt>", "cache_control": {"type": "ephemeral"}}
]
```

### Multi-turn conversations

Put a breakpoint on the last content block of the most-recently-appended turn. Each subsequent request reuses
the entire prior conversation prefix. Earlier breakpoints remain valid read points, so hits accrue
incrementally as the conversation grows.

```json
// Last content block of the last user turn
messages[-1].content[-1].cache_control = {"type": "ephemeral"}
```

### Shared prefix, varying suffix

Many requests share a large fixed preamble (few-shot examples, retrieved docs, instructions) but differ in
the final question. Put the breakpoint at the end of the **shared** portion, not at the end of the whole
prompt -- otherwise every request writes a distinct cache entry and nothing is ever read.

```json
"messages": [{"role": "user", "content": [
````
````

```
  {"type": "text", "text": "<shared context>", "cache_control": {"type": "ephemeral"}},
  {"type": "text", "text": "<varying question>"}  // no marker -- differs every time
]}]
```

Mid-conversation system messages

Claude Opus 5, Claude Opus 4.8, Claude Fable 5, and Claude Mythos 5; no beta header. Not available on Claude Sonnet 5 -- use top-level `system` there. (Sources conflict on Claude Sonnet 5: the model config marks it supported, but every canonical docs page omits it. Treat it as unsupported and catch the 400.) When an operator instruction arrives mid-conversation -- a mode switch, updated context, dynamically injected state -- send it as `{"role": "system", "content": "..."}` appended to `messages[]`, rather than editing top-level `system`. Editing top-level `system` changes the prefix ahead of the entire conversation history, so every cached turn is re-processed uncached; a `role: "system"` message sits after the history and leaves the cached prefix intact.

```json
// Top-level system stays byte-identical; new instruction goes after the cached history
"system": [{"type": "text", "text": "<stable core>", "cache_control": {"type": "ephemeral"}}],
"messages": [
  ...history,
  {"role": "user", "content": "..."},
  {"role": "system", "content": "Terse mode enabled -- keep responses under 40 words."}
]
```

This is also the prompt-injection-safe replacement for embedding operator instructions as text inside a user turn (the `<system-reminder>` pattern): both have the same caching profile, but `role: "system"` is the non-spoofable operator channel, whereas text inside user/tool content can be forged by anything that writes to user-visible input.

Must follow a `role: "user"` message (or an `assistant` message ending in server-tool use), and must be either the last entry in `messages` or be followed by an `assistant` turn; cannot be `messages[0]` -- use top-level `system` for the initial prompt. Content is text-only. Unsupported models return a 400 (`BadRequestError`: `role 'system' is not supported on this model`); catch that error and fall back to putting the instruction in a user-turn `<system-reminder>` block.

Prompts that change from the beginning every time

Don't cache. If the first 1K tokens differ per request, there is no reusable prefix. Adding `cache_control` only pays the cache-write premium with zero reads. Leave it off.

Architectural guidance

These are the decisions that matter more than marker placement. Fix these first.

Keep the system prompt frozen. Don't interpolate "current date: X", "mode: Y", "user name: Z" into the system prompt -- those sit at the front of the prefix and invalidate everything downstream. Inject dynamic context later in `messages` instead -- as a `{"role": "system", ...}` message where supported (see ? Mid-conversation system messages above), or as text in a user message otherwise. A message at turn 5 invalidates nothing before turn 5.

Don't change tools or model mid-conversation. Tools render at position 0; adding, removing, or reordering a tool invalidates the entire cache. Same for switching models (caches are model-scoped). If you need "modes", don't swap the tool set -- give Claude a tool that records the mode transition, or pass the mode as message content. Serialize tools deterministically (sort by name).

Fork operations must reuse the parent's exact prefix. Side computations (summarization, compaction, sub-agents) often spin up a separate API call. If the fork rebuilds `system` / `tools` / `model` with any difference, it misses the parent's cache entirely. Copy the parent's `system`, `tools`, and `model` verbatim, then append fork-specific content at the end.

Silent invalidators

When reviewing code, grep for these inside anything that feeds the prompt prefix:

```
| Pattern | Why it breaks caching |
|---|---|
| `datetime.now()` / `Date.now()` / `time.time()` in system prompt | Prefix changes every request |
| `uuid4()` / `crypto.randomUUID()` / request IDs early in content | Same -- every request is unique |
| `json.dumps(d)` without `sort_keys=True` / iterating a `set` | Non-deterministic serialization -> prefix
bytes differ |
| f-string interpolating session/user ID into system prompt | Per-user prefix; no cross-user sharing |
| Conditional system sections (`if flag: system += ...`) | Every flag combination is a distinct prefix |
| `tools=build_tools(user)` where set varies per user | Tools render at position 0; nothing caches across
users |

Fix by moving the dynamic piece after the last breakpoint, making it deterministic, or deleting it if it's
not load-bearing.

---

## API reference

```json
"cache_control": {"type": "ephemeral"}              // 5-minute TTL (default)
"cache_control": {"type": "ephemeral", "ttl": "1h"} // 1-hour TTL
```

- Max **4** `cache_control` breakpoints per request.
- Goes on any content block: system text blocks, tool definitions, message content blocks (`text`, `image`,
`tool_use`, `tool_result`, `document`).
- Top-level `cache_control` on `messages.create()` auto-places on the last cacheable block -- simplest option
when you don't need fine-grained placement.
- Minimum cacheable prefix is model-dependent. Shorter prefixes silently won't cache even with a marker -- no
error, just `cache_creation_input_tokens: 0`:

Model	Minimum
Claude Opus 5, Claude Fable 5, Claude Mythos 5	512 tokens
Opus 4.8, Claude Sonnet 5, Sonnet 4.6, Sonnet 4.5, Opus 4.1, Opus 4, Sonnet 4	1024 tokens
Opus 4.7, Mythos Preview, Haiku 3.5	2048 tokens
Opus 4.6, Opus 4.5, Haiku 4.5	4096 tokens

The minimum is not monotonic across generations -- 512 on the newest models, but 4096 on Opus 4.6/4.5 and
Haiku 4.5. A 3K-token prompt caches on Claude Opus 5, Opus 4.8, and Sonnet 4.5, and silently won't on Opus
4.6 or Haiku 4.5. Claude Opus 5 halves the Opus 4.8 minimum (1024 -> 512), so prompts previously too short to
cache now create entries with no code change.

These minimums apply on **every** platform where the model is available -- the old Amazon Bedrock override
for Claude Fable 5 was removed, and no per-platform exception remains.

Economics: Cache reads cost ~0.1x base input price. Cache writes cost **1.25x for 5-minute TTL, 2x for
1-hour TTL**. Break-even depends on TTL: with 5-minute TTL, two requests break even (1.25x + 0.1x = 1.35x vs
2x uncached); with 1-hour TTL, you need at least three requests (2x + 0.2x = 2.2x vs 3x uncached). The 1-hour
TTL keeps entries alive across gaps in bursty traffic, but the doubled write cost means it needs more reads
to pay off.

Verifying cache hits

The response `usage` object reports cache activity:

Field	Meaning
`cache_creation_input_tokens`	Tokens written to cache this request (you paid the ~1.25x write premium)
`cache_read_input_tokens`	Tokens served from cache this request (you paid ~0.1x)
`input_tokens`	Tokens processed at full price (not cached)

If `cache_read_input_tokens` is zero across repeated requests with identical prefixes, a silent invalidator
is at work -- diff the rendered prompt bytes between two requests to find it.

`input_tokens` is the uncached remainder only. Total prompt size = `input_tokens +
cache_creation_input_tokens + cache_read_input_tokens`. If your agent ran for hours but `input_tokens` shows
4K, the rest was served from cache -- check the sum, not the single field.
```

```
Language-specific access: `response.usage.cache_read_input_tokens` (Python/TS/Ruby),
`$message->usage->cacheReadInputTokens` (PHP), `resp.Usage.CacheReadInputTokens` (Go/C#),
`.usage().cacheReadInputTokens()` (Java).

---

## Invalidation hierarchy

Not every parameter change invalidates everything. The API has three cache tiers, and changes only invalidate
their own tier and below:

| Change | Tools cache | System cache | Messages cache |
|---|:---:|:---:|:---:|
| Tool definitions (add/remove/reorder) | ? | ? | ? |
| Model switch | ? | ? | ? |
| `speed`, web-search, citations toggle | ? | ? | ? |
| System prompt content | ? | ? | ? |
| `tool_choice`, images, `thinking` enable/disable | ? | ? | ? |
| Message content | ? | ? | ? |

Implication: you can change `tool_choice` per-request or toggle `thinking` without losing the tools+system
cache. Don't over-worry about these -- only tool-definition and model changes force a full rebuild.

**Two of these rows have a cache-preserving escape hatch**, each by moving the change out of the top-level
request and into a system message inside `messages[]`, after the cached prefix. **Availability differs per
row** -- the two are not gated together:

| Top-level change that invalidates | Cache-preserving form | Available on |
|---|---|---|
| Tool definitions (add/remove) | `tool_addition` / `tool_removal` blocks -- see
`shared/tool-use-concepts.md` ? Mid-conversation tool changes | Claude Opus 5 onward, behind
`mid-conversation-tool-changes-2026-07-01` |
| System prompt content | A `{"role": "system", "content": "..."}` message -- see ? Mid-conversation system
messages above | Claude Opus 5, Claude Opus 4.8, Claude Fable 5, Claude Mythos 5 -- **already available
today**, no beta header |

Model switch has no escape hatch: caches are model-scoped. Keep the main loop on one model and spawn a
subagent for cheaper sub-tasks (see `agent-design.md` ? Caching for Agents).

---

## 20-block lookback window

Each breakpoint walks backward **at most 20 content blocks** to find a prior cache entry. If a single turn
adds more than 20 blocks (common in agentic loops with many tool_use/tool_result pairs), the next request's
breakpoint won't find the previous cache and silently misses.

Fix: place an intermediate breakpoint every ~15 blocks in long turns, or put the marker on a block that's
within 20 of the previous turn's last cached block.

---

## Concurrent-request timing

A cache entry becomes readable only after the first response **begins streaming**. N parallel requests with
identical prefixes all pay full price -- none can read what the others are still writing.

For fan-out patterns: send 1 request, await the first streamed token (not the full response), then fire the
remaining N-1. They'll read the cache the first one just wrote.

## Pre-warming the cache

To eliminate the cache-miss latency on the *first* real request, send a **`max_tokens: 0`** request at
startup (or on an interval). The API runs prefill -- writing the cache at your `cache_control` breakpoint --
and returns immediately with `content: []`, `stop_reason: "max_tokens"`, and a populated `usage` block (zero
output tokens billed; normal cache-write charge on `cache_creation_input_tokens`).

**When to pre-warm** -- pre-warming trades a cache-write charge *now* for lower TTFT on the *next* real
request. It's worth it when all three hold: (a) first-request latency is user-visible (chat/voice/interactive
```

```
-- not background jobs), (b) the shared prefix is large enough that a cold write is noticeably slow, and (c)
there's a moment *before* traffic to fire it -- app startup, worker boot, post-deploy, start of a scheduled
window.

| Skip pre-warming when... | Because |
|---|---|
| Traffic is continuous (requests <= TTL apart) | The first real request warms the cache and every subsequent
one hits it; a separate warm call is a pure extra write |
| The prefix is small or below the cacheable minimum | The cold-write penalty is negligible |
| The prefix varies per request/user | Nothing shared to pre-warm |
| You'd pre-warm many distinct prefixes speculatively | Each is a ~1.25x write; cost can exceed the latency
you save |

**Scheduled re-warms:** only needed when traffic has gaps longer than the TTL. If real requests arrive more
often than every 5 minutes, they keep the cache warm on their own -- don't add an interval re-warm. For
bursty traffic with long idle gaps, either re-warm just under the TTL or switch to `ttl: "1h"` and re-warm
less often.

```python
client.messages.create(
    model="claude-opus-5",
    max_tokens=0,
    system=[{
        "type": "text",
        "text": SYSTEM_PROMPT,
        "cache_control": {"type": "ephemeral"},
    }],
    messages=[{"role": "user", "content": "warmup"}],
)
```

Breakpoint placement: put `cache_control` on the **last block shared with the real request** (the system
prompt or tool definitions) -- **not** on the placeholder user message, and **not** via top-level automatic
caching (which would key the cache to the placeholder). The placeholder can be any non-whitespace string;
it's read during prefill but never answered.

Rejected combinations: `max_tokens: 0` is an `invalid_request_error` with `stream: true`, `thinking.type:
"enabled"`, `output_config.format`, `tool_choice` of `{"type":"tool"}` or `{"type":"any"}`, or inside a
Message Batches request.

TTL still applies -- re-warm at least every 5 minutes for the default cache, or use the 1-hour TTL. This
replaces the older `max_tokens: 1` workaround (no single-token reply to discard, no output tokens billed,
intent is unambiguous).
</doc>

<doc path="shared/token-counting.md">
Token Counting

Use the `count_tokens` endpoint (`POST /v1/messages/count_tokens`) for accurate
token counts against Claude models. Token counts are **model-specific** -- pass
the same model ID you'll use for inference.

Do not use `tiktoken`. It's OpenAI's tokenizer. It undercounts Claude
tokens by ~15-20% on typical text, and by much more on code or non-English
input. Any estimate from `tiktoken`, `gpt-tokenizer`, or similar is wrong for
Claude.

Count a file or string

```python
from anthropic import Anthropic

client = Anthropic()
resp = client.messages.count_tokens(
    model="claude-opus-5",
    messages=[{"role": "user", "content": open("CLAUDE.md").read()}],
)
print(resp.input_tokens)
```
```

````
TypeScript: `await client.messages.countTokens({model, messages})` ->
`.input_tokens`. See `{lang}/claude-api/README.md` for other SDKs.

## CLI

```sh
ant messages count-tokens --model claude-opus-5 \
  --message '{role: user, content: "@./CLAUDE.md"}' \
  --transform input_tokens -r
```

## Diffing a file across two versions

The endpoint is stateless -- count each version separately and subtract:

```python
from anthropic import Anthropic
import subprocess

client = Anthropic()
def count(text: str) -> int:
    return client.messages.count_tokens(
        model="claude-opus-5",
        messages=[{"role": "user", "content": text}],
    ).input_tokens

before = subprocess.check_output(["git", "show", "HEAD:CLAUDE.md"], text=True)
after = open("CLAUDE.md").read()
print(count(after) - count(before))
```

Full docs: see the Token Counting entry in `shared/live-sources.md`.
</doc>

<doc path="shared/tool-use-concepts.md">
# Tool Use Concepts

This file covers the conceptual foundations of tool use with the Claude API. For language-specific code
examples, see the `python/`, `typescript/`, or other language folders. For decision heuristics on which tools
to expose, how to manage context in long-running agents, and caching strategy, see `agent-design.md`.

## User-Defined Tools

### Tool Definition Structure

> **Note:** When using the Tool Runner (beta), tool schemas are generated automatically from your function
signatures (Python), Zod schemas (TypeScript), annotated classes (Java), `jsonschema` struct tags (Go), or
`BaseTool` subclasses (Ruby). The raw JSON schema format below is for the manual approach -- including PHP's
`BetaRunnableTool`, which wraps a run closure around a hand-written schema -- or SDKs without tool runner
support.

Each tool requires a name, description, and JSON Schema for its inputs:

```json
{
  "name": "get_weather",
  "description": "Get current weather for a location",
  "input_schema": {
    "type": "object",
    "properties": {
      "location": {
        "type": "string",
        "description": "City and state, e.g., San Francisco, CA"
      },
      "unit": {
        "type": "string",
        "enum": ["celsius", "fahrenheit"],
        "description": "Temperature unit"
      }
    },
````
````

```
    "required": ["location"]
  }
}
```

Best practices for tool definitions:

- Use clear, descriptive names (e.g., `get_weather`, `search_database`, `send_email`)
- Write detailed descriptions -- Claude uses these to decide when to use the tool. Be **prescriptive about *when* to call it**, not just what it does (e.g. "Call this when the user asks about current prices or recent events"). On recent Opus models, which reach for tools more conservatively, trigger conditions in the description give measurable lift in should-call rate.
- Include descriptions for each property
- Use `enum` for parameters with a fixed set of values
- Mark truly required parameters in `required`; make others optional with defaults

---

Tool Choice Options

Control when Claude uses tools:

Value	Behavior
`{"type": "auto"}`	Claude decides whether to use tools (default)
`{"type": "any"}`	Claude must use at least one tool
`{"type": "tool", "name": "..."}`	Claude must use the specified tool
`{"type": "none"}`	Claude cannot use tools

Any `tool_choice` value can also include `"disable_parallel_tool_use": true` to force Claude to use at most one tool per response. By default, Claude may request multiple tool calls in a single response.

Tool Runner vs Manual Loop

Tool Runner (Recommended): The SDK's tool runner handles the agentic loop automatically -- it calls the API, detects tool use requests, executes your tool functions, feeds results back to Claude, and repeats until Claude stops calling tools. Available in Python, TypeScript, Java, Go, Ruby, PHP, and C# SDKs (beta). The Python SDK also provides MCP conversion helpers (`anthropic.lib.tools.mcp`) to convert MCP tools, prompts, and resources for use with the tool runner -- see `python/claude-api/tool-use.md` for details. **Default to the tool runner** for any custom-tool agent.

The tool runner is not a black box -- "I need control" is rarely a reason to drop to the manual loop. Each iteration yields the assistant message *before* the tools run and lets you intervene, so most "fine-grained control" needs are covered without hand-writing the loop:

- **Human-in-the-loop approval / gating** -- gate in the tool's run function (return a "user declined" result instead of executing), or inspect the tool call in the yielded message and override the pending request with `set_messages_params()` / `setMessagesParams()` / `append_messages()` / `pushMessages()` to allow or deny *before* the tool executes. The runner runs your function automatically only if you don't intervene.
- **Error interception** -- inspect the tool result before it returns to Claude (`generate_tool_call_response()` / `generateToolResponse()`); stop early or handle it yourself.
- **Result modification** -- mutate the tool result before it goes back (e.g. add `cache_control` for prompt caching, or transform the output).
- **Per-turn retries / param changes** -- e.g. bump `max_tokens` and re-run a truncated turn; bound the whole loop with `max_iterations`.
- **Streaming and automatic compaction** are both supported.

These hooks are SDK helper features, not separate API parameters -- for the exact method names and worked examples, WebFetch the per-language SDK repo listed in `shared/live-sources.md` -> *Claude API SDK Repositories* (the tool-runner helpers live in each repo's `tools.md` / `helpers.md`). The bundled `python/claude-api/tool-use.md` and `typescript/claude-api/tool-use.md` show the basic tool-runner setup.

Don't drop to a manual loop because of these misconceptions:

- The tool runner does not require Zod/Pydantic -- `betaTool()` (TS) and `@beta_tool` (Python) accept raw JSON Schema; other SDKs use plain structs/maps/classes.
- The runner makes detecting the final turn *easier*, not harder -- iteration ends when Claude stops calling tools, and the last yielded message is the final response. Most SDKs also offer a one-shot variant

(`runner.until_done()` / `runner.runUntilDone()` / `RunToCompletion()`).
- Confirmation/approval gates work with the runner (see Security below).

Manual Agentic Loop: Reach for this only when you want to own the *entire* loop -- you need control the runner does not expose (e.g., a custom transport, request shapes the SDK cannot build, per-token streaming on SDKs whose runner does not support it), you'd rather not take the beta dependency, or your control flow doesn't fit the runner's per-turn hooks (e.g. interleaving unrelated work mid-loop). Approval gates, logging, interception, result modification, and conditional execution do **not** require it -- the tool runner covers those (above). Loop until `stop_reason == "end_turn"`, always append the full `response.content` to preserve tool_use blocks, and ensure each `tool_result` includes the matching `tool_use_id`.

Stop reasons for server-side tools: When using server-side tools (code execution, web search, etc.), the API runs a server-side sampling loop. If this loop reaches its default limit of 10 iterations, the response will have `stop_reason: "pause_turn"`. To continue, re-send the user message and assistant response and make another API request -- the server will resume where it left off. Do NOT add an extra user message like "Continue." -- the API detects the trailing `server_tool_use` block and knows to resume automatically.

```python
# Handle pause_turn in your agentic loop
if response.stop_reason == "pause_turn":
    messages = [
        {"role": "user", "content": user_query},
        {"role": "assistant", "content": response.content},
    ]
    # Make another API request -- server resumes automatically
    response = client.messages.create(
        model="claude-opus-5", messages=messages, tools=tools
    )
```

Note: the SDK tool runners do not auto-resume `pause_turn` (as of `@anthropic-ai/sdk` 0.110.0 / `anthropic` 0.116.0) -- a paused turn ends the runner and is returned as the final message, with no error. In TypeScript you can resume inside the iteration body (push the paused assistant turn back onto the runner); in Python the runner cannot be resumed mid-loop -- restart a new runner with the paused turn appended, or handle `pause_turn` in a manual loop. See each language's `tool-use.md` for the pattern.

Set a `max_continuations` limit (e.g., 5) to prevent infinite loops. For the full guide, see:
`https://platform.claude.com/docs/en/build-with-claude/handling-stop-reasons`

> **Security:** The tool runner executes your tool functions automatically whenever Claude requests them. For tools with side effects (sending emails, modifying databases, financial transactions), validate inputs and gate destructive operations behind human approval. **Both** the tool runner and the manual loop support this -- with the tool runner, gate inside the tool's run function (prompt the user and return a "user declined" result instead of executing), or inspect the tool call in each yielded message and take over message history with `set_messages_params()` / `setMessagesParams()` to allow or deny *before* the tool runs (it executes your function automatically only if you don't intervene); with the manual loop you gate inline before calling the function.

Handling Tool Results

When Claude uses a tool, the response contains a `tool_use` block. You must:

1. Execute the tool with the provided input
2. Send the result back in a `tool_result` message
3. Continue the conversation

Error handling in tool results: When a tool execution fails, set `"is_error": true` and provide an informative error message. Claude will typically acknowledge the error and either try a different approach or ask for clarification.

Multiple tool calls: Claude can request multiple tools in a single response. Handle them all before continuing -- send all results back in a single `user` message.

Server-Side Tools: Code Execution

The code execution tool lets Claude run code in a secure, sandboxed container. Unlike user-defined tools,

server-side tools run on Anthropic's infrastructure -- you don't execute anything client-side. Just include the tool definition and Claude handles the rest.

Key Facts

- Runs in an isolated container (1 CPU, 5 GiB RAM, 5 GiB disk)
- No internet access (fully sandboxed)
- Python 3.11 with data science libraries pre-installed
- Containers persist for 30 days and can be reused across requests
- Free when used with web search/web fetch tools; otherwise $0.05/hour after 1,550 free hours/month per organization

Tool Definition

The tool requires no schema -- just declare it in the `tools` array:

```json
{
  "type": "code_execution_20260120",
  "name": "code_execution"
}
```

Claude automatically gains access to `bash_code_execution` (run shell commands) and `text_editor_code_execution` (create/view/edit files).

Pre-installed Python Libraries

- **Data science**: pandas, numpy, scipy, scikit-learn, statsmodels
- **Visualization**: matplotlib, seaborn
- **File processing**: openpyxl, xlsxwriter, pillow, pypdf, pdfplumber, python-docx, python-pptx
- **Math**: sympy, mpmath
- **Utilities**: tqdm, python-dateutil, pytz, sqlite3

Additional packages can be installed at runtime via `pip install`.

Supported File Types for Upload

Type	Extensions
Data	CSV, Excel (.xlsx/.xls), JSON, XML
Images	JPEG, PNG, GIF, WebP
Text	.txt, .md, .py, .js, etc.

Container Reuse

Reuse containers across requests to maintain state (files, installed packages, variables). Extract the `container_id` from the first response and pass it to subsequent requests.

Response Structure

The response contains interleaved text and tool result blocks:

- `text` -- Claude's explanation
- `server_tool_use` -- What Claude is doing
- `bash_code_execution_tool_result` -- Code execution output (check `return_code` for success/failure)
- `text_editor_code_execution_tool_result` -- File operation results

> **Security:** Always sanitize filenames with `os.path.basename()` / `path.basename()` before writing downloaded files to disk to prevent path traversal attacks. Write files to a dedicated output directory.

Server-Side Tools: Web Search and Web Fetch

Web search and web fetch let Claude search the web and retrieve page content. They run server-side -- just include the tool definitions and Claude handles queries, fetching, and result processing automatically.

Tool Definitions

```json
[
  { "type": "web_search_20260209", "name": "web_search" },
  { "type": "web_fetch_20260209", "name": "web_fetch" }
]
```

Dynamic Filtering (Claude Opus 5 / Fable 5 / Opus 4.8 / Opus 4.7 / Opus 4.6 / Sonnet 5 / Sonnet 4.6)

The `web_search_20260209` and `web_fetch_20260209` versions support **dynamic filtering** -- Claude writes and executes code to filter search results before they reach the context window, improving accuracy and token efficiency. Dynamic filtering is built into these tool versions and activates automatically; you do not need to separately declare the `code_execution` tool or pass any beta header.

```json
{
  "tools": [
    { "type": "web_search_20260209", "name": "web_search" },
    { "type": "web_fetch_20260209", "name": "web_fetch" }
  ]
}
```

Without dynamic filtering, the previous `web_search_20250305` version is also available.

> **Note:** Only include the standalone `code_execution` tool when your application needs code execution for its own purposes (data analysis, file processing, visualization) independent of web search. Including it alongside `_20260209` web tools creates a second execution environment that can confuse the model.

Server-Side Tools: Programmatic Tool Calling

With standard tool use, each tool call is a round trip: Claude calls, the result enters Claude's context, Claude reasons, then calls the next tool. Chained calls accumulate latency and tokens -- most of that intermediate data is never needed again.

Programmatic tool calling lets Claude compose those calls into a script. The script runs in the code execution container; when it invokes a tool, the container pauses, the call executes, and the result returns to the running code (not to Claude's context). The script processes it with normal control flow. Only the final output returns to Claude. Use it when chaining many tool calls or when intermediate results are large and should be filtered before reaching the context window.

For full documentation, use WebFetch:

- URL: `https://platform.claude.com/docs/en/agents-and-tools/tool-use/programmatic-tool-calling`

Server-Side Tools: Tool Search

The tool search tool lets Claude dynamically discover tools from large libraries without loading all definitions into the context window. Use it when you have many tools but only a few are relevant to any given request. Discovered tool schemas are appended to the request, not swapped in -- this preserves the prompt cache (see `agent-design.md` ?Caching for Agents).

For full documentation, use WebFetch:

- URL: `https://platform.claude.com/docs/en/agents-and-tools/tool-use/tool-search-tool`

Mid-conversation tool changes (Beta)

Beta header `mid-conversation-tool-changes-2026-07-01`; Claude Opus 5 onward. Normally `tools` is fixed for a conversation's lifetime -- editing it changes the very front of the prompt prefix and invalidates the entire cache (see `prompt-caching.md` ? Invalidation hierarchy). This feature lets you add and remove tools between turns while the cached prefix survives.

Both operations are content blocks on a `{"role": "system", ...}` message appended to `messages[]`, and both

reference a tool by name via a `tool_reference`:

```python
# Removal -- must sit immediately before an assistant message, or last in messages.
{"role": "system", "content": [
    {"type": "tool_removal", "tool": {"type": "tool_reference", "name": "get_weather"}},
]}

# Addition -- surfaces a tool declared up front with defer_loading.
{"role": "system", "content": [
    {"type": "tool_addition", "tool": {"type": "tool_reference", "name": "get_forecast"}},
]}
```

A tool you plan to add must already be declared in `tools[]` with `"defer_loading": True`. Deferred tools are known to the request but not loaded into the model's context until a `tool_addition` surfaces them:

```python
tools = [
    {"name": "get_weather", "description": "Get weather",
     "input_schema": {"type": "object", "properties": {"city": {"type": "string"}}}},
    {"name": "get_forecast", "description": "Get 5-day forecast",
     "input_schema": {"type": "object", "properties": {"city": {"type": "string"}}},
     "defer_loading": True},
]
```

To change a tool's definition, do it across two requests: send a `tool_removal` for the old definition on the first, then carry the conversation forward with the updated entry in `tools[]` on the next.

> ?? Earlier previews used a different beta header and different block shapes; both are deprecated. Use `mid-conversation-tool-changes-2026-07-01` with `tool_addition` / `tool_removal` / `tool_reference`.

SDK typings lag these blocks -- pass them as plain dicts in Python, or add a `@ts-expect-error` in TypeScript.

Choosing between this and tool search: tool search is for *discovery* -- Claude finds what it needs from a large library on its own. Mid-conversation tool changes are for *control* -- your application decides the tool set has changed (a mode switch, a resource that became available, a capability you want to revoke) and says so explicitly.

Agent Skills (Messages API)

Agent Skills package task-specific instructions and files that Claude loads when relevant (e.g., the Anthropic pre-built `pptx`, `xlsx`, `pdf`, `docx` skills). On the **Messages API**, skills are enabled via the `container` parameter alongside the code-execution tool -- this is **not** the Managed Agents surface and does **not** use `client.beta.agents` / `sessions` / `environments`. Availability: see `shared/platform-availability.md`.

Required on each request:

1. `client.beta.messages.create(...)` with **both** beta flags: `code-execution-2025-08-25` **and** `skills-2025-10-02`.
2. `container={"skills": [{"type": "anthropic", "skill_id": "<id>", "version": "latest"}]}` -- the skills list selects which skills are available inside the execution container.
3. `tools=[{"type": "code_execution_20260521", "name": "code_execution"}]` -- skills execute via code execution in the container.

```python
response = client.beta.messages.create(
    model="claude-opus-5", max_tokens=16000,
    betas=["code-execution-2025-08-25", "skills-2025-10-02"],
    container={"skills": [{"type": "anthropic", "skill_id": "pptx", "version": "latest"}]},
    tools=[{"type": "code_execution_20260521", "name": "code_execution"}],
    messages=[{"role": "user", "content": "Create a 3-slide presentation on X"}],
)
```

Generated files (`.pptx`, `.xlsx`, ...) are written inside the container; the response carries a file ID for

````
each. Download by passing that ID to the Files API (`client.beta.files.download(file_id)` / `GET
/v1/files/{id}/content` with `anthropic-beta: files-api-2025-04-14`).

List available skills via `GET /v1/skills` (requires `anthropic-beta: skills-2025-10-02`).

---

## MCP Connector (Beta)

The MCP connector lets Claude call tools hosted on a remote MCP server directly from the Messages API --
Anthropic makes the MCP connection server-side. Requires beta flag `mcp-client-2025-11-20` on
`client.beta.messages.create(...)`. Availability: see `shared/platform-availability.md`.

**Two parameters are required together:**

- `mcp_servers` -- array of server connection definitions: `[{"type": "url", "url": "<server URL>", "name":
"<server-name>", "authorization_token": "<optional>"}]`
- `tools` -- must include an `mcp_toolset` entry that references the server by name: `[{"type":
"mcp_toolset", "mcp_server_name": "<server-name>"}]`

The `mcp_server_name` in the toolset must match a `name` in `mcp_servers`. Omitting the `mcp_toolset` entry
is rejected as a validation error -- every server in `mcp_servers` must be referenced by exactly one toolset.

```python
client.beta.messages.create(
    model="claude-opus-5", max_tokens=1024,
    betas=["mcp-client-2025-11-20"],
    mcp_servers=[{"type": "url", "url": "https://example/sse", "name": "example-mcp"}],
    tools=[{"type": "mcp_toolset", "mcp_server_name": "example-mcp"}],
    messages=[...],
)
```

Go uses the typed constant `anthropic.AnthropicBetaMCPClient2025_11_20`; the older `...2025_04_04` constant
is deprecated.

Optional toolset fields: `default_config` (defaults for all tools, e.g. `{"enabled": false}` for allowlist
mode) and `configs` (per-tool overrides keyed by tool name).

---

## Tool Use Examples

You can provide sample tool calls directly in your tool definitions to demonstrate usage patterns and reduce
parameter errors. This helps Claude understand how to correctly format tool inputs, especially for tools with
complex schemas.

For full documentation, use WebFetch:

- URL: `https://platform.claude.com/docs/en/agents-and-tools/tool-use/implement-tool-use`

---

## Client-Side Tools: Computer Use

Computer use lets Claude interact with a desktop environment (screenshots, mouse, keyboard). It is a
client-side tool -- your application provides the environment and executes the actions Claude requests;
Anthropic processes the screenshots and action requests in real time but does not host the environment or
retain the data.

For full documentation, use WebFetch:

- URL: `https://platform.claude.com/docs/en/agents-and-tools/computer-use/overview`

---

## Context Editing

Context editing clears stale tool results and thinking blocks from the transcript as a long-running agent
accumulates turns. Unlike compaction (which summarizes), context editing prunes -- the cleared content is
````

removed, not replaced. Use it when old tool outputs are no longer relevant and you want to keep the transcript lean without losing the conversation structure.

Beta. Use `client.beta.messages.*` with beta `context-management-2025-06-27`. Configure via `context_management.edits` with a strategy type of `clear_tool_uses_20250919` (clear old tool results; optional `clear_tool_inputs: true` also clears the tool_use params) or `clear_thinking_20251015` (clear thinking blocks). These are **not** the compaction types -- `compact_20260112` with beta `compact-2026-01-12` is the separate compaction feature.

For full documentation, use WebFetch:

- URL: `https://platform.claude.com/docs/en/build-with-claude/context-editing`

Server-Side Tools: Advisor (Beta)

The advisor tool pairs a faster, lower-cost **executor** model (the top-level `model` on the request) with a higher-intelligence **advisor** model (the `model` field inside the tool definition) that provides strategic guidance mid-generation. The executor does most of the token generation; the advisor is consulted for planning. Availability: see `shared/platform-availability.md`.

Tool Definition

```json
{
  "type": "advisor_20260301",
  "name": "advisor",
  "model": "claude-opus-4-8"
}
```

Optional fields on the tool definition:

- `max_uses` -- cap on advisor consultations per request. Exceeding it makes the `advisor_tool_result` block's `content` the error object `{"type": "advisor_tool_result_error", "error_code": "max_uses_exceeded"}` -- the third member of the content union in the payload-shape table below.
- `max_tokens` -- bounds the advisor's total output (thinking + text) per call. At the cap the result block carries `stop_reason: "max_tokens"` and a truncation note is appended to the advice the executor sees; the server also emits a remaining-tokens budget block in the advisor's prompt so it self-shapes toward the cap.
- `caching` -- cache-control for the advisor's own prompt, same shape as a cache breakpoint: `"caching": {"type": "ephemeral", "ttl": "5m"}` (`ttl` is `"5m"` or `"1h"`, default `"5m"`). Each call writes a cache entry at that TTL so later calls in the conversation read the stable prefix. Omitted = advisor prompt not cached.

The advisor model must be at least as capable as the executor. An invalid pairing returns `400 invalid_request_error`. Valid pairs:

Executor (request `model`)	Valid advisor (tool `model`)
`claude-haiku-4-5` / `claude-sonnet-4-6` / `claude-sonnet-5` / `claude-opus-4-6` / `claude-opus-4-7`	`claude-opus-5`, `claude-fable-5`, `claude-mythos-5`, `claude-opus-4-8`, or `claude-opus-4-7`
`claude-opus-4-8`	`claude-opus-5`, `claude-fable-5`, `claude-mythos-5`, or `claude-opus-4-8`
`claude-opus-5`	`claude-opus-5`, `claude-fable-5`, or `claude-mythos-5`
`claude-fable-5`	`claude-fable-5` or `claude-opus-5`
`claude-mythos-5`	`claude-mythos-5` or `claude-opus-5`

> ?? **The advisor's payload shape differs by advisor model.** The response block is always `advisor_tool_result`; what varies is its **`content`**, a discriminated union:
>
> | `content` type | Fields | When |
> |---|---|---|
> | `advisor_result` | `text`, `stop_reason` | Advisor returns plaintext (e.g. Opus 4.8) |
> | `advisor_redacted_result` | `encrypted_content`, `stop_reason` | Advisor returns encrypted output -- Claude Opus 5, Claude Fable 5, Claude Mythos 5 |
> | `advisor_tool_result_error` | `error_code` | Consultation failed -- `max_uses_exceeded`, `prompt_too_long`, `too_many_requests`, `overloaded`, `unavailable`, `execution_time_exceeded`, or `model_not_found` |
>
> So switch on `advisor_tool_result.content` type, not on the block type. Code that reads `.text`

unconditionally gets nothing back from an Claude Opus 5 advisor, because the payload is under `encrypted_content` instead -- and you cannot read it, only replay it.

Call via `client.beta.messages.create(...)` with `betas=["advisor-tool-2026-03-01"]` (or the `anthropic-beta: advisor-tool-2026-03-01` header). In multi-turn conversations, append the full `response.content` -- including any `advisor_tool_result` blocks -- back to `messages` on the next turn. If you remove the advisor tool from `tools` on a later turn while the history still contains `advisor_tool_result` blocks, the API returns a 400.

> **Advisor on Managed Agents:** CMA sessions support an advisor too, configured as a `{"type": "advisor", "model"}` entry in the agent's multiagent roster rather than as a tool definition -- no `max_uses`/`max_tokens`/`caching` options, and advice is delivered as thread events on the session's event stream rather than `advisor_tool_result` blocks. See `shared/managed-agents-multiagent.md` -> Advisor.

Client-Side Tools: Memory

The memory tool enables Claude to store and retrieve information across conversations through a memory file directory. Claude can create, read, update, and delete files that persist between sessions.

Key Facts

- Client-side tool -- you control storage via your implementation
- Supports commands: `view`, `create`, `str_replace`, `insert`, `delete`, `rename`
- Operates on files in a `/memories` directory
- The Python, TypeScript, and Java SDKs provide helper classes/functions for implementing the memory backend

> **Security:** Never store API keys, passwords, tokens, or other secrets in memory files. Be cautious with personally identifiable information (PII) -- check data privacy regulations (GDPR, CCPA) before persisting user data. The reference implementations have no built-in access control; in multi-user systems, implement per-user memory directories and authentication in your tool handlers.

For full implementation examples, use WebFetch:

- Docs: `https://platform.claude.com/docs/en/agents-and-tools/tool-use/memory-tool.md`

Client-Side Tools: Bash and Text Editor

The bash and text editor tools are **Anthropic-defined, schema-less** tools. Declare them by `type` and `name` only -- the input schema is built into the model and cannot be modified. **Do not pass an `input_schema`**, and do not define a custom tool that happens to be named `"bash"` -- that creates a user-defined tool without the built-in behavior.

Both are **client-executed**: Claude returns a `tool_use` block, your code performs the action locally, and you send back a `tool_result`. The API is stateless; your application maintains the shell session or filesystem between turns.

Bash tool declaration

```json
{"type": "bash_20250124", "name": "bash"}
```

Language	Declaration
Python / TypeScript / Ruby / cURL	plain object `{"type": "bash_20250124", "name": "bash"}`
Go	`anthropic.ToolUnionParam{OfBashTool20250124: &anthropic.ToolBash20250124Param{}}`
Java	`.addTool(ToolBash20250124.builder().build())` from `com.anthropic.models.messages`
C#	`Tools = [new ToolBash20250124()]` from `Anthropic.Models.Messages`
PHP	`tools: [new \Anthropic\Messages\ToolBash20250124()]`

Claude's `tool_use.input` contains either `{"command": "<string>"}` or `{"restart": true}`. Check for `restart` first (reset the session, return a confirmation string); otherwise run `command` and return combined stdout + stderr.

> **Security -- commands are untrusted model output.** Run in an isolated environment (container, VM, or restricted user); apply an **allowlist** of permitted executables and reject shell operators (`&&`, `|`, `;`,

`` ` ``, `$()`); set timeouts and resource limits; log every command. A blocklist is not sufficient.

Text editor tool declaration

```json
{"type": "text_editor_20250728", "name": "str_replace_based_edit_tool"}
```

Optional field: `max_characters` to cap `view` output. Java exposes a typed `ToolTextEditor20250728` builder (`com.anthropic.models.messages`); other statically-typed SDKs follow the same naming pattern -- see the Anthropic-Defined Tools section in `{lang}/claude-api/tool-use.md` for the exact class.

> **Security -- `path` is untrusted model output. Confine every file operation to a fixed project root.** Before executing any command, resolve the model-supplied `path` to its canonical form and verify it remains within your project root; reject the request if it escapes (`..`, symlinks, absolute paths outside the root, URL-encoded traversal like `%2e%2e%2f`). Use your language's built-in path utilities (e.g., Python `pathlib.Path.resolve()` then check `.is_relative_to(root)`). Never call `open()` / `writeFile` / `unlink` directly on the raw `path` value.

`tool_use.input.command` is one of:

`command`	Other inputs	Action
`view`	`path`, optional `view_range`	Return file contents or directory listing
`create`	`path`, `file_text`	Create/overwrite file with `file_text`. Create a backup if the file already exists.
`str_replace`	`path`, `old_str`, `new_str`	Replace exactly one occurrence; error if 0 or >1 matches
`insert`	`path`, `insert_line`, `insert_text`	Insert `insert_text` after line `insert_line` (0 = beginning of file)

For both tools, on error return `{"type": "tool_result", "tool_use_id": "...", "content": "<error text>", "is_error": true}` so Claude can recover.

Structured Outputs

Structured outputs constrain Claude's responses to follow a specific JSON schema, guaranteeing valid, parseable output. This is not a separate tool -- it enhances the Messages API response format and/or tool parameter validation.

Two features are available:

- **JSON outputs** (`output_config.format`): Control Claude's response format
- **Strict tool use** (`strict: true`): Guarantee valid tool parameter schemas

Supported models: Claude Fable 5, Claude Opus 5, Claude Opus 4.8, Claude Sonnet 5, and Claude Haiku 4.5. Legacy models (Claude Opus 4.5, Claude Opus 4.1) also support structured outputs.

> **Recommended:** Use `client.messages.parse()` which automatically validates responses against your schema. When using `messages.create()` directly, use `output_config: {format: {...}}`. The `output_format` convenience parameter is also accepted by some SDK methods (e.g., `.parse()`), but `output_config.format` is the canonical API-level parameter.

JSON Schema Limitations

Supported:

- Basic types: object, array, string, integer, number, boolean, null
- `enum`, `const`, `anyOf`, `allOf`, `$ref`/`$def`
- String formats: `date-time`, `time`, `date`, `duration`, `email`, `hostname`, `uri`, `ipv4`, `ipv6`, `uuid`
- `additionalProperties: false` (required for all objects)

Not supported:

- Recursive schemas
- Numerical constraints (`minimum`, `maximum`, `multipleOf`)
- String constraints (`minLength`, `maxLength`)
- Complex array constraints
- `additionalProperties` set to anything other than `false`

````
The Python and TypeScript SDKs automatically handle unsupported constraints by removing them from the schema
sent to the API and validating them client-side.

### Important Notes

- **First request latency**: New schemas incur a one-time compilation cost. Subsequent requests with the same
schema use a 24-hour cache.
- **Refusals**: If Claude refuses for safety reasons (`stop_reason: "refusal"`), the output may not match
your schema.
- **Token limits**: If `stop_reason: "max_tokens"`, output may be incomplete. Increase `max_tokens`.
- **Incompatible with**: Citations (returns 400 error), message prefilling.
- **Works with**: Batches API, streaming, token counting, extended thinking.

---

## Tips for Effective Tool Use

1. **Provide detailed descriptions**: Claude relies heavily on descriptions to understand when and how to use
tools
2. **Use specific tool names**: `get_current_weather` is better than `weather`
3. **Validate inputs**: Always validate tool inputs before execution
4. **Handle errors gracefully**: Return informative error messages so Claude can adapt
5. **Limit tool count**: Too many tools can confuse the model -- keep the set focused
6. **Test tool interactions**: Verify Claude uses tools correctly in various scenarios

For detailed tool use documentation, use WebFetch:

- URL: `https://platform.claude.com/docs/en/agents-and-tools/tool-use/overview`
</doc>

<doc path="typescript/claude-api/README.md">
# Claude API -- TypeScript

| Feature | Namespace | Key types / call |
|---|---|---|
| User profiles | beta | `client.beta.userProfiles.create(...)` / `.retrieve(id)` / `.list()`. Pass the
returned profile id on `client.beta.messages.create`. Requires a beta header -- check the SDK's beta-headers
reference for the current flag. |

## Installation

```bash
npm install @anthropic-ai/sdk
```

> **Reading local files (ESM):** `__dirname` and `__filename` are **undefined** in ES modules -- using either
throws `ReferenceError: __dirname is not defined` at runtime. For cwd-relative reads, pass the bare relative
path (`fs.readFileSync("./sample.png")`). For script-relative paths, derive the directory from
`import.meta.url`: `const here = path.dirname(fileURLToPath(import.meta.url))`. Never write
`path.join(__dirname, ...)` in an ESM `.ts` file.

## Client Initialization

```typescript
import Anthropic from "@anthropic-ai/sdk";

// Default -- resolves credentials from the environment:
// ANTHROPIC_API_KEY, or ANTHROPIC_AUTH_TOKEN, or an `ant auth login` profile.
// Prefer this for local dev; don't hardcode a key.
const client = new Anthropic();

// Explicit API key (only when you must inject a specific key)
const client = new Anthropic({ apiKey: "your-api-key" });
```

---

## Basic Message Request
````

```typescript
const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  messages: [{ role: "user", content: "What is the capital of France?" }],
});
// response.content is ContentBlock[] -- a discriminated union. Narrow by .type
// before accessing .text (TypeScript will error on content[0].text without this).
for (const block of response.content) {
  if (block.type === "text") {
    console.log(block.text);
  }
}
```

System Prompts

```typescript
const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  system:
    "You are a helpful coding assistant. Always provide examples in Python.",
  messages: [{ role: "user", content: "How do I read a JSON file?" }],
});
```

Mid-conversation system messages (model-gated)

For operator instructions that arrive mid-conversation (mode switches, injected state), append `{role: "system", ...}` to `messages` instead of editing top-level `system` -- this preserves the cached prefix and carries operator authority. Must follow a user message (or an `assistant` message ending in server-tool use), and must be either the last entry in `messages` or be followed by an `assistant` turn; cannot be `messages[0]`. Unsupported models return a 400 (`role 'system' is not supported on this model`). See `shared/prompt-caching.md` for when to use this vs. top-level `system`.

```typescript
// No beta header needed -- use regular client.messages.create.
const response = await client.messages.create({
  model: MODEL_ID, // must support mid-conversation system messages
  max_tokens: 16000,
  system: [
    { type: "text", text: STABLE_SYSTEM, cache_control: { type: "ephemeral" } },
  ],
  messages: [
    ...history,
    { role: "user", content: userMessage },
    { role: "system", content: "Terse mode enabled -- keep responses under 40 words." },
  ],
});
```

Vision (Images)

URL

```typescript
const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  messages: [
    {
      role: "user",
      content: [
        {
          type: "image",
```

```
          source: { type: "url", url: "https://example.com/image.png" },
        },
        { type: "text", text: "Describe this image" },
      ],
    },
  ],
});
```

Base64

```typescript
import fs from "fs";

const imageData = fs.readFileSync("image.png").toString("base64");

const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  messages: [
    {
      role: "user",
      content: [
        {
          type: "image",
          source: { type: "base64", media_type: "image/png", data: imageData },
        },
        { type: "text", text: "What's in this image?" },
      ],
    },
  ],
});
```

Prompt Caching

Caching is a prefix match -- any byte change anywhere in the prefix invalidates everything after it. For placement patterns, architectural guidance (frozen system prompt, deterministic tool order, where to put volatile content), and the silent-invalidator audit checklist, read `shared/prompt-caching.md`.

Automatic Caching (Recommended)

Use top-level `cache_control` to automatically cache the last cacheable block in the request:

```typescript
const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  cache_control: { type: "ephemeral" }, // auto-caches the last cacheable block
  system: "You are an expert on this large document...",
  messages: [{ role: "user", content: "Summarize the key points" }],
});
```

Manual Cache Control

For fine-grained control, add `cache_control` to specific content blocks:

```typescript
const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  system: [
    {
      type: "text",
      text: "You are an expert on this large document...",
      cache_control: { type: "ephemeral" }, // default TTL is 5 minutes
    },
```

```
  ],
  messages: [{ role: "user", content: "Summarize the key points" }],
});

// With explicit TTL (time-to-live)
const response2 = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  system: [
    {
      type: "text",
      text: "You are an expert on this large document...",
      cache_control: { type: "ephemeral", ttl: "1h" }, // 1 hour TTL
    },
  ],
  messages: [{ role: "user", content: "Summarize the key points" }],
});
```

Verifying Cache Hits

```typescript
console.log(response.usage.cache_creation_input_tokens); // tokens written to cache (~1.25x cost)
console.log(response.usage.cache_read_input_tokens);     // tokens served from cache (~0.1x cost)
console.log(response.usage.input_tokens);                // uncached tokens (full cost)
```

If `cache_read_input_tokens` is zero across repeated identical-prefix requests, a silent invalidator is at work -- `Date.now()` or a UUID in the system prompt, non-deterministic key ordering, or a varying tool set. See `shared/prompt-caching.md` for the full audit table.

Extended Thinking

> **Fable 5, Claude Opus 5, Opus 4.8, Opus 4.7, Opus 4.6, and Sonnet 4.6:** Use adaptive thinking. `budget_tokens` is removed on Fable 5, Claude Opus 5, Opus 4.8, and 4.7 (400 if sent); deprecated on Opus 4.6 and Sonnet 4.6.
> **Claude Opus 5:** thinking is on by default -- omitting `thinking` runs adaptive (`{ type: "adaptive" }` is equivalent), unlike Opus 4.8/4.7 where omitting it meant no thinking. `{ type: "disabled" }` is accepted only at effort `high` or lower; pairing it with `xhigh`/`max` returns a 400.
> **Older models:** Use `thinking: {type: "enabled", budget_tokens: N}` (must be < `max_tokens`, min 1024).

```typescript
// Fable 5 / Claude Opus 5 / Opus 4.8 / 4.7 / 4.6: adaptive thinking (recommended)
const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  thinking: { type: "adaptive", display: "summarized" }, // display opt-in: default is omitted (empty thinking text) on Fable 5 / Mythos 5 / Claude Opus 5 / Opus 4.8 / 4.7
  output_config: { effort: "high" }, // low | medium | high | xhigh | max
  messages: [
    { role: "user", content: "Solve this math problem step by step..." },
  ],
});

for (const block of response.content) {
  if (block.type === "thinking") {
    console.log("Thinking:", block.thinking);
  } else if (block.type === "text") {
    console.log("Response:", block.text);
  }
}
```

Error Handling

Use the SDK's typed exception classes -- never check error messages with string matching:

```typescript
import Anthropic from "@anthropic-ai/sdk";

try {
  const response = await client.messages.create({...});
} catch (error) {
  if (error instanceof Anthropic.BadRequestError) {
    console.error("Bad request:", error.message);
  } else if (error instanceof Anthropic.AuthenticationError) {
    console.error("Invalid API key");
  } else if (error instanceof Anthropic.RateLimitError) {
    console.error("Rate limited - retry later");
  } else if (error instanceof Anthropic.APIError) {
    console.error(`API error ${error.status}:`, error.message);
  }
}
```

All classes extend `Anthropic.APIError` with a typed `status` field. Check from most specific to least specific. See [shared/error-codes.md](../../shared/error-codes.md) for the full error code reference.

Multi-Turn Conversations

The API is stateless -- send the full conversation history each time. Use `Anthropic.MessageParam[]` to type the messages array:

```typescript
const messages: Anthropic.MessageParam[] = [
  { role: "user", content: "My name is Alice." },
  { role: "assistant", content: "Hello Alice! Nice to meet you." },
  { role: "user", content: "What's my name?" },
];

const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  messages: messages,
});
```

Rules:

- Consecutive same-role messages are allowed -- the API combines them into a single turn
- First message must be `user`
- Use SDK types (`Anthropic.MessageParam`, `Anthropic.Message`, `Anthropic.Tool`, etc.) for all API data structures -- don't redefine equivalent interfaces

---

Compaction (long conversations)

> **Beta, Fable 5, Claude Opus 5, Opus 4.8, Opus 4.7, Opus 4.6, and Sonnet 4.6.** When conversations approach the 200K context window, compaction automatically summarizes earlier context server-side. The API returns a `compaction` block; you must pass it back on subsequent requests -- append `response.content`, not just the text.

```typescript
import Anthropic from "@anthropic-ai/sdk";

const client = new Anthropic();
const messages: Anthropic.Beta.BetaMessageParam[] = [];

async function chat(userMessage: string): Promise<string> {
  messages.push({ role: "user", content: userMessage });

  const response = await client.beta.messages.create({
    betas: ["compact-2026-01-12"],
```

```
    model: "claude-opus-5",
    max_tokens: 16000,
    messages,
    context_management: {
      edits: [{ type: "compact_20260112" }],
    },
  });

  // Append full content -- compaction blocks must be preserved
  messages.push({ role: "assistant", content: response.content });

  const textBlock = response.content.find(
    (b): b is Anthropic.Beta.BetaTextBlock => b.type === "text",
  );
  return textBlock?.text ?? "";
}

// Compaction triggers automatically when context grows large
console.log(await chat("Help me build a Python web scraper"));
console.log(await chat("Add support for JavaScript-rendered pages"));
console.log(await chat("Now add rate limiting and error handling"));
```

Stop Reasons

The `stop_reason` field in the response indicates why the model stopped generating:

Value	Meaning
`end_turn`	Claude finished its response naturally
`max_tokens`	Hit the `max_tokens` limit -- increase it or use streaming
`stop_sequence`	Hit a custom stop sequence
`tool_use`	Claude wants to call a tool -- execute it and continue
`pause_turn`	Model paused and can be resumed (agentic flows)
`refusal`	Claude refused for safety reasons -- check `stop_details`

Structured Stop Details

When `stop_reason` is `"refusal"`, the response includes a `stop_details` object with structured information about the refusal:

```typescript
if (response.stop_reason === "refusal" && response.stop_details) {
  console.log(`Category: ${response.stop_details.category}`); // e.g. "cyber", "bio", "reasoning_extraction",
"frontier_llm", or null -- see docs for the full set
  console.log(`Explanation: ${response.stop_details.explanation}`);
}
```

Refusal Fallbacks (Claude Fable 5) -- opt in by default

Fallbacks are **opt-in**: without them a refused request simply stops. Include the server-side `fallbacks` parameter in `claude-fable-5` code by default -- on a policy decline the API re-runs the same request on the fallback model inside the same call. A decline before any output isn't billed (a mid-stream decline bills the streamed partial); the rescue bills at the fallback model's own rates, with cache repricing applied automatically.

```typescript
const response = await client.beta.messages.create({
  model: "claude-fable-5",
  max_tokens: 16000,
  betas: ["server-side-fallback-2026-06-01"],
  fallbacks: [{ model: "claude-opus-4-8" }],
  messages: [{ role: "user", content: "..." }],
});

// Switch points: one fallback block per model that ran and declined this turn
for (const block of response.content) {
```

```
  if (block.type === "fallback") {
    console.log(`${block.from.model} declined; ${block.to.model} continued`);
  }
}

// Served-by signal -- covers sticky turns, which carry no fallback block.
// Pair with stop_reason: the fallback model can itself refuse.
const fallbackRan = (response.usage.iterations ?? []).some(
  (entry) => entry.type === "fallback_message",
);
if (fallbackRan && response.stop_reason !== "refusal") {
  console.log(`Served by ${response.model}`);
}
```

A `stop_reason: "refusal"` on the final response means the whole chain refused. The header must be exactly `server-side-fallback-2026-06-01` **for this array form**; the newer `fallbacks: "default"` scalar form uses `server-side-fallback-2026-07-01` instead (see `shared/model-migration.md` -> Migrating to Claude Opus 5 -> New API features), and pairing either header with the other form returns a 400. The parameter is rejected on the Batches API and unavailable on Amazon Bedrock, Vertex AI, and Microsoft Foundry -- register the client-side `betaRefusalFallbackMiddleware` on the client there instead. Full semantics (sticky routing, billing, streaming, echoing fallback turns back): `shared/model-migration.md` -> Migrating to Claude Fable 5 -> `refusal` stop reason.

Cost Optimization Strategies

1. Use Prompt Caching for Repeated Context

```typescript
// Automatic caching (simplest -- caches the last cacheable block)
const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  cache_control: { type: "ephemeral" },
  system: largeDocumentText, // e.g., 50KB of context
  messages: [{ role: "user", content: "Summarize the key points" }],
});

// First request: full cost
// Subsequent requests: ~90% cheaper for cached portion
```

2. Use Token Counting Before Requests

```typescript
const countResponse = await client.messages.countTokens({
  model: "claude-opus-5",
  messages: messages,
  system: system,
});

const estimatedInputCost = countResponse.input_tokens * 0.000005; // $5/1M tokens
console.log(`Estimated input cost: $${estimatedInputCost.toFixed(4)}`);
```
</doc>

<doc path="typescript/claude-api/batches.md">
Message Batches API -- TypeScript

The Batches API (`POST /v1/messages/batches`) processes Messages API requests asynchronously at 50% of standard prices.

Key Facts

- Up to 100,000 requests or 256 MB per batch
- Most batches complete within 1 hour; maximum 24 hours
- Results available for 29 days after creation
- 50% cost reduction on all token usage

```
- All Messages API features supported (vision, tools, caching, etc.)

---

## Create a Batch

```typescript
import Anthropic from "@anthropic-ai/sdk";

const client = new Anthropic();

const messageBatch = await client.messages.batches.create({
  requests: [
    {
      custom_id: "request-1",
      params: {
        model: "claude-opus-5",
        max_tokens: 16000,
        messages: [
          { role: "user", content: "Summarize climate change impacts" },
        ],
      },
    },
    {
      custom_id: "request-2",
      params: {
        model: "claude-opus-5",
        max_tokens: 16000,
        messages: [
          { role: "user", content: "Explain quantum computing basics" },
        ],
      },
    },
  ],
});

console.log(`Batch ID: ${messageBatch.id}`);
console.log(`Status: ${messageBatch.processing_status}`);
```

Poll for Completion

```typescript
let batch;
while (true) {
  batch = await client.messages.batches.retrieve(messageBatch.id);
  if (batch.processing_status === "ended") break;
  console.log(
    `Status: ${batch.processing_status}, processing: ${batch.request_counts.processing}`,
  );
  await new Promise((resolve) => setTimeout(resolve, 60_000));
}

console.log("Batch complete!");
console.log(`Succeeded: ${batch.request_counts.succeeded}`);
console.log(`Errored: ${batch.request_counts.errored}`);
```

Retrieve Results

```typescript
for await (const result of await client.messages.batches.results(
  messageBatch.id,
)) {
  switch (result.result.type) {
    case "succeeded":
```
```

```
      console.log(
        `[${result.custom_id}] ${result.result.message.content[0].text.slice(0, 100)}`,
      );
      break;
    case "errored":
      if (result.result.error.type === "invalid_request") {
        console.log(`[${result.custom_id}] Validation error - fix and retry`);
      } else {
        console.log(`[${result.custom_id}] Server error - safe to retry`);
      }
      break;
    case "expired":
      console.log(`[${result.custom_id}] Expired - resubmit`);
      break;
  }
}
```

Cancel a Batch

```typescript
const cancelled = await client.messages.batches.cancel(messageBatch.id);
console.log(`Status: ${cancelled.processing_status}`); // "canceling"
```
</doc>

<doc path="typescript/claude-api/files-api.md">
Files API -- TypeScript

The Files API uploads files for use in Messages API requests. Reference files via `file_id` in content blocks, avoiding re-uploads across multiple API calls.

Beta: Pass `betas: ["files-api-2025-04-14"]` in your API calls (the SDK sets the required header automatically).

Key Facts

- Maximum file size: 500 MB
- Total storage: 100 GB per organization
- Files persist until deleted
- File operations (upload, list, delete) are free; content used in messages is billed as input tokens
- Not available on Amazon Bedrock or Google Vertex AI

Upload a File

```typescript
import Anthropic, { toFile } from "@anthropic-ai/sdk";
import fs from "fs";

const client = new Anthropic();

const uploaded = await client.beta.files.upload({
  file: await toFile(fs.createReadStream("report.pdf"), undefined, {
    type: "application/pdf",
  }),
  betas: ["files-api-2025-04-14"],
});

console.log(`File ID: ${uploaded.id}`);
console.log(`Size: ${uploaded.size_bytes} bytes`);
```

Use a File in Messages

PDF / Text Document

```typescript
const response = await client.beta.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  messages: [
    {
      role: "user",
      content: [
        { type: "text", text: "Summarize the key findings in this report." },
        {
          type: "document",
          source: { type: "file", file_id: uploaded.id },
          title: "Q4 Report",
          citations: { enabled: true },
        },
      ],
    },
  ],
  betas: ["files-api-2025-04-14"],
});

console.log(response.content[0].text);
```

Manage Files

List Files

```typescript
const files = await client.beta.files.list({
  betas: ["files-api-2025-04-14"],
});
for (const f of files.data) {
  console.log(`${f.id}: ${f.filename} (${f.size_bytes} bytes)`);
}
```

Delete a File

```typescript
await client.beta.files.delete("file_011CNha8iCJcU1wXNR6q4V8w", {
  betas: ["files-api-2025-04-14"],
});
```

Download a File

```typescript
const response = await client.beta.files.download(
  "file_011CNha8iCJcU1wXNR6q4V8w",
  { betas: ["files-api-2025-04-14"] },
);
const content = Buffer.from(await response.arrayBuffer());
await fs.promises.writeFile("output.txt", content);
```
</doc>

<doc path="typescript/claude-api/streaming.md">
Streaming -- TypeScript

Quick Start

```typescript
const stream = client.messages.stream({
  model: "claude-opus-5",
  max_tokens: 64000,
```

```
  messages: [{ role: "user", content: "Write a story" }],
});

for await (const event of stream) {
  if (
    event.type === "content_block_delta" &&
    event.delta.type === "text_delta"
  ) {
    process.stdout.write(event.delta.text);
  }
}
```

Handling Different Content Types

> **Fable 5 / Claude Opus 5 / Opus 4.8 / Opus 4.7 / Opus 4.6:** Use `thinking: {type: "adaptive"}`. On Claude Opus 5 adaptive is also what you get by omitting `thinking` entirely. On older models, use `thinking: {type: "enabled", budget_tokens: N}` instead.

```typescript
const stream = client.messages.stream({
  model: "claude-opus-5",
  max_tokens: 64000,
  thinking: { type: "adaptive", display: "summarized" }, // display opt-in: default is omitted (empty thinking text) on Fable 5 / Mythos 5 / Claude Opus 5 / Opus 4.8 / 4.7
  messages: [{ role: "user", content: "Analyze this problem" }],
});

for await (const event of stream) {
  switch (event.type) {
    case "content_block_start":
      switch (event.content_block.type) {
        case "thinking":
          console.log("\n[Thinking...]");
          break;
        case "text":
          console.log("\n[Response:]");
          break;
      }
      break;
    case "content_block_delta":
      switch (event.delta.type) {
        case "thinking_delta":
          process.stdout.write(event.delta.thinking);
          break;
        case "text_delta":
          process.stdout.write(event.delta.text);
          break;
      }
      break;
  }
}
```

Streaming with Tool Use (Tool Runner)

Use the tool runner with `stream: true`. The outer loop iterates over tool runner iterations (messages), the inner loop processes stream events:

```typescript
import Anthropic from "@anthropic-ai/sdk";
import { betaZodTool } from "@anthropic-ai/sdk/helpers/beta/zod";
import { z } from "zod";

const client = new Anthropic();
```

```
const getWeather = betaZodTool({
  name: "get_weather",
  description: "Get current weather for a location",
  inputSchema: z.object({
    location: z.string().describe("City and state, e.g., San Francisco, CA"),
  }),
  run: async ({ location }) => `72degF and sunny in ${location}`,
});

const runner = client.beta.messages.toolRunner({
  model: "claude-opus-5",
  max_tokens: 64000,
  tools: [getWeather],
  messages: [
    { role: "user", content: "What's the weather in Paris and London?" },
  ],
  stream: true,
});

// Outer loop: each tool runner iteration
for await (const messageStream of runner) {
  // Inner loop: stream events for this iteration
  for await (const event of messageStream) {
    switch (event.type) {
      case "content_block_delta":
        switch (event.delta.type) {
          case "text_delta":
            process.stdout.write(event.delta.text);
            break;
          case "input_json_delta":
            // Tool input being streamed
            break;
        }
        break;
    }
  }
}
```

Getting the Final Message

```typescript
const stream = client.messages.stream({
  model: "claude-opus-5",
  max_tokens: 64000,
  messages: [{ role: "user", content: "Hello" }],
});

for await (const event of stream) {
  // Process events...
}

const finalMessage = await stream.finalMessage();
console.log(`Tokens used: ${finalMessage.usage.output_tokens}`);
```

Stream Event Types

Event Type	Description	When it fires
`message_start`	Contains message metadata	Once at the beginning
`content_block_start`	New content block beginning	When a text/tool_use block starts
`content_block_delta`	Incremental content update	For each token/chunk
`content_block_stop`	Content block complete	When a block finishes
`message_delta`	Message-level updates	Contains `stop_reason`, usage
`message_stop`	Message complete	Once at the end

````
## Best Practices

1. **Always flush output** -- Use `process.stdout.write()` for immediate display
2. **Handle partial responses** -- If the stream is interrupted, you may have incomplete content
3. **Track token usage** -- The `message_delta` event contains usage information
4. **Use `finalMessage()`** -- Get the complete `Anthropic.Message` object even when streaming. Don't wrap
`.on()` events in `new Promise()` -- `finalMessage()` handles all completion/error/abort states internally
5. **Buffer for web UIs** -- Consider buffering a few tokens before rendering to avoid excessive DOM updates
6. **Use `stream.on("text", ...)` for deltas** -- The `text` event provides just the delta string, simpler
than manually filtering `content_block_delta` events
7. **For agentic loops with streaming** -- See the [Streaming Manual
Loop](./tool-use.md#streaming-manual-loop) section in tool-use.md for combining `stream()` + `finalMessage()`
with a tool-use loop

## Raw SSE Format

If using raw HTTP (not SDKs), the stream returns Server-Sent Events:

```
event: message_start
data: {"type":"message_start","message":{"id":"msg_...","type":"message",...}}

event: content_block_start
data: {"type":"content_block_start","index":0,"content_block":{"type":"text","text":""}}

event: content_block_delta
data: {"type":"content_block_delta","index":0,"delta":{"type":"text_delta","text":"Hello"}}

event: content_block_stop
data: {"type":"content_block_stop","index":0}

event: message_delta
data: {"type":"message_delta","delta":{"stop_reason":"end_turn"},"usage":{"output_tokens":12}}

event: message_stop
data: {"type":"message_stop"}
```
</doc>

<doc path="typescript/claude-api/tool-use.md">
# Tool Use -- TypeScript

For conceptual overview (tool definitions, tool choice, tips), see
[shared/tool-use-concepts.md](../../shared/tool-use-concepts.md).

## Tool Runner (Recommended)

**Beta:** The tool runner is in beta in the TypeScript SDK.

Use `betaZodTool` with Zod schemas to define tools with a `run` function, then pass them to
`client.beta.messages.toolRunner()`:

```typescript
import Anthropic from "@anthropic-ai/sdk";
import { betaZodTool } from "@anthropic-ai/sdk/helpers/beta/zod";
import { z } from "zod";

const client = new Anthropic();

const getWeather = betaZodTool({
  name: "get_weather",
  description: "Get current weather for a location",
  inputSchema: z.object({
    location: z.string().describe("City and state, e.g., San Francisco, CA"),
    unit: z.enum(["celsius", "fahrenheit"]).optional(),
  }),
  run: async (input) => {
    // Your implementation here
    return `72degF and sunny in ${input.location}`;
````
````

```
  },
});

// The tool runner handles the agentic loop and returns the final message
const finalMessage = await client.beta.messages.toolRunner({
  model: "claude-opus-5",
  max_tokens: 16000,
  tools: [getWeather],
  messages: [{ role: "user", content: "What's the weather in Paris?" }],
});

console.log(finalMessage.content);
```

Zod is optional -- `betaTool()` from `@anthropic-ai/sdk/helpers/beta/json-schema` accepts a raw JSON Schema `inputSchema` plus a `run` function if you don't want a Zod dependency.

Key benefits of the tool runner:

- No manual loop -- the SDK handles calling tools and feeding results back
- Type-safe tool inputs via Zod schemas (or raw JSON Schema via `betaTool()`)
- Tool schemas are generated automatically from Zod definitions
- Iteration stops automatically when Claude has no more tool calls

Server tools with the tool runner

The runner's `tools` array accepts raw server-tool definitions (`web_search_20260209`, `web_fetch_20260209`, code execution) alongside runnable tools -- pass the literal tool object; server tools run on Anthropic's servers, so there is no `run` function.

Caution -- the runner does not auto-resume `pause_turn` (as of `@anthropic-ai/sdk` 0.110.0). A long-running server-tool turn can stop with `stop_reason: "pause_turn"`. The runner only continues after a client tool produces a result, so a paused turn ends the loop and is returned as the final message -- no error, no warning, just a silently truncated answer. If you mix server tools into the runner, check `stop_reason` on every iteration and resume by pushing the paused assistant turn back:

```typescript
const params = {
  model: "claude-opus-5",
  max_tokens: 16000,
  tools: [getWeather, { type: "web_search_20260209", name: "web_search", max_uses: 5 }],
  messages: [{ role: "user", content: "Compare this week's forecasts for Paris across two sources" }],
};

const runner = client.beta.messages.toolRunner(params);

// Non-streaming: each iteration yields a complete message
for await (const message of runner) {
  if (message.stop_reason === "pause_turn") {
    runner.pushMessages({ role: "assistant", content: message.content });
  }
}

// Streaming alternative -- construct the runner with `stream: true` (same
// params as above). Each iteration then yields a stream, not a message -- a
// bare `message.stop_reason` check never fires. Resolve the stream first:
const streamingRunner = client.beta.messages.toolRunner({ ...params, stream: true });
for await (const stream of streamingRunner) {
  const message = await stream.finalMessage();
  if (message.stop_reason === "pause_turn") {
    streamingRunner.pushMessages({ role: "assistant", content: message.content });
  }
}
```

Each pause-resume consumes a `max_iterations` tick, so a capped run can still end paused -- check the final message's `stop_reason` before trusting the result (after the loop, call `.done()` on the runner you iterated to get the final message). Alternatively, use the manual loop below, which handles `pause_turn` explicitly.

```
## Manual Agentic Loop

Prefer the tool runner above. Drop to a manual loop only when you need control the runner does not expose
(e.g., a custom transport, request shapes the SDK cannot build, or avoiding a beta dependency -- the runner
is beta, and it supports per-token streaming via `stream: true`). Human-in-the-loop approval does *not*
require a manual loop -- gate inside the tool's `run()` function (return a "user declined" result) or inspect
pending `tool_use` blocks and call `setMessagesParams()` between iterations.

If you do need a manual loop:

```typescript
import Anthropic from "@anthropic-ai/sdk";

const client = new Anthropic();
const tools: Anthropic.Tool[] = [...]; // Your tool definitions
let messages: Anthropic.MessageParam[] = [{ role: "user", content: userInput }];

while (true) {
  const response = await client.messages.create({
    model: "claude-opus-5",
    max_tokens: 16000,
    tools: tools,
    messages: messages,
  });

  if (response.stop_reason === "end_turn") break;

  // Server-side tool hit iteration limit; append assistant turn and re-send to continue
  if (response.stop_reason === "pause_turn") {
    messages.push({ role: "assistant", content: response.content });
    continue;
  }

  const toolUseBlocks = response.content.filter(
    (b): b is Anthropic.ToolUseBlock => b.type === "tool_use",
  );

  messages.push({ role: "assistant", content: response.content });

  const toolResults: Anthropic.ToolResultBlockParam[] = [];
  for (const tool of toolUseBlocks) {
    const result = await executeTool(tool.name, tool.input);
    toolResults.push({
      type: "tool_result",
      tool_use_id: tool.id,
      content: result,
    });
  }

  messages.push({ role: "user", content: toolResults });
}
```

Streaming Manual Loop

Use `client.messages.stream()` + `finalMessage()` instead of `.create()` when you need streaming within a
manual loop. Text deltas are streamed on each iteration; `finalMessage()` collects the complete `Message` so
you can inspect `stop_reason` and extract tool-use blocks:

```typescript
import Anthropic from "@anthropic-ai/sdk";

const client = new Anthropic();
const tools: Anthropic.Tool[] = [...];
let messages: Anthropic.MessageParam[] = [{ role: "user", content: userInput }];

while (true) {
  const stream = client.messages.stream({
    model: "claude-opus-5",
```
```

```
    max_tokens: 64000,
    tools,
    messages,
  });

  // Stream text deltas on each iteration
  stream.on("text", (delta) => {
    process.stdout.write(delta);
  });

  // finalMessage() resolves with the complete Message -- no need to
  // manually wire up .on("message") / .on("error") / .on("abort")
  const message = await stream.finalMessage();

  if (message.stop_reason === "end_turn") break;

  // Server-side tool hit iteration limit; append assistant turn and re-send to continue
  if (message.stop_reason === "pause_turn") {
    messages.push({ role: "assistant", content: message.content });
    continue;
  }

  const toolUseBlocks = message.content.filter(
    (b): b is Anthropic.ToolUseBlock => b.type === "tool_use",
  );

  messages.push({ role: "assistant", content: message.content });

  const toolResults: Anthropic.ToolResultBlockParam[] = [];
  for (const tool of toolUseBlocks) {
    const result = await executeTool(tool.name, tool.input);
    toolResults.push({
      type: "tool_result",
      tool_use_id: tool.id,
      content: result,
    });
  }

  messages.push({ role: "user", content: toolResults });
}
```

> **Important:** Don't wrap `.on()` events in `new Promise()` to collect the final message -- use `stream.finalMessage()` instead. The SDK handles all error/abort/completion states internally.

> **Error handling in the loop:** Use the SDK's typed exceptions (e.g., `Anthropic.RateLimitError`, `Anthropic.APIError`) -- see [Error Handling](./README.md#error-handling) for examples. Don't check error messages with string matching.

> **SDK types:** Use `Anthropic.MessageParam`, `Anthropic.Tool`, `Anthropic.ToolUseBlock`, `Anthropic.ToolResultBlockParam`, `Anthropic.Message`, etc. for all API-related data structures. Don't redefine equivalent interfaces.

Handling Tool Results

```typescript
const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  tools: tools,
  messages: [{ role: "user", content: "What's the weather in Paris?" }],
});

for (const block of response.content) {
  if (block.type === "tool_use") {
    const result = await executeTool(block.name, block.input);

    const followup = await client.messages.create({
```

```
      model: "claude-opus-5",
      max_tokens: 16000,
      tools: tools,
      messages: [
        { role: "user", content: "What's the weather in Paris?" },
        { role: "assistant", content: response.content },
        {
          role: "user",
          content: [
            { type: "tool_result", tool_use_id: block.id, content: result },
          ],
        },
      ],
    });
  }
}
```

Tool Choice

```typescript
const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  tools: tools,
  tool_choice: { type: "tool", name: "get_weather" },
  messages: [{ role: "user", content: "What's the weather in Paris?" }],
});
```

Anthropic-Defined Tools

Version-suffixed `type` literals; `name` is fixed per interface. Web search and code execution are
server-executed; bash and text editor are client-executed (you handle the `tool_use` locally -- see
`shared/tool-use-concepts.md`). Pass plain object literals -- the `ToolUnion` type is satisfied structurally.
The `name`/`type` pair must match the interface: mixing `str_replace_based_edit_tool` (20250728 name)
with `text_editor_20250124` (which expects `str_replace_editor`) is a TS2322.

Don't type-annotate as `Tool[]` -- `Tool` is just the custom-tool variant. Let structural typing infer
from the `tools` param, or annotate as `Anthropic.Messages.ToolUnion[]` if you must:

```typescript
// ? let inference work -- no annotation
const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  tools: [
    { type: "text_editor_20250728", name: "str_replace_based_edit_tool" },
    { type: "bash_20250124", name: "bash" },
    { type: "web_search_20260209", name: "web_search" },
    { type: "code_execution_20260120", name: "code_execution" },
  ],
  messages: [{ role: "user", content: "..." }],
});

// ? this is a TS2352 -- Tool is the CUSTOM tool variant only
// const tools: Anthropic.Tool[] = [{ type: "text_editor_20250728", ... }]
```

Interface	`name`	`type`
`ToolTextEditor20250124`	`str_replace_editor`	`text_editor_20250124`
`ToolTextEditor20250429`	`str_replace_based_edit_tool`	`text_editor_20250429`
`ToolTextEditor20250728`	`str_replace_based_edit_tool`	`text_editor_20250728`
`ToolBash20250124`	`bash`	`bash_20250124`
`WebSearchTool20260209`	`web_search`	`web_search_20260209`

```
| `WebFetchTool20260209` | `web_fetch` | `web_fetch_20260209` |
| `CodeExecutionTool20260120` | `code_execution` | `code_execution_20260120` |

**Don't mix beta and non-beta types**: if you call `client.beta.messages.create()`, the response `content` is
`BetaContentBlock[]` -- you cannot pass that to a non-beta `ContentBlockParam[]` without narrowing each
element.

---

## Code Execution

### Basic Usage

```typescript
import Anthropic from "@anthropic-ai/sdk";

const client = new Anthropic();

const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  messages: [
    {
      role: "user",
      content:
        "Calculate the mean and standard deviation of [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]",
    },
  ],
  tools: [{ type: "code_execution_20260120", name: "code_execution" }],
});
```

Reading Local Files (ESM note)

`__dirname` doesn't exist in ES modules. For script-relative paths use `import.meta.url`:

```typescript
import { readFileSync } from "fs";
import { fileURLToPath } from "url";
import { dirname, join } from "path";

const __dirname = dirname(fileURLToPath(import.meta.url));
const pdfBytes = readFileSync(join(__dirname, "sample.pdf"));
```

Or use a CWD-relative path if the script runs from a known directory: `readFileSync("./sample.pdf")`.

Upload Files for Analysis

```typescript
import Anthropic, { toFile } from "@anthropic-ai/sdk";
import { createReadStream } from "fs";

const client = new Anthropic();

// 1. Upload a file
const uploaded = await client.beta.files.upload({
  file: await toFile(createReadStream("sales_data.csv"), undefined, {
    type: "text/csv",
  }),
  betas: ["files-api-2025-04-14"],
});

// 2. Pass to code execution
// Code execution is GA; Files API is still beta (pass via RequestOptions)
const response = await client.messages.create(
  {
    model: "claude-opus-5",
    max_tokens: 16000,
```
```

```
    messages: [
      {
        role: "user",
        content: [
          {
            type: "text",
            text: "Analyze this sales data. Show trends and create a visualization.",
          },
          { type: "container_upload", file_id: uploaded.id },
        ],
      },
    ],
    tools: [{ type: "code_execution_20260120", name: "code_execution" }],
  },
  { headers: { "anthropic-beta": "files-api-2025-04-14" } },
);
```

Retrieve Generated Files

```typescript
import path from "path";
import fs from "fs";

const OUTPUT_DIR = "./claude_outputs";
await fs.promises.mkdir(OUTPUT_DIR, { recursive: true });

for (const block of response.content) {
  if (block.type === "bash_code_execution_tool_result") {
    const result = block.content;
    if (result.type === "bash_code_execution_result" && result.content) {
      for (const fileRef of result.content) {
        if (fileRef.type === "bash_code_execution_output") {
          const metadata = await client.beta.files.retrieveMetadata(
            fileRef.file_id,
          );
          const downloadResponse = await client.beta.files.download(fileRef.file_id);
          const fileBytes = Buffer.from(await downloadResponse.arrayBuffer());
          const safeName = path.basename(metadata.filename);
          if (!safeName || safeName === "." || safeName === "..") {
            console.warn(`Skipping invalid filename: ${metadata.filename}`);
            continue;
          }
          const outputPath = path.join(OUTPUT_DIR, safeName);
          await fs.promises.writeFile(outputPath, fileBytes);
          console.log(`Saved: ${outputPath}`);
        }
      }
    }
  }
}
```

Container Reuse

```typescript
// First request: set up environment
const response1 = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  messages: [
    {
      role: "user",
      content: "Install tabulate and create data.json with sample user data",
    },
  ],
  tools: [{ type: "code_execution_20260120", name: "code_execution" }],
});

// Reuse container
```

```
// container is nullable -- set only when using server-side code execution
const containerId = response1.container!.id;

const response2 = await client.messages.create({
  container: containerId,
  model: "claude-opus-5",
  max_tokens: 16000,
  messages: [
    {
      role: "user",
      content: "Read data.json and display as a formatted table",
    },
  ],
  tools: [{ type: "code_execution_20260120", name: "code_execution" }],
});
```

Memory Tool

Basic Usage

```typescript
const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  messages: [
    {
      role: "user",
      content: "Remember that my preferred language is TypeScript.",
    },
  ],
  tools: [{ type: "memory_20250818", name: "memory" }],
});
```

SDK Memory Helper

Use `betaMemoryTool` with a `MemoryToolHandlers` implementation:

```typescript
import {
  betaMemoryTool,
  type MemoryToolHandlers,
} from "@anthropic-ai/sdk/helpers/beta/memory";

const handlers: MemoryToolHandlers = {
  async view(command) { ... },
  async create(command) { ... },
  async str_replace(command) { ... },
  async insert(command) { ... },
  async delete(command) { ... },
  async rename(command) { ... },
};

const memory = betaMemoryTool(handlers);

const runner = client.beta.messages.toolRunner({
  model: "claude-opus-5",
  max_tokens: 16000,
  tools: [memory],
  messages: [{ role: "user", content: "Remember my preferences" }],
});

for await (const message of runner) {
  console.log(message);
}
```

````
For full implementation examples, use WebFetch:

- `https://github.com/anthropics/anthropic-sdk-typescript/blob/main/examples/tools-helpers-memory.ts`

---

## Structured Outputs

### JSON Outputs (Zod -- Recommended)

```typescript
import Anthropic from "@anthropic-ai/sdk";
import { z } from "zod";
import { zodOutputFormat } from "@anthropic-ai/sdk/helpers/zod";

const ContactInfoSchema = z.object({
  name: z.string(),
  email: z.string(),
  plan: z.string(),
  interests: z.array(z.string()),
  demo_requested: z.boolean(),
});

const client = new Anthropic();

const response = await client.messages.parse({
  model: "claude-opus-5",
  max_tokens: 16000,
  messages: [
    {
      role: "user",
      content:
        "Extract: Jane Doe (jane@co.com) wants Enterprise, interested in API and SDKs, wants a demo.",
    },
  ],
  output_config: {
    format: zodOutputFormat(ContactInfoSchema),
  },
});

// parsed_output is null if parsing failed -- assert or guard
console.log(response.parsed_output!.name); // "Jane Doe"
```

### Strict Tool Use

```typescript
const response = await client.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  messages: [
    {
      role: "user",
      content: "Book a flight to Tokyo for 2 passengers on March 15",
    },
  ],
  tools: [
    {
      name: "book_flight",
      description: "Book a flight to a destination",
      strict: true,
      input_schema: {
        type: "object",
        properties: {
          destination: { type: "string" },
          date: { type: "string", format: "date" },
          passengers: {
            type: "integer",
            enum: [1, 2, 3, 4, 5, 6, 7, 8],
          },
````
````

```
        },
        required: ["destination", "date", "passengers"],
        additionalProperties: false,
      },
    },
  ],
});
```

Agent Skills

Enable an Anthropic-managed skill (e.g., `pptx`) via `container.skills` + the `code_execution` tool on the beta path. Both beta headers are required. Outputs land as files in the response content -- download by file ID via the Files API.

```typescript
const response = await client.beta.messages.create({
  model: "claude-opus-5",
  max_tokens: 16000,
  container: {
    skills: [{ type: "anthropic", skill_id: "pptx", version: "latest" }],
  },
  tools: [{ type: "code_execution_20260521", name: "code_execution" }],
  betas: ["code-execution-2025-08-25", "skills-2025-10-02"],
  messages: [{ role: "user", content: "Create a 3-slide deck about X." }],
});
// Find the file_id in response.content, then:
// await client.beta.files.download(fileId)
```
</doc>

<doc path="typescript/managed-agents/README.md">
Managed Agents -- TypeScript

> **Bindings not shown here:** This README covers the most common managed-agents flows for TypeScript. If you need a class, method, namespace, field, or behavior that isn't shown, WebFetch the TypeScript SDK repo **or the relevant docs page** from `shared/live-sources.md` rather than guess. Do not extrapolate from cURL shapes or another language's SDK.

> **Agents are persistent -- create once, reference by ID.** Store the agent ID returned by `agents.create` and pass it to every subsequent `sessions.create`; do not call `agents.create` in the request path. **Recommended:** define agents and environments as version-controlled YAML applied with the `ant` CLI -- see `shared/anthropic-cli.md` (its live-docs URL is in `shared/live-sources.md`). The CLI owns the control plane (create/update); your code owns the data plane (sessions with the stored ID). The examples below show in-code creation for when you must provision programmatically; in production the create call belongs in setup, not in the request path.

Installation

```bash
npm install @anthropic-ai/sdk
```

Client Initialization

```typescript
import Anthropic from "@anthropic-ai/sdk";

// Default -- resolves credentials from the environment:
// ANTHROPIC_API_KEY, or ANTHROPIC_AUTH_TOKEN, or an `ant auth login` profile.
// Prefer this for local dev; don't hardcode a key.
const client = new Anthropic();

// Explicit API key (only when you must inject a specific key)
const client = new Anthropic({ apiKey: "your-api-key" });
```

```
## Create an Environment

```typescript
const environment = await client.beta.environments.create(
  {
    name: "my-dev-env",
    config: {
      type: "cloud",
      networking: { type: "unrestricted" },
    },
  },
);
console.log(environment.id); // env_...
```

Create an Agent (required first step)

> ?? **There is no inline agent config.** `model`/`system`/`tools` live on the agent object, not the session.
Always start with `agents.create()` -- the session only takes `agent: { type: "agent", id: agent.id }`.

Minimal

```typescript
// 1. Create the agent (reusable, versioned)
const agent = await client.beta.agents.create(
  {
    name: "Coding Assistant",
    model: "claude-opus-5",
    tools: [{ type: "agent_toolset_20260401", default_config: { enabled: true } }],
  },
);

// 2. Start a session
const session = await client.beta.sessions.create(
  {
    agent: { type: "agent", id: agent.id, version: agent.version },
    environment_id: environment.id,
  },
);
console.log(session.id, session.status);
console.log(`Trace: https://platform.claude.com/workspaces/default/sessions/${session.id}`); // swap
'default' for your workspace ID if the API key is not in the Default workspace
```

With system prompt and custom tools

```typescript
const agent = await client.beta.agents.create(
  {
    name: "Code Reviewer",
    model: "claude-opus-5",
    system: "You are a senior code reviewer.",
    tools: [
      { type: "agent_toolset_20260401", default_config: { enabled: true } },
      {
        type: "custom",
        name: "run_tests",
        description: "Run the test suite",
        input_schema: {
          type: "object",
          properties: {
            test_path: { type: "string", description: "Path to test file" },
          },
          required: ["test_path"],
        },
      },
    ],
```
```

```
  },
);

const session = await client.beta.sessions.create(
  {
    agent: { type: "agent", id: agent.id, version: agent.version },
    environment_id: environment.id,
    title: "Code review session",
    resources: [
      {
        type: "github_repository",
        url: "https://github.com/owner/repo",
        mount_path: "/workspace/repo",
        authorization_token: process.env.GITHUB_TOKEN,
        branch: "main",
      },
    ],
  },
);
```

Send a User Message

```typescript
await client.beta.sessions.events.send(
  session.id,
  {
    events: [
      {
        type: "user.message",
        content: [{ type: "text", text: "Review the auth module" }],
      },
    ],
  },
);
```

> ? **Stream-first:** Open the stream *before* (or concurrently with) sending the message. The stream only delivers events that occur after it opens -- stream-after-send means early events arrive buffered in one batch. See [Steering Patterns](../../shared/managed-agents-events.md#steering-patterns).

Stream Events (SSE)

```typescript
// Stream-first: open stream and send concurrently
const [events] = await Promise.all([
  collectStream(session.id),
  client.beta.sessions.events.send(
    session.id,
    { events: [{ type: "user.message", content: [{ type: "text", text: "..." }] }] },
  ),
]);

// Standalone stream iteration:
const stream = await client.beta.sessions.events.stream(
  session.id,
);

for await (const event of stream) {
  switch (event.type) {
    case "agent.message":
      for (const block of event.content) {
        if (block.type === "text") {
          process.stdout.write(block.text);
        }
      }
```

```
      break;
    case "agent.custom_tool_use":
      // Custom tool invocation -- session is now idle
      console.log(`\nCustom tool call: ${event.name}`);
      console.log(`Input: ${JSON.stringify(event.input)}`);
      break;
    case "session.status_idle":
      console.log("\n--- Agent idle ---");
      break;
    case "session.status_terminated":
      console.log("\n--- Session terminated ---");
      break;
  }
}
```

Provide Custom Tool Result

```typescript
await client.beta.sessions.events.send(
  session.id,
  {
    events: [
      {
        type: "user.custom_tool_result",
        custom_tool_use_id: "sevt_abc123",
        content: [{ type: "text", text: "All 42 tests passed." }],
      },
    ],
  },
);
```

Poll Events

```typescript
const events = await client.beta.sessions.events.list(
  session.id,
);
for (const event of events.data) {
  console.log(`${event.type}: ${event.id}`);
}
```

Full Streaming Loop with Custom Tools

```typescript
function runCustomTool(toolName: string, toolInput: unknown): string {
  if (toolName === "run_tests") {
    // Your tool implementation here
    return "All tests passed.";
  }
  return `Unknown tool: ${toolName}`;
}

async function runSession(client: Anthropic, sessionId: string) {
  while (true) {
    const stream = await client.beta.sessions.events.stream(
      sessionId,
    );

    const toolCalls: Anthropic.Beta.Sessions.BetaManagedAgentsAgentCustomToolUseEvent[] = [];

    for await (const event of stream) {
```

```
      if (event.type === "agent.message") {
        for (const block of event.content) {
          if (block.type === "text") {
            process.stdout.write(block.text);
          }
        }
      } else if (event.type === "agent.custom_tool_use") {
        toolCalls.push(event);
      } else if (event.type === "session.status_idle") {
        break;
      } else if (event.type === "session.status_terminated") {
        return;
      }
    }

    if (toolCalls.length === 0) break;

    // Process custom tool calls
    const results = toolCalls.map((call) => ({
      type: "user.custom_tool_result" as const,
      custom_tool_use_id: call.id,
      content: [{ type: "text" as const, text: runCustomTool(call.name, call.input) }],
    }));

    await client.beta.sessions.events.send(
      sessionId,
      { events: results },
    );
  }
}
```

Upload a File

```typescript
import fs from "fs";

const file = await client.beta.files.upload({
  file: fs.createReadStream("data.csv"),
  purpose: "agent",
});

// Use in a session
const session = await client.beta.sessions.create(
  {
    agent: { type: "agent", id: agent.id, version: agent.version },
    environment_id: environment.id,
    resources: [{ type: "file", file_id: file.id, mount_path: "/workspace/data.csv" }],
  },
);
```

List and Download Session Files

List files the agent wrote to `/mnt/session/outputs/` during a session, then download them.

```typescript
import fs from "fs";

// List files associated with a session
const files = await client.beta.files.list({
  scope_id: session.id,
  betas: ["managed-agents-2026-04-01"],
});
for (const f of files.data) {
  console.log(f.filename, f.size_bytes);
```

```
  // Download and save to disk
  const resp = await client.beta.files.download(f.id);
  const buffer = Buffer.from(await resp.arrayBuffer());
  fs.writeFileSync(f.filename, buffer);
}
```

> ? There's a brief indexing lag (~1-3s) between `session.status_idle` and output files appearing in `files.list`. Retry once or twice if the list is empty.

Session Management

```typescript
// Get session details
const session = await client.beta.sessions.retrieve("sesn_011CZxAbc123Def456");
console.log(session.status, session.usage);

// List sessions
const sessions = await client.beta.sessions.list();

// Delete a session
await client.beta.sessions.delete("sesn_011CZxAbc123Def456");

// Archive a session
await client.beta.sessions.archive("sesn_011CZxAbc123Def456");
```

MCP Server Integration

```typescript
// Agent declares MCP server (no auth here -- auth goes in a vault)
const agent = await client.beta.agents.create({
  name: "MCP Agent",
  model: "claude-opus-5",
  mcp_servers: [
    { type: "url", name: "my-tools", url: "https://my-mcp-server.example.com/sse" },
  ],
  tools: [
    { type: "agent_toolset_20260401", default_config: { enabled: true } },
    { type: "mcp_toolset", mcp_server_name: "my-tools" },
  ],
});

// Session attaches vault(s) containing credentials for those MCP server URLs
const session = await client.beta.sessions.create({
  agent: agent.id,
  environment_id: environment.id,
  vault_ids: [vault.id],
});
```

See `shared/managed-agents-tools.md` ?Vaults for creating vaults and adding credentials.
</doc>

When to Use WebFetch

Use WebFetch to get the latest documentation when:

- User asks for "latest" or "current" information
- Cached data seems incorrect
- User asks about features not covered here

Live documentation URLs are in `shared/live-sources.md`.

Common Pitfalls

- Don't truncate inputs when passing files or content to the API. If the content is too long to fit in the context window, notify the user and discuss options (chunking, summarization, etc.) rather than silently truncating.
- **Prefill removed (Fable 5, Opus 5, Sonnet 5, and the 4.6/4.7/4.8 family):** Assistant message prefills (last-assistant-turn prefills) return a 400 error on Fable 5, Opus 5, Sonnet 5, Opus 4.6, Opus 4.7, Opus 4.8, and Sonnet 4.6. Use structured outputs (`output_config.format`) or system prompt instructions to control response format instead. (One exception: the fallback-credit prefill claim -- when redeeming a credit with `fallback_has_prefill_claim: true`, the server accepts the echoed assistant message; see the migration guide's refusal section.)
- **Confirm migration scope before editing:** When a user asks to migrate code to a newer Claude model without naming a specific file, directory, or file list, **ask which scope to apply first** -- the entire working directory, a specific subdirectory, or a specific set of files. Do not start editing until the user confirms. Imperative phrasings like "migrate my codebase", "move my project to X", "upgrade to Sonnet 4.6", or bare "migrate to Opus 4.8" are **still ambiguous** -- they tell you what to do but not where, so ask. Proceed without asking only when the prompt names an exact file, a specific directory, or an explicit file list ("migrate `app.py`", "migrate everything under `services/`", "update `a.py` and `b.py`"). See `shared/model-migration.md` Step 0.
- **`max_tokens` defaults:** Don't lowball `max_tokens` -- hitting the cap truncates output mid-thought and requires a retry. For non-streaming requests, default to `~16000` (keeps responses under SDK HTTP timeouts). For streaming requests, default to `~64000` (timeouts aren't a concern, so give the model room). Only go lower when you have a hard reason: classification (`~256`), cost caps, deliberately short outputs, or **`max_tokens: 0`** for cache pre-warming (see `shared/prompt-caching.md` -> Pre-warming).
- **Disabling thinking on Claude Opus 5 has two failure modes -- prefer low/medium effort instead.** Only affects code that explicitly opts out; thinking is on by default, so watch for a disabled-thinking setting carried forward from Opus 4.8. With `thinking: {type: "disabled"}`, the model occasionally writes a tool call into its **visible text** instead of a `tool_use` block: the turn succeeds, the call never runs, no error is raised, and in an agentic loop that text pollutes later turns. It can also leak `<thinking>` tags into the response. Turning thinking on and lowering `effort` fixes both and still cuts cost. If a route must stay thinking-off: add *"You may say a brief sentence before using a tool"*, **delete** any don't-think/don't-reason rule (it makes tag leakage worse), and use a generic *"Do not include internal or system XML tags in your response"* rather than naming thinking tags. Details: `shared/model-migration.md` -> Two failure modes when thinking is disabled.
- **128K output tokens:** Fable 5, Opus 5, Opus 4.6, Opus 4.7, Opus 4.8, Sonnet 5, and Sonnet 4.6 support up to 128K `max_tokens`, but the SDKs require streaming for values that large to avoid HTTP timeouts. Use `.stream()` with `.get_final_message()` / `.finalMessage()`.
- **Tool call JSON parsing (Fable 5, Opus 5, and the 4.6/4.7/4.8 family):** Fable 5, Opus 5, Opus 4.6, Opus 4.7, Opus 4.8, and Sonnet 4.6 may produce different JSON string escaping in tool call `input` fields (e.g., Unicode or forward-slash escaping). Always parse tool inputs with `json.loads()` / `JSON.parse()` -- never do raw string matching on the serialized input.
- **Structured outputs (all models):** Use `output_config: {format: {...}}` instead of the deprecated `output_format` parameter on `messages.create()`. This is a general API change, not 4.6-specific.
- **Don't reimplement SDK functionality:** The SDK provides high-level helpers -- use them instead of building from scratch. Specifically: use `stream.finalMessage()` instead of wrapping `.on()` events in `new Promise()`; use typed exception classes (`Anthropic.RateLimitError`, etc.) instead of string-matching error messages; use SDK types (`Anthropic.MessageParam`, `Anthropic.Tool`, `Anthropic.Message`, etc.) instead of redefining equivalent interfaces.
- **Error handling -- catch a chain, not one broad class.** A single `except APIStatusError` / `catch (AnthropicServiceException)` / `rescue APIError` loses the distinction between retryable (429, >=500, network) and non-retryable (400/404) failures. Write a most-specific-first chain -- e.g. `NotFoundError` -> `RateLimitError` -> `APIStatusError` -> `APIConnectionError` (or the Go equivalent: `errors.As` into `*anthropic.Error` then `switch apierr.StatusCode { case 404: ...; case 429: ...; default: ... }`). Per-language class names and namespaces are in `shared/error-codes.md`.
- **Don't research SDK types -- write first.** If a type name isn't shown in the documentation included in this skill, write the code file from the namespace/package tables in the language-specific doc and let the compiler's error point you to the right name. Do not spend turns on WebFetch, SDK-repo clones, or compiling-and-running a separate reflection program to discover type names before writing -- produce the source file first, then fix what the compiler reports. A quick `strings` / `jar tf` / `javap` against the installed SDK is acceptable for locating names (it returns in seconds), but don't escalate beyond that. A file with a wrong type name is recoverable; a session spent on discovery with no file written is not.
- **Bash and text editor tools are Anthropic-defined, schema-less.** Declare `{"type": "bash_20250124", "name": "bash"}` / `{"type": "text_editor_20250728", "name": "str_replace_based_edit_tool"}` -- no `input_schema`. A custom tool with your own schema named `"bash"` is a different tool. Handler paths and security checks are in `shared/tool-use-concepts.md` ? Client-Side Tools.
- **Advisor tool model pairing.** The advisor tool's `model` must be at least as capable as the request's top-level `model` -- e.g. executor `claude-sonnet-5` -> advisor `claude-opus-4-8` or `claude-opus-4-7`. An invalid pair returns 400. Pairing table in `shared/tool-use-concepts.md` ? Advisor. Availability: `shared/platform-availability.md`.
- **Agent Skills != Managed Agents.** To have Claude generate a `.pptx`/`.xlsx`/etc. via Agent Skills, call `client.beta.messages.create` with `container={"skills": [...]}`, the `code_execution_20260521` tool, and

both `code-execution-2025-08-25` + `skills-2025-10-02` betas. Do not use `client.beta.agents` / `sessions` / `environments` here -- those are the Managed Agents surface, not Agent Skills.
- **MCP connector needs both halves.** `mcp_servers=[{type:"url", url, name}]` alone is rejected as a validation error -- also add `tools=[{type:"mcp_toolset", mcp_server_name:<same name>}]` with beta `mcp-client-2025-11-20`. Availability: `shared/platform-availability.md`.
- **`inference_geo` is a direct top-level request parameter** -- `client.messages.create(..., inference_geo="us")` / `.inferenceGeo("us")`. Do not put it in `extra_body` / `putAdditionalBodyProperty`. (Messages API only -- on Managed Agents, `inference_geo` instead nests inside the agent's `model` object, never top-level; see `shared/managed-agents-core.md` ? Pinning inference geography.) Supported on Opus 4.6 / Sonnet 4.6 and later; availability: `shared/platform-availability.md`. `response.usage.inference_geo` reports where inference ran.
- **Fine-grained tool streaming is not a beta feature.** Set `eager_input_streaming: true` on the tool definition and call the regular `client.messages.stream(...)`. There is no beta header and no `client.beta.*` path.
- **Cache diagnostics is beta.** Use `client.beta.messages.*` with beta `cache-diagnosis-2026-04-07`. Pass `diagnostics: {previous_message_id: null}` on the first turn and `diagnostics: {previous_message_id: <previous response id>}` on subsequent turns; the result is on `response.diagnostics`. Availability: `shared/platform-availability.md`.
- **Memory tool type is `memory_20250818`.** Declare `{"type": "memory_20250818", "name": "memory"}`. Go uses the beta-namespace type `{OfMemoryTool20250818: &anthropic.BetaMemoryTool20250818Param{}}` on `client.Beta.Messages.New`; Python/TypeScript/Ruby/PHP/C# use the non-beta `client.messages.create`; Java has both a non-beta `MemoryTool20250818` and a beta tool-runner path. Python/TypeScript provide `BetaAbstractMemoryTool` / `betaMemoryTool` helpers for implementing the backend.
- **Use a model the feature actually supports.** Some features are restricted to specific model tiers -- fast mode is Claude Opus 5 / Opus 4.8 only (and Claude API only), task budgets (Messages API only -- Managed Agents session budgets have no model-tier restriction) are Claude Opus 5 / Fable 5 / Sonnet 5 / Opus 4.8 / 4.7 only, and the advisor tool requires a valid executor<->advisor pair. If the user's prompt names a model that the feature doesn't support, use a supported model instead and note the substitution in the output.
- **Don't define custom types for SDK data structures:** The SDK exports types for all API objects. Use `Anthropic.MessageParam` for messages, `Anthropic.Tool` for tool definitions, `Anthropic.ToolUseBlock` / `Anthropic.ToolResultBlockParam` for tool results, `Anthropic.Message` for responses. Defining your own `interface ChatMessage { role: string; content: unknown }` duplicates what the SDK already provides and loses type safety.
- **Report and document output:** For tasks that produce reports, documents, or visualizations, the code execution sandbox has `python-docx`, `python-pptx`, `matplotlib`, `pillow`, and `pypdf` pre-installed. Claude can generate formatted files (DOCX, PDF, charts) and return them via the Files API -- consider this for "report" or "document" type requests instead of plain stdout text.
- **Server-tool errors don't raise.** Web search and web fetch errors return HTTP 200 with a `web_search_tool_result` / `web_fetch_tool_result` block whose `content` is a single error object (e.g. `{error_code: "max_uses_exceeded"}`) -- not a raised exception. For web search, a success `content` is a *list*; an error `content` is an *object* -- branch on that before indexing.
- **Code execution output block type:** `code_execution_20260521` returns `bash_code_execution_tool_result` (with `.content.stdout`), **not** the legacy bare `code_execution_tool_result`. Iterate `response.content` and match on the correct type.
- **Tool search: never defer everything.** The search tool itself must not have `defer_loading: true`, and at least one tool in `tools` must be non-deferred, or the API returns 400 `All tools have defer_loading set`.

User Request

batch classification of 520k rows, prompt caching, per-call determinism, temperature 0, Message Batches API

--- AUTHOR [2026-08-12 03:55:11] --
This session is being continued from a previous conversation that ran out of context. The summary below covers the earlier portion of the conversation.

Summary:
1. Primary Request and Intent

The session began with a `/catch-up` reconciliation for the project **"2026.07 AI - Political Donation Motive"** (a research project using an LLM to infer why firms donate to political candidates, targeting AFA 2027 special session, submission deadline **2026-08-31**).

Across the session the user's requests were, in order:

1. **Run catch-up reconciliation** -- detect offline work since the last memo, reconcile, record.
2. **AFA provenance catch-up** -- bring the appendix record current (transcripts, session log, human-vs-AI line fractions).
3. **v3 taxonomy decision** -- decide whether party/ideology becomes a category. (Closed as "no.")
4. **Build a gvkey-establishment location dataset for 1997-2024** from Infogroup, saved in `1.Common Dataset\Infogroup`, streaming year-by-year into a ParquetWriter, with updated Python code. Purpose: extend

the geography motive beyond HQ to establishments.
5. **Validate Infogroup HQ against 10-X header HQ data** before use.
6. **Download congressional district shapefiles** (cd107-cd119) into `1.Common Dataset\Politics` as a durable shared asset.
7. **Build a firm-cycle-district sample** = HQ-CD data + selected establishment-CD data at gvkeyxcycle level; sample in `2026.07 AI - Political Donation Motive\Data`, code in `...\Code`.
8. **Update taxonomy and prompts** to remove restrictions on Ways and Means / Appropriations committees.
9. **Redesign the taxonomy** per coauthor's proposal: no priority ordering, multi-label checkboxes, drop incumbent flag.
10. **Determine final v3 taxonomy and columns** for the classification exercise.
11. **Address LLM memory/reproducibility concerns** for full-sample classification.
12. **(Final, unanswered)** "So I think classification_prompt_v3.md is good to use? Then given you suggestions in the last run, how should I use claude for this classification exercise?"

2. Key Technical Concepts

- **LLM-based motive classification** with multi-label (checkbox) taxonomy, no priority ordering
- **Look-ahead bias / pre-election cutoff** -- the project's binding design constraint; cutoff is the cycle's election date
- **`_l1` timing convention** -- committee data uses the *sitting* Congress (period t-1); districts use the *incoming* Congress
- **Redundancy gate** -- testing whether LLM labels are mechanically recoverable from observable indicators
- **Point-in-polygon district assignment** (geopandas `sjoin`, EPSG:4269 NAD83 vs EPSG:4326 WGS84)
- **Census TIGER/Line and PREVGENZ shapefiles** -- TIGER{Y} holds the Congress *sitting* in Y, not elected in Y
- **Infogroup/Data Axle establishment data** -- 22.7 GB parquet, 415M rows, parent_number linkage
- **WRDS via psql** -- `crsp.stocknames`, `crsp.ccmxpf_lnkhist`, `comp.names`
- **Ticker->gvkey matching** -- CRSP/CCM route vs direct Compustat route; share-class normalization
- **Dedup-for-determinism** -- classifying distinct judgment inputs rather than rows

3. Files and Code Sections

`2026.07 AI - Political Donation Motive/STATUS_MEMO.md` (CREATED)
The project's first status memo -- the inter-session channel. Contains all decisions with evidence: reconciliation, provenance corrections, v3 taxonomy decisions, establishment panel construction, threshold tests, reproducibility design.

`2026.07 AI - Political Donation Motive/scripts/line_fractions.py` (CREATED)
Computes AFA appendix (3) human-vs-AI line split via commit trailer + `git blame`, with an OVERRIDES table correcting the `bc3076c` snapshot commit:
```python
OVERRIDES = {
    "AI Talk/_archive/sample_1000_firm_candidate_obs_max100_per_firm_20260727.do": {
        "ai_lines": 33,
        "note": "human 2026-07-22 original; <=33 lines edited by agent 2026-07-27",
    },
}
```
Result: **141 human lines against 2,637 AI (5.1%)**, reported beside **81 human turns / 478 agent tool calls**.

`1.Common Dataset/Infogroup/establishment_footprints/code/1.extract_public_establishments.py` (CREATED)
Two-pass streaming extraction. **Critical guard:**
```python
# Values Infogroup uses to mean "no parent". Anything that is all zeros after
# stripping, plus the empty string.
NULL_PARENTS = {"", "0", "00000000", "000000000", "0000000000"}
```
Output: `infogroup_public_establishments_1997_2024.parquet` -- 21,183,487 rows, 1.24 GB.

`1.Common Dataset/Infogroup/establishment_footprints/code/2.match_establishments_to_gvkey.py` (CREATED)
Ticker->gvkey via two routes (CRSP/CCM, Compustat direct) plus `recover_share_classes()` gated on `NAME_SIM_MIN = 0.90`. Output: `infogroup_gvkey_establishments_1997_2024.parquet` -- **19,895,389 rows, 7,769 gvkeys, 697 MB**, with `is_hq`, `ticker`, `business_status_code`.

`1.Common Dataset/Politics/1.CD Boundary Shapefiles/code/download_cd_shapefiles.py` (CREATED)
```python
CYCLE_TO_CONGRESS = {
    2000: 107, 2002: 108, 2004: 109, 2006: 110, 2008: 111, 2010: 112,
    2012: 113, 2014: 114, 2016: 115, 2018: 116, 2020: 116,  # no cd117 exists
```

```
    2022: 118, 2024: 119,
}
```
Merges to `merged/cd{NNN}.gpkg`, dissolving polygon parts, assigning EPSG:4269 where no `.prj` exists.

`2026.07 AI - Political Donation Motive/Code/2.build_firm_district_panel.py` (CREATED)
```python
JOBS_MIN = 500        # the rule (author, 2026-08-11)
JOBS_ALT = [250, 100]  # looser cuts kept as flags
JOBS_KEEP = min(JOBS_ALT)   # the file's floor
```
Output: `Data/firm_cycle_district_2000_2024.{parquet,dta}` -- **588,479 rows, 12,695 gvkeys**, columns `gvkey cycle cd_state cd_district cd_label in_hq hq_cd_n hq_zip estab_jobs n_estab in_estab_500 in_estab_250 in_estab_100 source`.

`Guidance/classification_prompt_v3.md` (HEAVILY REWRITTEN)
Now ~345 lines, self-contained, no v1/v2 history. Five motive fields table; ?5 output schema; the model fills **eight columns**: `cmte_sector_juris`, `social_tie`, `other`, `motive_detail`, `confidence`, `reasoning`, `search_used`, `sources`.

`Guidance/taxonomy_decisions.md` (v3 section TRIMMED 192->60 lines)
Records the five motive fields and the decisions that shaped them; points to STATUS_MEMO for working-out. v1 and v2 sections untouched.

`Guidance/run_procedure.md` (EXTENDED)
Now: ?1 Run metadata, ?2 After the run -- columns to derive, ?3 Reproducibility at full-sample scale, ?4 Quality checks.

4. Errors and Fixes

1. **Naive `git blame` reported 100% AI** -- fixed with OVERRIDES table in `line_fractions.py`.
2. **CLAUDE.md wrongly said `_archive/` held the PA-stratified version** -- verified archived CSVs are 1,792 rows / 4.7% PA; corrected.
3. **"repeat rate" mislabel** -- the v2 table's 35/20/1/26 is `nth_cycle > 2` (third-cycle rate), not a repeat rate. Relabeled both memo files; deck was already correct.
4. **`parent_number` sentinel** -- 1,993 ticker records carry `'000000000'` in 1998-2002; unguarded matching would attach ~8.6M establishments to those firms.
5. **Legacy build drops HQ records** -- inner join on `(year, parent_number)` dropped 6,759 ticker records with no parent_number.
6. **`comp.company` has no `tic` column** -- used `comp.names`.
7. **Download failure: TIGER2021 is national not per-state** -- regex only matched per-state names; fixed to match both.
8. **Merge failure: `STATEFP10`** -- exact column list broke on cd111's decennial suffix; changed to prefix match.
9. **PREVGENZ has no `.prj`** -- CRS came back `None`; assign EPSG:4269 explicitly.
10. **Shapefiles have one row per polygon part** -- cd107 arrives as 706 rows for 437 districts; dissolve on state x district.
11. **Bash heredoc quoting failures** -- switched to writing Python scripts to the scratchpad and running them.
12. **Verification script bug** -- rebuilt lookup set inside a list comprehension (1,000 rebuilds); rewrote to build once.
13. **Left a background wait-loop running** -- `bsccb6hg3` polled a log for a line that would never appear after the first download failed; stopped with TaskStop.
14. **My own arithmetic error on the W&M rule** -- first said 78 rows would move; geography outranks committee so 8 stay; corrected to **70**.

5. Problem Solving

Establishment geography sizing: median firm covers 57 districts; unrestricted hit rate 33%. Threshold ladder computed. **The coverage gradient was solved by the author's decision to keep 10-X for HQ** -- 94-100% of donation rows now have their firm in the panel, vs 36.7% in cycle 2000 under Infogroup alone.

HQ validation: state 95.8%, ZIP5 84.9%, **same district set 91.3%**, 94.8% agree or within 25 km. Large disagreements are legal-vs-operating HQ (Fairchild: San Jose filing vs South Portland fab).

Ticker reuse errors found: gvkey 038722 (Stem Inc) picks up Microbot Medical; gvkey 039665 (Theseus) picks up Innoviva. Infogroup carries stale tickers. Upper bound ~1.4%.

Redistricting proposal tested and rejected: committee membership is a property of the *person*, unaffected by redistricting; redistricting cycles have *more* open seats (21.3% vs 16.2%); and empirically

0 of 226 incumbent rows would change.

ZIP crosswalk vintage verified: on 181 discriminating cycle-2012 ZIPs, the author's crosswalk matches cd113 (55.8%) over cd112 (37.0%) -- same vintage as the shapefiles.

Reproducibility: full master is **520,011 rows**. Recommended classifying distinct `(hist_gics4, cmte_l1)` pairs once each in fresh contexts, then joining back -- determinism by construction. Dedup on a random 1,000 is only 32% (679 pairs).

6. All User Messages

1. `/catch-up` (skill invocation)
2. "1. Ok, let's use 500 as the threshold. 2. Just want to confirm: cycles correspond to incoming congress and the snapshot of establishments and HQs we use is the even year of that cycle, right?"
3. "I think historical name is ok and even better. 2. So it seems that it's better to use Infogroup HQ data rather than 10-X file one? And then we directly use Census TIGER/Line... Would this way give the best matching result?"
4. "Let's first download 2000-2006 | cd107-cd110 and 2008-2024 | cd111-cd119 shapefiles in G:\...\1.Common Dataset\Politics (you can create a new subfolder), so that I can always use the data for future projects."
5. "1. For cd107-cd110, would it be better to use generalized resolution or match the location based on zip-cd crosswalk files? 2. I feel it may not be correct to consider all establishment locations when evaluating geography donation motive. What will be a good cutoff...?"
6. "OK. You can recompute the menu on polygons. After it, you can do the following things to create the sample: 1. I aggree to use use the generalized shapefiles, not the ZIP crosswalk. 2. I aggre to have thresholds at the district level, not the establishment. Let's use jobs in district >= 250 for establishment to be considered. All HQ location will be considered but we use zip-cd crosswalk + 10-X HQ for the cycle-gvkey-HQ-cd rows because the 10-X HQ information has more data point and it only has ZIP information. So the final sample is the current HQ-CD data + newly created selected establishment-CD data at the GVKEY and cycle level. You can save final sample in \2026.07 AI - Political Donation Motive\Data and code to create the sampe in \2026.07 AI - Political Donation Motive\Code."
7. "1. What does 'both' mean in firm_cycle_district_2000_2024? 2. Is it better to use the 250-job or 500-job threshold?"
8. "1. Ok, let's use 500 as the threshold..." (see #2)
9. "1. Then let's rename in_estab as in_estab_500. 2. How do you know 'Geography under the rule -- in_hq | in_estab -- is 8.0%'? 3. Regarding the inconsistency result you mentioned in the last run, I feel we should use _l1 committee membership assignment rather than _t... I feel the first approach has fewer assumptions? 3. It's OK 22 firms still appear in over 200 districts because it's a fact."
10. "Regarding the inconsistent of redistricting years you found, here is my thought: for non-redistricting years, _l1 committees plus incoming-Congress districts is the combination that assumes least. But for redistricting years... What do you think?"
11. "We also need to make changes to taxonomy_decisions and prompts regarding Ways and Means committees and Appropriations committees. I want to remove the following restrictions... Because these two committees don't oversee specific industries, we don't need to link specific industries to them."
12. "1. I think committee -- sectoral jurisdiction should only capture the committee have jurisdiction over the firm... Also would it be better to have two split variables such as 'committee -- sectoral' and 'committee -- W&M / Appropriations'? 2. If we do what I wrote in 1, do we still need to re-prioritize the ordering? Also I agree the secondary-motive field (motive_2nd) should carry the runner-up rather than reordering the primary"
13. "Yeah, so the ordering I have is something like geography -> committee-sectoral -> committee- W&M / Appropriations -> social ties -> incumbent/contestant. This is the questioN I wanted to ask."
14. "So if a candidate sits on both committee-sectoral and committee- W&M / Appropriations and the donation is not geography motivated, the motive_2nd would be 'committee- W&M / Appropriations', right?... Ways and Means credit may carry firm-specific link, which is just less direct than a sectoral committee."
15. "1.To make 'cmte_sectoral -> cmte_juris' more explict, let's use 'cmte_sectoral -> cmte_sector_juris'. 2. So you think a better version of motive_2nd should to include the next categorical value..."
16. "Obviously the classification rule is the most crucial for this project, so we need to think about it more thoroughly. Here is a question/comment from my coauthor: Whether that is accurate or not depends on the confidence around the secondary motive... My point is basically that we shouldn't have a priority ordering... The more I think about this the more I feel we should drop the incumbent flag and just have the three reasons and an 'other' category, where none of the reasons are ranked and a candidate can check more than one box. What do you think?"
17. "So what will the the updated categories and rules we want to have? Should we have multiple columns (one column for one motive) and tick the column as long as one donation meets the criterion of that column?"
18. "Also I think we can have finer information for 'Other' and combine them later when needed. My coauthor asks for my thoughts, so it's not a decision"
19. "1. What does 'm_' stand for? 2. Do we need to further have cmte_sector_juris and cmte_W&M / Appropriations (or a third cmte_other)? 3. Would it be better to have a other_incumbent and contestant column as well? My idea is we can get sufficient information when assigning the classifications, and we can always aggreate or drop some columns later when we feel doing so."
20. "1. We're doing and updating v3, so it's not v4. 2. I agree with your argument in the last run, so what

would be the columns and key classification decision rules?"
21. "So is the the case that the classification columns we're going to use are m_geography, m_cmte_sector_juris, m_wm_approp, m_other_cmte, m_social_tie, m_incumbant, m_contestant, m_other? And for some variables, we can have details for the evidence."
22. "What do you mean 'merged' in the table? Can you just give a list of classification columns we plan to use?"
23. "We're updating the rule and will use the rule to classifcation all donation records, so nothing to be merged here."
24. "We're determining the taxonomy, so that we can use it for the exercise. The expanation columns should come after those categorical values"
25. "Are the columns too many here?... I don't think it's efficient and feasible to have so many columns to be filled"
26. "v1 and v2 are inputs for v3, not some guidances for v3."
27. "Are you doing taxonomy and column planning??? Can LLMs handle so many columns in the same time? Do we need to so many columns????"
28. "What are you doing???"
29. "Why do you continue throwing me so much information and columns? Do we nee so many columns? I simply want to confirm taxonomy and columns for the exercise"
30. "why do you remove cmte_wm_approp???"
31. "1. why does cmte_sector_juris have _conf? 2. What does other_type mean? 3. What are the all columns we want LLMs to fill?"
32. "1. Why could we have 'no committee has jurisdiction over this firm' for cmte_sector_juris_conf? 2. where did you get the idea of other_type... I don't even think we need to have this variable. We're doing v3 and use v2 as the inputs, why do you keep adding new columns?"
33. "I'm thking about this classification: The motive columns: geography, cmte_sector_juris, cmte_wm_approp, cmte_none_relevant, social_tie, other. The columns is_incumbent and is_contestant can be computed from cand_ici, and cand_powerful_l1 is already in the sample. What do you think?"
34. "We're doing the v3 taxonomy and columns to fill planning."
35. "Is somethign is running? why does it show '1 shell still running'?"
36. "1. What do you mean 'in the file'? 2. We need to discuss and decide the best taxonomy we want to use."
37. "The motive fields I have in mind are: geography, cmte_sector_juris, cmte_wm_approp, cmte_other, social_tie, and other. We can also compute is_incumbent and is_contestant from cand_ici... My idea is we capture slightly more granular information during the initial classification exercise, as we can always aggregate these categories later. What do you think? One question: do you think it would be better to include or exclude the cmte_other column?"
38. "Would it be cleaner and better to not include the cmte_other column?"
39. "I agree with your argument. And this is what I want the LLMs to do: multi-motive + checkbox approach is better. This allows us to flag each applicable motive independently and there will be no need for a priority ordering. So there is no ordering priority for the v3 exercise."
40. "Now that we decide can have the LLMs check off the following categories: geography, cmte_sector_juris, cmte_wm_approp, social_tie, and other, plus is_incumbent, is_contestant, powerful_cand_l1. Let's look at the supportive columns: motive_detail, confidence, reasoning, search_used, source_1-5. Do we need to adjust any of the supportive columns? What's your suggestion on the confidence column?"
41. "1. geography means either donations to a candidate whose district covers either its HQ or has over 250 employees. 2. I agree with your suggestions on confidence and other columns in the last run. I think we can base it and the decisions in the second last run to update v3 and taxonomy_decisions md files."
42. "1. Yes I know it moves the geography rate from 8.0% to 11.3% of donations. But I want to use 250 cutoff. 2. Even if is_incumbent and is_contestant are computed from cand_ici, do we need to have it as a note in v3 prompt in case we forget it after the classification exercise?"
43. "1. I agree to have a run_procedure.md. In that file, do we need to remind the LLMs that firm_cycle_district_2000_2024 in \2026.07 AI - Political Donation Motive\Data is the data it should use for geography motive? Also between firm_cycle_district_2000_2024.dta and firm_cycle_district_2000_2024.parquet, which file will save tokens for LLMs to do the exercise? 2. We're do v3. There is no v4. 3. What does 'which still assumed v2's single motive column' mean?"
44. "1. But an LLM still need to match firm_cycle_district_2000_2024 data with the cycle-gvkey-candidate record data, right? 2. taxonomy_decisions.md should record the taxonomy decisions for each version. We don't need to record all the details when deciding a version. I feel there are too many contennts about v3 taxonomy in it. Should we trim some parts?"
45. "My question is how an LLM will check the geography column in the classification exercise."
46. "One comment I received is the memory issue of LLMs when I ask it to do the classification for the full sample. I think people ask about this question because they worry about how much the classification exercise is reproducible. Do we have such issues when I apply the classification_prompt_v3 to the full sample? Is there a way to somehow alleviate this issue?"
47. **(FINAL)** "So I think classification_prompt_v3.md is good to use? Then given you suggestions in the last run, how should I use claude for this classification exercise?"

7. Pending Tasks

1. **Answer the final question** -- confirm the prompt is ready and give operational guidance on how to run the classification exercise with Claude.

2. **Rebuild the classification input file** -- `AI Talk/random_1000_house_firm_cand_cycle_don_for_classification.csv` (currently 45 columns) still carries `hq_cd_match_cand` and the v1/v2 output columns (`motive`, `motive_detail`, `motive_2nd`, `confidence`). Needs `geography` (join `firm_cycle_district_2000_2024.parquet` on `gvkey x cycle x cand_office_st x cand_office_district`, flag where `in_hq == 1 or in_estab_250 == 1`) and `cmte_wm_approp` (string match on `cmte_l1`), plus the v3 output blanks. Update to `AI Talk/2.add_committee_fields_and_classification_columns.do`.
3. **50-row pilot** before the full pass, checking whether `n_motives` inflates and whether `other` is used as a residual.
4. **Rerun `scripts/line_fractions.py` and `scripts/archive_sessions.py`** before AFA submission (2026-08-31); fill `?` minutes in HUMAN_LOG.md.
5. **Open, not decided:** whether to build firm partisan concentration at t-1 (would unlock ideology as a motive).

8. Current Work

Immediately before the summary request, I had answered the user's reproducibility question by adding **`run_procedure.md` ?3, "Reproducibility at full-sample scale."**

Key findings delivered: the full donation master is **520,011 firm-candidate-cycle rows** (1,592 firms, 3,918 candidates, 12 cycles). Three threats identified in descending seriousness -- order/context dependence from batching ("A row classified after 400 other rows is not being classified the way the same row seen first would be"), non-determinism at temperature 0, and model version drift.

The recommended fix is structural: **classify distinct `(hist_gics4, cmte_l1)` pairs once each in fresh contexts, then join labels back onto all rows**, because `cmte_sector_juris` is a function of (firm's business, candidate's committee set) and doesn't depend on the donation. This gives "determinism by construction: identical inputs cannot receive different labels, because they are not classified twice." Dedup measured at only **32% on a random 1,000** (679 distinct pairs), noted as far larger on the full sample.

Also recommended: **one call per unit with fresh context, never streaming many rows through one conversation**; and four things to report -- rerun agreement (random 200), order effect (should be exactly 100% under per-unit calls), dedup consistency, search sensitivity.

I also fixed run_procedure section numbering (was 1, 2, 4, 5 -> now 1, 2, 3, 4) and committed as `155108b`.

The v3 design as settled:
- **Five motive fields**: `geography` (supplied, `in_hq or in_estab_250`), `cmte_sector_juris` (model), `cmte_wm_approp` (supplied, string match), `social_tie` (model), `other` (model). All five zero is a valid answer.
- **Model fills eight columns**: `cmte_sector_juris`, `social_tie`, `other`, `motive_detail`, `confidence`, `reasoning`, `search_used`, `sources`.
- **No priority ordering.**
- `confidence` scoped to the three model-judged motives only, one 1-5 scale, no ceilings.

9. Optional Next Step

Answer the user's final question directly -- it asks two things: whether `classification_prompt_v3.md` is ready to use, and how to operationally run the exercise with Claude given the reproducibility recommendations.

Verbatim, the user asked: *"So I think classification_prompt_v3.md is good to use? Then given you suggestions in the last run, how should I use claude for this classification exercise?"*

The answer should be **text only, short, and operational** -- the user has repeatedly signalled frustration with volume ("Why do you continue throwing me so much information and columns?", "What are you doing???"). It should cover: (a) confirming the prompt is complete but that the *classification input file* is the blocker not the prompt; (b) the concrete run mechanics -- build the deduplicated pair list, one call per pair in a fresh context, temperature 0, record model ID/date; (c) start with the 50-row pilot before the full pass. No tool calls, no new design, no additional columns.

If you need specific details from before compaction (like exact code snippets, error messages, or content you generated), read the full transcript at: C:\Users\DevinZ\.claude\projects\G--OneDrive---The-Pennsylvania-State-University-PhD-research-projects-2026-07-AI---Political-Donation-Motive\e46c5e60-d793-4cdb-85d3-279ef78aa193.jsonl
Continue the conversation from where it left off without asking the user any further questions. Resume directly -- do not acknowledge the summary, do not recap what was happening, do not preface with "I'll continue" or similar. Pick up the last task as if the break never happened.

--- AGENT [2026-08-12 03:55:36] ----------
Two corrections before the operational answer -- one of them is in a file and would break the run.

--- AGENT   [2026-08-12 03:56:26] ----------------------------------------
Both corrections are in `run_procedure.md` now.

## Is the prompt ready?

Yes -- `classification_prompt_v3.md` is self-contained and complete. **The blocker is the input file, not the
prompt.** `random_1000_house_firm_cand_cycle_don_for_classification.csv` still carries `hq_cd_match_cand` and
the v1/v2 output columns (`motive`, `motive_2nd`), and is missing the two supplied fields v3 depends on:

- `geography` -- join `Data/firm_cycle_district_2000_2024.parquet` on `gvkey x cycle x cand_office_st x
cand_office_district`, flag `in_hq == 1 or in_estab_250 == 1`
- `cmte_wm_approp` -- string match on `cmte_l1`

If the model gets a file without those, it will invent them.

## Two corrections

**Temperature doesn't exist on `claude-opus-5`.** `temperature`, `top_p`, and `top_k` were removed and return
a 400. My earlier `run_procedure.md` ?3 told you to set temperature 0 -- that would have failed every
request. Fixed. Determinism has to come from the dedup design, which is now the only reason that design
matters rather than a nice-to-have.

**Adaptive thinking is on by default** on this model, and `max_tokens` caps thinking *plus* response text
together. Give it room -- 8K is plenty for eight short columns, but don't set 1024.

## How to run it

Not interactively, and not by streaming rows through one conversation. **Message Batches API**, one request
per unit:

| | |
|---|---|
| Endpoint | `client.messages.batches.create(requests=[...])` -- 50% off, up to 100K requests per batch |
| `custom_id` | the `(gvkey, cand_id, cycle)` key, or the dedup pair key. Results come back **in any order**
-- join on `custom_id`, never position |
| `system` | the v3 prompt verbatim, one text block with `cache_control: {"type": "ephemeral", "ttl": "1h"}` |
| `messages` | one user turn holding one record |
| `output_config.format` | a `json_schema` for the eight columns -- guarantees parseable output instead of
hoping for a clean CSV row |
| `model` | `claude-opus-5`, `output_config: {"effort": "high"}` |

Prompt caching is what makes this affordable: the ~350-line prompt is re-sent on every call but read at 0.1x.
Fire one request first and wait for it to start streaming before releasing the rest -- parallel requests
can't read a cache entry that's still being written.

Rough cost, per call: ~$0.0075 batched. 520K rows unduplicated ~= **$4K**; the dedup design cuts that
proportionally. **Web search is the real cost driver** -- $10 per 1,000 searches, so search on every row is
~$5K on top and it's the least reproducible input. Consider enabling it only where the model flags low
confidence, on a second pass.

## The prompt to use

**System block** -- `classification_prompt_v3.md` verbatim, nothing added.
```

User block -- one record, labelled fields, no prose:

```
gvkey: 012141 | firm: MICROSOFT CORP | hist_gics4: 4510 Software & Services
hq: WA-01 (Redmond 98052)
cand_id: H0WA08129 | name: Reichert, David | party: REP | state: WA | district: 08
cand_ici: I | cycle: 2008 | election date: 2008-11-04
cmte_l1: Ways and Means; Homeland Security
cand_power_l1: 0 | cand_ever_power_l1: 0
geography: 0
cmte_wm_approp: 1
donation: $10,000 across 2 quarters | prior-cycle donation: $7,500

Return the eight columns for this record.
```

Field names must match the prompt's ?0 exactly. Nothing post-election goes in the block.

Before the full pass

Run the **50-row pilot** synchronously, not through Batches -- you want to read the output, not just parse it. Two things to check: does `n_motives` inflate above ~1.0 (box-ticking), and is `other` being used as a residual when all five should be zero. Both are cheap to fix in the prompt and expensive to discover after 520K rows.

Want me to write the batch runner and the input-file rebuild?

--- AUTHOR [2026-08-12 03:59:26] ----------
I want to use claude code for this classification and only need to alleviate the reproducable issue. I don't want to spend $4K on this classification exercise.

↪ sity-PhD-research-projects-2026-07-AI---Political-Donation-Mo

--- AGENT [2026-08-12 04:03:19] ----------

Here's the number that matters: **the model's committee judgment is at most ~1,000 distinct decisions for the entire 520K-row sample** -- not 520,000.

Why the exercise is far smaller than it looks

`cmte_sector_juris` asks: does any committee this candidate sits on have jurisdiction over this firm's business? That is a function of exactly two things -- the industry and the committee. There are **38 committees** in the whole 2000-2022 window and **26 GICS4 industry groups**. That's a 26 x 38 grid, 988 cells, of which 469 actually occur in the trial sample.

Build that grid once and `cmte_sector_juris` becomes a join, not a classification. The same grid serves the full sample.

stage	what	how	model calls
A	committee x industry jurisdiction grid	LLM, once	~26
B	`geography`, `cmte_wm_approp`	pure code -- panel join + string match	0
C	`social_tie`, `other`	LLM, row-level	the only real per-row cost

Stage C is smaller than you'd fear too: in v2, `social_ties` fired on **26 of 1,000 rows** (6 primary + 20 secondary), and you already built `social_tie_shortlist_*.csv` to pre-filter it.

Also worth knowing: **v2 never searched -- `search_used` was 0 on all 1,000 rows.** So the $5K web-search line item I quoted was hypothetical. The model doesn't reach for search unless the prompt pushes it.

How to start

1. Rebuild the input file. `2.add_committee_fields_and_classification_columns.do` -- drop the v1/v2 output columns, add `geography` (panel join, `in_hq or in_estab_250`) and `cmte_wm_approp` (string match on `cmte_l1`). No model involved.

2. Build the jurisdiction grid. One subagent per industry, fresh context each, each judging that industry against all 38 committees and returning 38 rows of `{industry, committee, has_jurisdiction, one-line rationale}`. Fresh context per industry is what buys reproducibility -- and unlike a rerun-agreement statistic, you can *audit the whole thing by eye*. 988 cells is a readable spreadsheet.

3. Pilot stage C on 50 rows before committing to the rest.

Two things to decide, and one risk to name

Granularity. GICS4 (26 groups -> 988 cells) is coarse -- "Capital Goods" spans defense primes and farm equipment, which have different committee exposure. GICS6 gives 69 industries -> 2,622 cells, still small enough to build and audit. I'd use **GICS6**; the cost is a bigger grid, not a bigger problem.

Time variation. The grid assumes jurisdiction is stable 2000-2022. Mostly true, but Energy and Commerce's remit and Homeland Security's existence both moved. Either accept it and say so, or build the grid twice (pre/post 2010) and compare -- the disagreement rate is itself a reportable number.

The risk, stated plainly: making this a lookup table makes explicit that `cmte_sector_juris` is a deterministic function of two observables. A referee will say it is an industry x committee interaction that a fixed-effects specification already spans. That is exactly your `gate-measure` question, and this design forces you to answer it rather than letting the LLM's apparent complexity obscure it. Better to face it now -- and the answer, if there is one, has to come from `social_tie` and `other`, which are the only fields carrying information the covariates don't.

Want me to start with the input-file rebuild, or the grid?

--- AUTHOR [2026-08-12 04:05:00] ----------

Should we only care about standing committee and don't need to care about ad hoc (or select/special) committee because only the former has actual power to pass bills?

--- AGENT [2026-08-12 04:05:30] ----------

Mostly right, with three exceptions that matter -- and one of them would be a real error. Let me check the magnitudes before recommending.

--- AGENT [2026-08-12 04:07:04] ----------

No -- the prompt is silent on committee type. It says only "a committee the candidate sits on has jurisdiction," so whatever v1/v2 did with select and joint committees was decided ad hoc, row by row, and never recorded. This is a live choice, and it's better made now, in the grid, than left to per-row improvisation.

Your premise is right for most, and wrong for one

The **Permanent Select Committee on Intelligence** is "select" by name only. It is permanent, it has legislative jurisdiction, and it reports the annual Intelligence Authorization Act -- it authorizes the entire intelligence budget. For defense, aerospace, and IT-services contractors that is a sectoral committee with real money attached.

The data says it isn't redundant either:

committee	rows	also on W&M	also Armed Svcs	caught by `cmte_wm_approp`
intelligence (select)	23	0	9	**2 of 23**
taxation (joint)	15	**15**	0	**15 of 15**
economic (joint)	28	17	1	17 of 28

JCT is perfectly collinear with Ways and Means -- all 15 members are already flagged. Dropping it costs nothing. **Intelligence is the opposite**: 21 of its 23 rows are invisible to the W&M/Appropriations flag, so dropping it discards information nothing else recovers.

The list I'd use -- 21 committees

Keep: the 20 standing committees, **plus Intelligence (select)**.

Drop: Joint Economic, Joint Taxation, Joint Library, Joint Printing, and the ad hoc selects -- Benghazi, Climate Crisis, Energy Independence, Modernization of Congress, 2007 Voting Irregularities. None can report legislation.

Borderline, and I'd drop it: the 2011 Deficit Reduction "supercommittee" (5 rows) did have statutory fast-track authority under the Budget Control Act, so on the merits it belongs. But n=5, it existed for one cycle, and it failed to report. Not worth a special case.

A separate bug you should know about: `cmte_l1` also contains **leadership positions** -- speaker, majority/minority leader, whips, 27 rows in total. Those are not committees and must not enter the jurisdiction grid at all; they're already captured by `cand_power_l1` and `cand_ever_power_l1`. Without an explicit exclusion the grid builder will happily judge whether "majority whip" has jurisdiction over pharmaceuticals.

This cuts the grid from 38 to 21 committees -- 546 cells at GICS4, 1,449 at GICS6.

One caveat worth stating in the paper, not hiding

"Power to pass bills" is a narrower construct than "leverage over the firm." An investigative committee with no legislative jurisdiction can still impose real costs -- hearings, subpoenas, document demands, reputational damage -- and deflecting scrutiny is a documented motive in this literature. Restricting to bill-reporting authority defines the measure as *legislative* access specifically. That's defensible and I'd take it, but say so rather than letting it read as an oversight.

The exposure is small in practice: **0 rows have only select or joint committees** -- every one of the 95 rows with a select/joint committee also sits on at least one standing committee. So this choice moves the binary `cmte_sector_juris` only where the select committee was the sole source of jurisdiction, which after keeping Intelligence is a narrow set.

Want me to write the committee list and this rationale into the v3 prompt and `taxonomy_decisions.md` before we build the grid?

--- AUTHOR [2026-08-12 04:09:49] ----------

I think for leadership positions, we can use all committees because they're leaders. But for committees we should consider, what do you think I should include?

```
--- AGENT   [2026-08-12 04:10:26] ----------------------------------------
Let me size both pieces before answering.
      [action] Bash: cd "C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-Univer⌋
      ↪  sity-PhD-research-projects-2026-07-AI---Political-Donation-Mo

--- AGENT   [2026-08-12 04:11:20] ----------------------------------------
On leadership I'd push back, and the reason is a rule you already adopted.

## Leadership shouldn't enter the grid

Setting `cmte_sector_juris = 1` for leaders is exactly the property that got Ways and Means and
Appropriations *pulled out* of that field in the first place. Your own v3 rationale: the link is real but
identical across firms, which makes it untestable -- a jurisdiction test can only discriminate where
jurisdiction is sectoral. The Speaker's agenda power is the same for Microsoft and for Tyson Foods. It's the
purest possible case of the thing that column is designed not to contain.

It's also already recorded. `cand_power_l1` fires on **140 rows**, and leadership was made a fact-column
rather than a motive for this exact reason -- the same reasoning that demoted incumbency in v3.

The practical stake is small and asymmetric:

- **27 rows** hold a leadership post; **10 of them also hold a committee seat**, so those get judged normally
on that committee. Nothing is lost.
- The remaining **17** -- Speaker, floor leaders, who traditionally hold no committee -- would flip from 0 to
1 on the strength of a fact carrying no firm-specific information. Those 17 rows are precisely the ones that
would make `cmte_sector_juris` more predictable from observables, which is the redundancy gate the paper has
to pass.

Your intuition about the world is right; it's the column that's wrong. Leaders do have power over everything,
and that's `cand_power_l1 = 1`, already there.

## The committees to include -- 19 in the grid

W&M and Appropriations are supplied via `cmte_wm_approp`, so they don't need judging. That leaves:

| tier | committees | rows | expectation |
|---|---|---|---|
| **Sectoral** -- the grid does real work | agriculture, armed services, education & workforce, energy &
commerce, financial services, foreign affairs, homeland security, judiciary, natural resources,
science/space/tech, small business, transportation & infrastructure, veterans affairs, **intelligence
(select)** | most | hits concentrated by industry |
| **Broad power, non-sectoral** | budget, rules | 67, 27 | expect **all-zero** |
| **Investigative** | oversight & government reform | 58 | genuinely open |
| **Internal, no policy jurisdiction** | ethics, house administration | 13, 13 | expect **all-zero** |

**Include all 19 anyway** -- including the ones I expect to come back empty. It costs 5 extra rows x 26
industries = 130 cells, which is nothing, and it converts four assumptions into recorded evidence. An
all-zero Budget row across 26 industries is something you can show a referee; silently dropping Budget is a
decision buried in a script.

State the expectation before you run it, so the empty rows mean something: **budget, rules, ethics and house
administration should come back all-zero.** If they don't, the prompt is over-firing on "jurisdiction" and
that's a QC finding, not a result.

**Oversight and Government Reform is the one I'd flag as genuinely contested.** It has investigative reach
over the whole executive branch and can target any industry, so it isn't sectoral in the way Energy &
Commerce is -- but a pharma firm facing an Oversight pricing investigation has a real and firm-specific
interest. Let the grid decide it rather than deciding it now, and expect to defend whichever way it comes out.

**Grid size:** 19 x 26 GICS4 = **494 cells**, or 19 x 69 GICS6 = **1,311**. Either is one careful pass.

Shall I write the committee list, the leadership exclusion, and the four ex-ante all-zero predictions into
`classification_prompt_v3.md` and `taxonomy_decisions.md` now?

--- AUTHOR  [2026-08-12 04:28:29] ----------------------------------------
1. You can write committee list to classification_prompt_v3.md and taxonomy_decisions.md. 2. We will use
cand_power_l1 to infer the powerful candidate, so we don't need to change things there. 3. My main question
is if I start the exercise in a session, what prompt should I use to start the exercise and alleviate the
```

Done -- all three files.

## What to paste

Start a **fresh** Claude Code session and paste the block in `Guidance/grid_build_prompt.md`. Or, since it's
now on disk, just:

```
Follow Guidance/grid_build_prompt.md.
```

The file is the archived artifact, so the run is reproducible from the repo rather than from your clipboard.

How it solves the memory problem

The memory issue is that a row classified after 400 other rows isn't classified the way the same row seen
first would be. You can't fix that by asking the model to forget. You fix it by never putting two judgments
in the same context:

One subagent per industry	each cell is decided in a context containing no other industry's answer,
and no donation rows at all
Orchestrator judges nothing	it dispatches and collects, so its growing context can't leak into any
judgment
One file per industry	any single industry can be re-run and diffed cell by cell -- the check is
exact, not statistical
The grid is small enough to publish	~1,300 cells at GICS6. A reader audits it directly instead of
trusting a reproducibility statistic

The reason this works at all is the finding from earlier: `cmte_sector_juris` depends only on (industry,
committee), so it was never 520,000 judgments -- it's ~1,300, and the same grid serves the full sample.

Two things before you run it

Pick the granularity. The prompt is written for GICS6 -- 69 industries x 19 committees ~= 1,311 cells, 69
subagent calls. GICS4 would be 26 x 19 = 494. I'd take GICS6; "Capital Goods" spanning defense primes and
farm equipment is exactly the collapse that would make the measure look mechanical.

The input file still needs rebuilding for Stage C, but *not* for this -- the grid only reads `hist_gics6`
from the existing file, which is already there. So you can start the grid now and rebuild the input file in
parallel.

Where this sits

Stage A is what you're starting. Stage B (`geography`, `cmte_wm_approp`) is pure code -- no model. Stage C
(`social_tie`, `other`) is the only genuinely row-level work, and v2 suggests it's small: social ties fired
on 26 of 1,000 rows, and you already have the shortlist files.
```

One caveat I'd keep in view: the second pass in that file gives you a reproducibility number, but reproducibility isn't validity. A grid that reproduces perfectly can still be a re-expression of industry x committee fixed effects. That's the `gate-measure` question, and it stays open until Stage C tells you whether `social_tie` and `other` carry anything the covariates don't.

--- AUTHOR [2026-08-12 04:35:50] ----------
1. I'd like to take GICS6 as well. 2. The updated add_committee_fields_and_classification_columns.do can be saved in G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation Motive\Code\20260812. The generated samples can be saved in G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation Motive\Data\20260812. 2. If I want to also reduce the memory issue, what prompt I should run in a new session. You can tell me the steps to run prompts by setps in a new session

91 shortlisted pairs across the 1,000 rows -- Stage C is small too. Updating the grid prompt's input path, then writing the runbook.
[action] Edit: G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation Motive\Guidance\grid_build_prompt.md
[action] Write: G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation Motive\Guidance\RUNBOOK.md

--- AGENT [2026-08-12 04:39:41] ----------
Everything's written. Here's the sequence.

The runbook -- `Guidance/RUNBOOK.md`

Seven steps, **each numbered step a new session**. That boundary is the whole memory mechanism.

step	session	what
1	Stata, no Claude	run `3.build_classification_sample_v3.do`
2	new	`Follow Guidance/grid_build_prompt.md.` -- 69 industries x 19 committees, one subagent each
3	new	rerun 5 industries blind, report cell-by-cell agreement
4	new, code only	join grid -> rows
5	new	social ties (91 shortlisted pairs, one subagent each) + `other`
6	new, code only	derive `n_motives`, `committee`, assemble
7	new	quality checks + redundancy gate

The full prompt text for steps 3-7 is in the file, ready to paste. Step 2 is the one-liner above.

The rule underneath it: a session that *judges* holds one judgment unit at a time; a session that only *runs code* can be as long as you like. Steps 2, 3 and 5 judge -- they dispatch one subagent per unit and each subagent sees its unit and nothing else. Steps 1, 4, 6 and 7 make no judgments, so their context can't contaminate anything.

```
One clause in step 3 is load-bearing: **do not read the first pass before writing the reruns.** Otherwise the
rerun becomes a consistency check on itself rather than an independent draw, and the agreement number means
nothing.

## What I verified vs. what I didn't

Checked against the data:

- The geography join produces **1,000 rows in, 1,000 out, `geography` = 11.3%** (35 HQ, 90 establishment) --
and at-large districts (code 0) exist on both sides and match, which was the edge case most likely to fail
silently.
- **91 social-tie pairs** are shortlisted across the 1,000 rows, so step 5 is ~91 isolated judgments, not
1,000.
- 69 GICS6 industries -> **1,311 grid cells**.

Not verified: **the `.do` file has not been run.** Agent-side Stata dies on this machine, so I wrote it and
validated the merge logic in pandas, but the Stata syntax itself is untested. Two things I'd watch on first
run -- the `capture confirm string variable cand_office_district` branch (it destrings only if the variable
is stored as a string in the `.dta`, and I couldn't check that), and the `isid` on the district panel before
the join. If either trips, send me the log.

## Two notes on the files

**`hq_cd_match_cand` is kept**, deliberately -- it's the narrow HQ-only measure at 3.9% against `geography`'s
11.3%, and the redundancy gate needs it as a mechanical comparator. I'd flagged it earlier as something to
strip; that was wrong.

**`geography_500` ships alongside** as the tighter robustness contrast (54 rows vs 113), so the 250-vs-500
choice stays testable rather than baked in.

The committee list and its rationale are now in both `classification_prompt_v3.md` (as instructions) and
`taxonomy_decisions.md` (as the decision record with the Intelligence and Joint Taxation numbers). Start with
step 1 whenever you're ready.

--- AUTHOR  [2026-08-12 04:43:16] ----------------------------------------
1. We will only 250 as the cutoff, so don't worry about 500 for now. 2. So essentially it's better to run
seven separate sessions following RUNBOOK.md?

```

```
--- AGENT   [2026-08-12 04:45:13] ----------------------------------------
**1. 250 only.** `geography_500` is gone -- no derived variable, nothing downstream reads it. `in_estab_500`
stays as one raw column carried over from the panel, labelled "(raw, unused)", so the tighter cut is
recoverable without rebuilding. Say the word if you'd rather it not be there at all.

I also noticed you renamed the do-file `3.` -> `2.`, so I read the current version before editing rather than
working from what I'd written, and fixed the stale `3.` reference in the runbook.

**2. Five sessions, not seven.**

| session | steps | why it's separate |
|---|---|---|
| -- | 1 | Stata. Not a Claude session at all. |
| **A** | 2 | judges -- one subagent per industry |
| **B** | 3 | judges, *and* must not see pass 1 before writing its own |
| **C** | 5 | judges -- one subagent per shortlisted pair |
| **D** | 4 + 6 | pure plumbing -- combine them, let it run long |
| **E** | 7 | the adversarial check |

Only **A, B, C** are separate for the memory reason: they make judgments, and a judgment made after 400
others isn't the judgment that would have been made first. B needs the extra boundary because a rerun that
can see the first pass is a consistency check on itself, not an independent draw.

**D is just a join and some arithmetic** -- no judgment, so its context can't contaminate anything. Merging 4
and 6 costs you nothing.

**E is separate for a different reason.** Step 7 runs the redundancy gate, which is the result most likely to
kill the design. A session that has just spent an hour building an artifact reads that artifact charitably --
so give the gate a context with no stake in the answer. That's a discipline argument rather than a mechanical
one, but it's the one I'd least want to skip.

The runbook now leads with this table. Start with step 1 whenever the Stata run is convenient; send me the
log if the `capture confirm string variable` branch or the panel `isid` trips, since those are the two lines
I couldn't test.

      [action] Edit: G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI -
      ↪  Political Donation Motive\Guidance\RUNBOOK.md

--- AGENT   [2026-08-12 04:49:15] ----------------------------------------
**1. Renamed to `1.build_classification_sample_v3.do`.** Your convention is order-within-iteration, and this
is the first script of the 20260812 iteration -- runbook steps 4, 6 and 7 will add `2.`, `3.`, `4.` to the
same folder as they're run.

The one cost of numbering within the iteration is that the folder no longer shows its own upstream
dependencies, so I added a header block naming them: `Code/1.build_exec_roster_l1.py` and
`Code/2.build_firm_district_panel.py` from the prior iteration, neither rerun here, outputs already in
`Data/`.

Heads-up on the folder: the filename bounced between `2.` and `3.` on its own between my commands -- OneDrive
sync churn. Worth a `ls` before you run it in case it drifts again.

**2. I can't run Stata** (agent-side sessions die on this machine), but I tested the risky parts by
replicating them in pandas against the same inputs. Four things now verified rather than assumed:

| check | result |
|---|---|
| geography join | 1,000 rows in -> **1,000 out**, `geography` = **11.3%** (35 HQ, 90 establishment);
at-large districts (code 0) present and matching on both sides |
| panel uniqueness on the 4 join keys | 588,479 rows, **0 duplicates** -> the `isid` will pass and the join
can't fan out |
| `cmte_wm_approp` | **23.4%** -- and I checked the exact entries the string match catches: only
`appropriations`, `ways and means`, and two rows where a whip prefix rides on the same string. **No false
positives.** |
| the `capture confirm string variable` branch | `cand_office_district` is already **numeric** (float64) in
the source `.dta`, so the destring never fires. Harmless as written; I left it as protection if the source
changes. |

That last one resolves the concern I flagged last time -- it won't trip.

I also corrected the runbook: I'd written `cmte_wm_approp ~= 21%` from memory, and it's **23.4%**. The
expected-values table now carries all three numbers so a departure reads as a merge failure rather than
something you have to reason about.

**What's still untested.** Chunks 1, 2 and 2b (committee list, sample merge, GICS backfill) are unchanged
from the script that already produced the existing file, so they're validated by having run. What remains
genuinely unexercised is the *Stata syntax* of the new chunks -- the `joinby ... unmatched(master)
_merge(_mg)`, the `foreach` zero-fill, and the `order ... after(hq_cd_match_cand)`. Those are ordinary
constructions and `hq_cd_match_cand` does exist in the input, so I'd expect a clean run, but I can't claim
it. Send me the log if anything trips.

--- AUTHOR  [2026-08-12 04:52:18] ----------------------------------------
I've run the do file and generated the output samples. Do you need to chech if the output samples are as
expected?

--- AGENT   [2026-08-12 04:52:22] ----------------------------------------
Yes -- I predicted three numbers in advance, so checking them is the whole point.

```

--- AGENT [2026-08-12 04:54:47] ----------

All six pre-registered numbers matched exactly.

check	expected	actual
rows	1,000	**1,000**
`isid gvkey cand_id cycle`	passes	**passes**
`geography` = 1	113 (11.3%)	**113**
-- via `in_hq`	35	**35**
-- via `in_estab_250`	90	**90**
`cmte_wm_approp` = 1	234 (23.4%)	**234**

The Stata run and my pandas replication agree cell for cell, so the constructions I couldn't execute behaved as intended.

Four things I checked after the fact, not predicted:

- **69 GICS6 values, none blank** -> the grid is exactly 19 x 69 = **1,311 cells**, as planned
- **No v1/v2 leftovers** -- `motive`, `motive_2nd`, `source_1`-`5`, `geography_500` all absent; 49 columns
- **All eight model columns blank** on all 1,000 rows
- `cmte_l1`, `cand_power_l1`, `n_cmte_l1`, `hq_cd_match_cand`, `cand_ici`, `hist_gics6` are **byte-identical to the previous build** -- the strongest signal, because it says the new chunks disturbed nothing upstream. `cmte_l1` is blank on 104 rows, matching the count of candidates on no committee.

Nothing failed, so there's nothing to fix.

Two stale references from your folder reorganization. You moved the upstream scripts into `Code/20260812` as `1.` and `2.`, so the do-file is `3.` -- which makes the folder the full pipeline rather than just new work, and reads better. I'd renamed it `1.` on the earlier reading of your convention; that's now corrected in both places, and the header block reads as pipeline position 3 of 4+ rather than pointing at `Code/` root.

I also appended a `STATUS_MEMO.md` entry -- the resizing finding, the committee-scope decision with the Intelligence and Joint Taxation numbers, the all-zero prediction for budget/rules/ethics/house administration, the temperature correction, and the six verified numbers. Step 2 runs in a fresh session with no memory of this one, so the memo is the only thing carrying it forward.

You're clear to start step 2: new session, `Follow Guidance/grid_build_prompt.md.`

--- AUTHOR [2026-08-12 05:03:06] ----------

So do you mean I copy and paste this prompt in a new session? "
Do this immediately, before any analysis. These are one-liners, which is exactly why they get forgotten: nothing breaks if they are missing, the file just quietly lacks them.

column	from
`is_incumbent`	`cand_ici == "I"`
`is_contestant`	`cand_ici != "I"`
`n_motives`	`geography + cmte_sector_juris + cmte_wm_approp + social_tie + other`, or with the two committee fields collapsed to one if reporting four motives
`committee`	`cmte_sector_juris == 1 or cmte_wm_approp == 1`

`cand_power_l1` and `cand_ever_power_l1` are already in the sample -- do not recreate them.

Not stored, computed when needed: the committee diagnostic `n_cmte_l1 > 0 & cmte_sector_juris == 0 & cmte_wm_approp == 0` -- the share of committee-holders the model judged to have no relevant committee. Recompute it from current labels each time, so it cannot go stale if a coding pass is revised."

--- AGENT [2026-08-12 05:03:21] ----------

No -- that's a different numbering scheme colliding, and it's my fault for creating it.

What you pasted is **`run_procedure.md` section 2**, a reference spec for deriving columns *after* labels

exist. It's consumed by **RUNBOOK step 6**, near the end.

RUNBOOK step 2 is the grid build. The whole prompt is:

```
Follow Guidance/grid_build_prompt.md.
```

That's it -- one line in a fresh session. The file you just saw modified is what it reads.

Let me remove the collision so this can't happen again.
[action] Read: G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation Motive\Guidance\run_procedure.md
[action] Edit: G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation Motive\Guidance\run_procedure.md
[action] Edit: G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation Motive\Guidance\RUNBOOK.md
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && grep -n "^## Step" Guidance/RUNBO

--- AGENT [2026-08-12 05:04:01] ----------
Fixed in both files.

What went wrong: two numbering schemes collided. `run_procedure.md` has a section 2 ("columns to derive") and `RUNBOOK.md` has a step 2 ("build the grid"), and they're unrelated. `run_procedure.md` is a reference spec that later steps cite by name -- nothing in it is ever pasted on its own. It now carries a table at the top mapping each section to the runbook step that consumes it, and the runbook says explicitly what to paste and what not to.

What to do now -- new session, paste exactly this:

```
Follow Guidance/grid_build_prompt.md.
```

That one line is the whole prompt. The session reads the file, dispatches 69 subagents (one per GICS6 industry, five at a time), and each returns 19 rows into `Data/20260812/grid/<gics6>.csv`.

The block you quoted comes back at step 6, after labels exist -- and you won't paste it then either. Step 6's block just says "derive per `run_procedure.md` section 2" and the session reads it.

What step 2 should report back, so you can judge whether it worked:

- 1,311 cells, and the share with `has_jurisdiction = 1`
- hit rate per committee
- **whether `budget`, `rules`, `ethics` and `house administration` came back all-zero** -- that's the prediction on record, and any exception has to name a specific stake
- the 10 cells it was least sure of

If the all-zero prediction fails across the board, stop rather than continuing to step 3 -- it means the prompt is reading "jurisdiction" more loosely than intended, and the grid is worth rebuilding before you spend a session measuring the reproducibility of the wrong thing.

--- AUTHOR [2026-08-12 05:07:53] ----------
So you mean copy and paste this in a new session? "Build the committee x industry jurisdiction grid for the donation-motive classification.

Read Guidance/classification_prompt_v3.md first, section `cmte_sector_juris`, for what "jurisdiction" means. Do not reinterpret it -- you are applying that definition, not writing a new one.

What you are building

One row per (industry, committee) pair:

gics6 | gics6_name | committee | has_jurisdiction | strand | note

has_jurisdiction 0 or 1
strand the specific jurisdiction when 1, e.g. "FDA drug approval"; blank when 0

```
  note               <=15 words, why

Committees -- exactly these 19, no others, no substitutions:

    agriculture                     homeland security
    armed services                  house administration
    budget                          intelligence (select)
    education and the workforce     judiciary
    energy and commerce             natural resources
    ethics                          oversight and government reform
    financial services              rules
    foreign affairs                 science, space, and technology
                                    small business
                                    transportation and infrastructure
                                    veterans affairs

Ways and Means and Appropriations are deliberately absent -- they are supplied
separately. Do not add them. Do not add any other select or joint committee.

Industries -- the distinct hist_gics6 values in
Data/20260812/random_1000_firm_cand_cycle_for_classification_v3.csv
(69 of them in the trial sample; 19 x 69 = 1311 cells)

## How to run it -- this part is the whole point

Dispatch ONE SUBAGENT PER INDUSTRY. Each subagent:

  - receives the jurisdiction definition, its single industry, and the 19 committees
  - receives NOTHING about any other industry and no other subagent's output
  - returns exactly 19 rows
  - writes them to Data/20260812/grid/<gics6>.csv

Rules for you as orchestrator:

  - Do not judge any industry yourself.
  - Do not put one subagent's answers into another subagent's prompt.
  - Do not give one subagent two industries.
  - Do not summarise progress in a way that carries judgements forward.

The isolation is what makes this reproducible. Because each cell is decided in a
context containing no other cell, any industry can be re-run independently and
compared cell by cell -- a property no batched pass over donation rows can have.

Run in batches of 5 industries so a failure costs one batch, not the run.

## Constraints

- Judge jurisdiction as it stood 2000-2022. Where a committee's remit changed
  materially in that window, say so in `note` and judge the majority of the period.
- No look-ahead. This is a statement about committee jurisdiction, not about any
  election. Do not consider who won anything, and do not search for election results.
- Broad but firm-invariant power is NOT sectoral jurisdiction. `budget`, `rules`,
  `ethics` and `house administration` are predicted to return 0 for every industry.
  If you credit one, the stake must be specific and named in `strand`.
- `energy and commerce` reaches very widely. Never credit it generically -- always
  name the strand (telecom, electricity/gas, FDA, Medicaid/health insurance,
  consumer protection, environment, interstate commerce).

## When every industry is done

1. Concatenate to Data/20260812/committee_industry_grid.csv
2. Report:
     - total cells, and share with has_jurisdiction = 1
     - hit rate per committee
     - whether budget / rules / ethics / house administration came back all-zero
       as predicted, and every exception with its stated stake
     - the 10 cells you were least sure about
3. STOP. Do not join the grid onto the donation rows."

--- AGENT   [2026-08-12 05:08:05] ----------------------------------------
```

```
Yes -- that's the correct text.

But you don't need to paste it. Both of these do the same thing:

| | |
|---|---|
| **Paste the one line** `Follow Guidance/grid_build_prompt.md.` | session reads the file itself |
| **Paste the full block you just quoted** | same instructions, delivered directly |

I'd use the one-liner: less to mis-paste, and the record is cleaner. For the AFA appendix, "the session was
given `Follow Guidance/grid_build_prompt.md.`" plus that file in git is a complete, unambiguous record of
what ran. If you paste the text and the file is later edited, there's no way to tell which version actually
produced the grid.

Either way, go ahead and start the new session.

--- AUTHOR  [2026-08-12 05:13:45] ----------------------------------------

--- AGENT   [2026-08-12 05:14:26] ----------------------------------------
It's running -- `grid_industries.csv` is written and `grid/` is empty so far.

## Don't go straight to step 3

There's a gate first, and it's cheap. When step 2 reports, check four things before spending a session on
reproducibility:

| check | pass condition |
|---|---|
| **cell count** | 1,311 rows (19 x 69), no industry missing |
| **the ex-ante prediction** | `budget`, `rules`, `ethics`, `house administration` all-zero across every
industry |
| **committee vocabulary** | exactly the 19 names, no drift, nothing invented |
| **energy and commerce** | never credited without a named strand |

**If the all-zero prediction fails broadly, stop and rebuild.** It means the session is reading
"jurisdiction" more loosely than intended, and measuring the reproducibility of a miscalibrated grid tells
you only that it's reliably wrong. A handful of exceptions with specific named stakes is fine -- that's what
the escape clause is for.

I can run this gate **in this session** when it finishes. Reading and tabulating a CSV isn't judging, so
there's no contamination -- and this session never runs step 3 anyway.

## On the table -- which boundaries are real

You asked whether you still need all of them. Honest answer: three are load-bearing, two are discipline.

**Hard requirements:**

- **B separate from A.** A rerun that can see pass 1 isn't an independent draw, and the agreement number
becomes meaningless. This is the one I'd never relax.
- **C separate.** It judges -- 91 shortlisted pairs, one subagent each.
- **A separate.** Already satisfied; it's running now.
```

Judgment calls:

- **D (steps 4 + 6)** is a join and some arithmetic. Combine them, run long, no isolation needed. You could even fold it into another session without harm.
- **E (step 7)** is the one I'd keep separate on principle rather than mechanism. It runs the redundancy gate -- the result most likely to kill the design -- and a context that just spent an hour building the artifact reads it charitably. That's an argument about incentives, not about memory. If you'd rather compress, this is the boundary to drop, and I'd say so plainly rather than pretend it's mechanical.

So the minimum is **A, B, C separate; D and E wherever convenient**. Four sessions if you merge D and E, five if you don't.

The order from here

1. step 2 finishes -> **run the gate** (tell me and I'll do it here)
2. gate passes -> **step 3**, fresh session, blind rerun of 5 industries
3. **step 5**, fresh session, social ties + other
4. **steps 4 + 6**, one session, plumbing
5. **step 7**, the gate on `cmte_sector_juris`

Steps 3 and 5 are independent of each other -- if you want to run them in parallel in two windows, nothing breaks.

--- AUTHOR [2026-08-12 19:40:34] ----------
This is the result of step 2 result: 1. Coverage and hit rate

1,311 cells; 372 with jurisdiction (28.4%). Mean 5.4 committees per industry, median 5, range 2 (Personal Products, Health
Care REITs) to 11 (Oil, Gas & Consumable Fuels).

Output: Data/20260812/committee_industry_grid.csv, plus the 69 per-industry files in Data/20260812/grid/. All 69 passed
structural validation -- 19 rows each, exact committee strings, has_jurisdiction ? {0,1}, strand non-empty exactly where the
cell is 1.

2. Hit rate per committee

committee	n of 69		committee	n of 69
energy and commerce	64 (92.8%)		armed services	19 (27.5%)
judiciary	49 (71.0%)		natural resources	18 (26.1%)
transportation and infrastructure	39 (56.5%)		foreign affairs	16 (23.2%)
homeland security	27 (39.1%)		intelligence (select)	11

```
  |                                                | |     |
| (15.9%)   |

+------------------------------------------------+---------------+-----+--------------------------------------+
-----------+

| 0         |
  | workforce                                      | (33.3%)       |     | administration
|           |

+------------------------------------------------+---------------+-----+--------------------------------------+
-----------+
```

3. The four predicted zeros

All four came back all-zero. 276 cells, no exceptions. No agent credited budget, rules, ethics, or house administration for any industry, though each was free to and several considered it explicitly. The closest near-miss was recorded rather than acted on: the 502010 Media agent flagged house administration as "the strongest candidate anywhere in the economy" -- federal election law is its remit and political advertising is a large biennial revenue line for broadcasters -- and held it at 0 because the rules that bind the broadcaster (lowest unit charge, the political file) are Communications Act, i.e. E&C. The prediction survives.

small business nearly joined them: 2 of 69, both where the SBA program runs through the firm rather than to it (7(a) franchise lending for hotels/restaurants; 7(a) and 504 delivered by bank lenders).

4. Two things that bear on the measure

Energy and Commerce fires for 64 of 69 industries. At 92.8% it is approaching the firm-invariant condition that got Ways and Means merged out of the judged set in the first place. The five zeros are Aerospace & Defense, Air Freight & Logistics, and the three financial industries. Every credited cell names its strand, so splitting E&C by strand costs nothing to run if you want the discrimination back.

One cell is time-varying and the grid records it as a constant. Securities and exchanges jurisdiction moved from Commerce to the new Financial Services Committee in January 2001. Three agents flagged independently -- without seeing each other -- that E&C is a 1 for cycle 2000 and 0 after, for Thrifts & Mortgage Finance, Diversified Financials, and Capital Markets. Cycle 2000 will be mis-scored for those three industries unless the join conditions on cycle.

5. The ten least-certain cells

Ranked by how load-bearing the flag is, using the agents' own words:

1. E&C x the three financial industries -- the 2001 transfer above. The only flag that is a fact rather than a judgement, and the only one that changes with cycle.
2. agriculture x Oil & Gas, Capital Markets, Diversified Financials, the three utilities -- all credited on CFTC/Commodity Exchange Act jurisdiction. The 101020 agent put the objection plainly: "this regulates their trading, not their production; a

```
  stricter reading gives 0." The utilities agents split on it. One convention would move ~6 cells.
  3. education and the workforce x Chemicals, Building Products, Construction & Engineering, Commercial
Services -- all credited
  on OSHA standards written for the industry (PSM, silica, Davis-Bacon). The 151010 agent: "exactly the trap
the definition
  warns against... a reviewer applying the firm-invariance test more strictly would flip this to 0."
  4. armed services x Construction & Engineering -- "rests on scale, not on a clean legal distinction... if
the grid's convention
  is that procurement demand never counts, armed services should flip to 0." The same agent zeroed foreign
affairs, veterans
  affairs and homeland security on identical logic, so this cell defines the demand-channel line for the
whole grid.
  5. transportation and infrastructure x Construction Materials -- the mirror image: credited as a demand
channel while housing
  finance and MILCON were refused. "If the grid's convention is that demand channels never count, T&I should
flip to 0 too."
  6. small business x Hotels, Restaurants & Leisure -- "the Compustat firms in 253010 are large-cap chains,
not small
  businesses; the stake runs through their franchisees rather than the firm itself."
  7. intelligence (select) x Interactive Media -- "the only one where I credited on a rationale different
from the prompt's
  stated one." Credited on FISA ?702 compulsion rather than on budget authorization, and live only from 2008.
  8. science, space, and technology x Biotechnology -- "If the grid is later found to over-credit, this is
the first cell to
  revisit." NIH, the funder that matters, sits with E&C; this rests on DOE/NIST/tech-transfer.
  9. oversight x Pharmaceuticals, Tobacco, Banks, Aerospace, Biotech -- 26 cells credited, and several agents
warned the
  exposure is episodic (crisis-era hearings, 2019-22 drug pricing) while the grid records it as constant
across all twelve
  cycles.
  10. agriculture x Biotechnology = 0 -- flagged because it will look wrong: "the call rests on the
composition of the GICS
  bucket, not on the word 'biotechnology' -- a reader who checks only the industry name will think this row
is wrong."

  Six industries (203030, 251010, 302020, 404020, 451010, 452030) had their agents killed by API limits after
the file was
  written but before the report came back. Their CSVs are structurally clean and used as-is; their
self-reported uncertain
  cells are lost and are not in the list above.

  Recorded in Guidance/_runlog.md, with the exact per-industry prompt preserved in
Guidance/grid_subagent_prompt_template.md so
  any cell can be re-run under identical conditions.

  Stopping here -- the grid is not joined onto the donation rows. The second pass (5 random industries re-run
in a fresh session
  into Data/20260812/grid_rerun/) is the reproducibility statistic and is yours to trigger. What should I do
the next? Should I redo the mapping for these six industries (203030, 251010, 302020, 404020, 451010, 452030)

--- AGENT   [2026-08-12 19:41:20] ----------------------------------------
Two findings in that report matter more than the six industries, and one of them decides whether the measure
survives. Let me measure it before advising.

cswap switch personal

--- AGENT   [2026-08-12 19:57:00] ----------------------------------------
I don't recognize `cswap switch personal` -- it isn't a Claude Code command, and it doesn't match anything in
this project's setup. My guess is it was meant for a different window or tool.

Could you tell me what you're after? If you meant to switch to a different project, directory, or account,
say which and I'll help -- but I'd rather ask than guess at something that might change what I'm working on.
```

Holding your place in the meantime. I'd just measured the Energy and Commerce problem, and the number is the most consequential thing to come out of step 2:

- `cmte_sector_juris` comes out at **52.9%** of rows
- Of the candidates sitting on E&C, **94.3% get a 1** -- so for that group, E&C membership essentially *is* the measure
- **144 rows (27% of all 1s)** are positive only through E&C

That's the grid-building session's own worry confirmed: at 92.8% of industries, E&C is close to the firm-invariant condition that got Ways and Means pulled out of the judged set. It needs a decision from you before step 3 is worth running.

Say the word on `cswap` and I'll pick this back up.

--- AUTHOR [2026-08-12 19:57:21] ----------
what's the login account now?

--- AGENT [2026-08-12 19:57:34] ----------
Let me check what I can actually see.
[action] Bash: ant auth status 2>&1 | head -20; echo "---exit:$?---"
[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - ↪ Political Donation Motive" && echo "git user.name : $(git confi

--- AGENT [2026-08-12 19:57:59] ----------
I can't see it directly -- Claude Code's own login credential isn't exposed to the shell I run in. Here's what I can determine:

`ant` CLI	not installed, so no profile to read
`ANTHROPIC_API_KEY`	**not set**
`ANTHROPIC_PROFILE`	not set
git identity	`Devin Finance <devinzhang99@outlook.com>`
email in my session context	`devinzhang99@outlook.com`

Since no API key or profile env var is set, this session is running on Claude Code's own stored login -- the subscription OAuth credential -- which lives outside anything I can query.

To see the actual account, type `/status` in Claude Code. That's the built-in command that reports the logged-in account and auth method. `/login` switches it.

The git identity and my session email both point at `devinzhang99@outlook.com`, but neither is proof of which Claude account is active -- they're set independently.

If `cswap` is a tool you use to swap between a work and a personal account, it'll have swapped the credential on disk; `/status` will tell you which one took effect. Worth confirming before the next grid session, since a mid-run account switch would change which subscription the step-3 work bills against.

not small
  businesses; the stake runs through their franchisees rather than the firm itself."
  7. intelligence (select) x Interactive Media -- "the only one where I credited on a rationale different
from the prompt's
  stated one." Credited on FISA ?702 compulsion rather than on budget authorization, and live only from 2008.
  8. science, space, and technology x Biotechnology -- "If the grid is later found to over-credit, this is
the first cell to
  revisit." NIH, the funder that matters, sits with E&C; this rests on DOE/NIST/tech-transfer.
  9. oversight x Pharmaceuticals, Tobacco, Banks, Aerospace, Biotech -- 26 cells credited, and several agents
warned the
  exposure is episodic (crisis-era hearings, 2019-22 drug pricing) while the grid records it as constant
across all twelve
  cycles.
  10. agriculture x Biotechnology = 0 -- flagged because it will look wrong: "the call rests on the
composition of the GICS
  bucket, not on the word 'biotechnology' -- a reader who checks only the industry name will think this row
is wrong."

  Six industries (203030, 251010, 302020, 404020, 451010, 452030) had their agents killed by API limits after
the file was
  written but before the report came back. Their CSVs are structurally clean and used as-is; their
self-reported uncertain
  cells are lost and are not in the list above.

  Recorded in Guidance/_runlog.md, with the exact per-industry prompt preserved in
Guidance/grid_subagent_prompt_template.md so
  any cell can be re-run under identical conditions.

  Stopping here -- the grid is not joined onto the donation rows. The second pass (5 random industries re-run
```

```
in a fresh session
  into Data/20260812/grid_rerun/) is the reproducibility statistic and is yours to trigger. What should I do
the next? Should I redo the mapping for these six industries (203030, 251010, 302020, 404020, 451010, 452030)

--- AGENT   [2026-08-12 20:02:25] ----------------------------------------
Picking up where I was. I'd measured the E&C problem; let me finish the diagnostics before advising.
      [action] Bash: cd "C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-Univer⌋
      ↪  sity-PhD-research-projects-2026-07-AI---Political-Donation-Mo

--- AGENT   [2026-08-12 20:03:43] ----------------------------------------
Full picture now. Answering both questions.

## The six industries -- don't redo them

Their files were written **before** the agents were killed, and all six passed the same structural validation
as the other 63. What was lost is the *self-reported uncertainty*, not the labels. Redoing them for
correctness would be re-running work that isn't damaged.

Better use of the same effort: **fold them into step 3's rerun.** You recover their uncertainty flags *and*
get six extra industries of agreement data for free. Keep them separate from the random-5 in the reporting,
though -- the headline reproducibility number has to come from a random draw, or it isn't a statistic.

## The gate result -- the measure survives, but E&C needs your decision

I joined the grid onto the rows as a diagnostic (not the step-4 join -- nothing written):

| | |
|---|---|
| `cmte_sector_juris` | **52.9%** of rows |
| without E&C | 38.5% |
| positive **only** via E&C | **144 rows -- 27% of all 1s** |
| candidates on E&C who get a 1 | **166 of 176 -- 94.3%** |
| candidates *not* on E&C who get a 1 | 363 of 824 -- 44.1% |

That last contrast is the real finding. **For E&C members the grid is nearly deterministic; for everyone else
it genuinely discriminates.** So the measure isn't dead -- but E&C is doing a quarter of the work on its own.

A redundancy preview, using rules with **no industry information at all**:

| rule | reproduces |
|---|---|
| majority class | 52.9% |
| "on E&C" | 62.7% |
| `n_cmte_l1 >= 2` | 66.8% |
| "on E&C or `n_cmte_l1 >= 3`" | **72.0%** |

28% of the label is not recoverable from committee counts and E&C membership. That's a real margin, and it's
the margin the paper lives on. It is not a comfortable one.

**Three options, and I'd take the second:**

1. **Accept it.** E&C really is the broadest committee in the House; 92.8% may simply be true. Cheapest, but
you'll defend that number in every seminar.
2. **Re-run the E&C column alone under a stricter standard** -- credit only where E&C is the firm's *primary*
regulator, not where it has any touchpoint. 69 cells, one focused pass, and it directly tests whether 92.8%
is real breadth or loose crediting. Evidence rather than assumption.
3. **Move E&C to the supplied bucket** with Ways and Means and Appropriations. Consistent with the taxonomy's
own logic, but discards real information.

## Two smaller things

**The demand-channel convention was never specified, and agents split on it.** Uncertain cells 4 and 5 are
the same question answered opposite ways -- `armed services` x Construction & Engineering credited on
procurement demand while the same agent zeroed foreign affairs, veterans affairs and homeland security on
identical logic; `transportation and infrastructure` x Construction Materials credited as demand while
housing finance was refused. That's a prompt gap, not agent error, and it'll show up as spurious disagreement
in step 3. Decide it -- does a committee that drives *demand* count, or only one that *regulates*? -- and
re-run the affected cells.
```

The 2001 securities transfer affects exactly 1 row. Real fact, negligible here: 5 cycle-2000 rows in those three industries, only 1 with a candidate on E&C. Fix it in the join anyway since it's a one-line condition, but it isn't a blocker. One flag: the grid's three financial industries are `402010 Diversified Financial Services`, `402020 Consumer Finance`, `402030 Capital Markets` -- the report called 402020 "Thrifts & Mortgage Finance," which is a different GICS code. Worth a look at whether the right industries were flagged.

Sequencing

Make the E&C and demand-channel decisions before step 3, not after. If you change the convention and re-run cells, the reproducibility statistic should be measured on the final grid -- otherwise you spend a session measuring how reliably you produce something you then discard.

So: decide E&C -> decide demand-channel -> re-run affected cells -> **then** step 3 on the settled grid, with the six killed industries folded in.

--- AUTHOR [2026-08-12 20:06:25] ----------
1. Yes, let's rerun the E&C column alone under a stricter standard. 2. A committee that drives demand count as well. You can update the mapping results before we run step 3.

--- AGENT [2026-08-12 20:06:48] ----------
Both decisions have consequences beyond the cells named in the report -- the demand rule can flip zeros anywhere. Let me scope it against the actual grid before writing the re-run.
[action] Bash: cd "C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-Univer
↪ sity-PhD-research-projects-2026-07-AI---Political-Donation-Mo

--- AGENT [2026-08-12 20:07:47] ----------
Scoped it, and there's a problem with applying "demand counts" literally that I need to flag before running.

137 zeros cite a demand or procurement channel -- but 18 of them are on `budget` and `house administration`, the committees that just passed the all-zero prediction. Their notes zero them on *firm-invariance*, not on demand: `budget` -- *"Aggregate spending totals and procedure; identical for every industry."*

If demand counts without qualification, Budget drives demand for everyone and flips to 1 across all 69 industries -- and so, by the same logic, would Appropriations. That's precisely the failure the taxonomy was built to avoid, and it would undo the one prediction that survived.

The guard I'd apply: demand counts when it is *specific to this industry* (DoD buying ships from shipbuilders), not when the committee's spending role is economy-wide (Budget setting aggregate totals). That keeps your decision intact where it does work and stops it from resurrecting the firm-invariant committees. Say if you'd rather it applied flat.

Scope: this is a full re-run, not a patch

The two changes move in opposite directions:

change	direction	cells at risk
demand counts	**loosens** -- only 0s can become 1s	939 zeros
E&C strict standard	**tightens** -- only 1s can become 0s	64 E&C ones

The 308 non-E&C ones are safe either way. But re-judging 939 zeros is most of the grid, so patching would leave you with cells decided under two different conventions -- and uniformity is the grid's whole value as an auditable artifact.

Re-run all 69 industries under the revised prompt. Same cost as the first pass, one convention throughout. Keep the first grid as `grid_v1/`: the v1<->v2 diff is a free measure of how much the conventions moved, which is worth having when a referee asks how sensitive the measure is to coding choices.

Before I write the revised prompt, one confirmation, because it changes what gets built:
[action] AskUserQuestion:

--- AGENT [2026-08-12 20:10:06] ----------
What would you like to clarify?

Your first answer is recorded -- **demand counts, with the industry-specific guard** -- so `budget`, `rules`, `ethics` and `house administration` stay all-zero and the prediction holds.

The open one is re-run scope. If it helps aim the clarification, the things I'd expect to be behind the hesitation:

- **Cost and time.** The first pass hit API limits hard enough to kill six agents mid-report. A full re-run is 69 subagents again, with the same exposure.
- **Whether it's really necessary.** The 308 non-E&C ones can't flip under a loosening rule, so re-judging them is arguably wasted work -- the counter-argument is uniformity of convention, not correctness of those cells.
- **What happens to the first grid.** Whether v1 is preserved, discarded, or partially reused.
- **Whether the patch could be scoped tighter than ~206 cells** -- for instance re-judging only the 137 demand-flagged zeros plus E&C, and leaving the other 802 zeros alone on the argument that their notes give no demand rationale.

Tell me which of those you're weighing, or ask the question directly.

--- AUTHOR [2026-08-12 20:11:08] ----------
Two questions: 1. Should a committee that drives demand count as well? 2. Should I rerun the whole thing or just patch the affected ones?

--- AGENT [2026-08-12 20:11:35] ----------
Let me check the decisive test case for question 1 before answering it.
[action] Bash: cd "C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-Univer⌋
↪ sity-PhD-research-projects-2026-07-AI---Political-Donation-Mo

--- AGENT [2026-08-12 20:12:30] ----------
That test case changes my answer to question 1.

1. Yes -- but it already does, and that reframes the fix

Look at what the grid does for Aerospace & Defense:

```
[1] armed services      NDAA authorization of weapons procurement, RDT&E
[1] homeland security   DHS procurement and R&D: border surveillance, aviation screening
[1] intelligence        Intelligence Authorization Act: reconnaissance satellites, ISR
[1] science, space      NASA authorization: launch vehicles, human spaceflight
```

Those are **all demand channels**, and all four are credited. Meanwhile:

```
[.] budget    Sets the defense topline as an aggregate function; procedural
[.] rules     Floor procedure only; broad but identical across all industries
```

The agent applied the industry-specific guard spontaneously -- crediting demand where the program is specific to the industry, refusing it where the spending role is economy-wide. **That is exactly the convention I proposed, already operating.**

So the real problem isn't that demand was excluded. It's that the convention was never *written down*, so it held in the clear cases and went both ways at the margin -- Construction & Engineering, Construction Materials. My earlier "137 zeros could flip" overstated it: many of those notes refuse on scope, not on demand (*"Intelligence authorization reaches contractors, not oil"* isn't a demand refusal).

What's needed is one sentence in the prompt, not a new rule. Demand counts when the program is specific to the industry; it does not count where the committee's spending role is economy-wide. That converts an implicit convention into a stated one and makes the marginal cells decidable.

2. Patch -- and I've changed my mind since the last message

I argued for a full re-run on uniformity grounds. The defense row undercuts that: the convention *was* applied consistently where it matters, so the grid isn't the two-convention mess I feared. Two targeted passes:

pass	cells	why
E&C column	69	strict standard -- this is a genuine tightening and every E&C cell needs re-judging
demand-boundary cells	~30-60	only cells whose note shows a demand-based *refusal*, not a scope refusal. I'd produce the list and you'd see it before anything runs

That's roughly 130 cells against 1,311 -- and it dodges the API-limit exposure that killed six agents on the full pass.

Two things make patching safe here that weren't true when I recommended otherwise:

- **A loosening rule can't flip 1s to 0s**, so all 372 credited cells stand regardless -- except E&C, which is being tightened and is in the patch.
- **The 802 unflagged zeros** were refused on scope or on firm-invariance, both untouched by either change.

The residual risk I'd own: notes are <=15 words, so a demand rationale might exist in a cell whose note didn't say "demand." I'd rather find those by reading the candidate list than assume the regex caught everything -- which is why I want you to see the list before it runs.

Proposed order: I write the one-sentence convention into the prompt, generate the demand-boundary candidate list for you to check, then run both passes with `grid_v1/` preserved. Want me to start with the candidate list?

--- AUTHOR [2026-08-12 20:14:37] ----------
1. OK, you can add the one sentence in the prompt. 2. Yeah you can generate the demand-boundary candidate list for me to
check.

24 clean candidates, written to `Data/20260812/demand_boundary_candidates.csv`. But there's a second tier I need you to see before deciding scope.
[action] Bash: cd "C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-University-PhD-research-projects-2026-07-AI---Political-Donation-Mo

--- AGENT [2026-08-12 20:16:06] ----------
My tier-1/tier-2 split was an artifact -- the regex missed "not **sectoral**", which is the phrase several genuine demand refusals use ("VA facility construction is minor procurement, not sectoral jurisdiction"). Regenerating on an honest boundary.
[action] Bash: cd "C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-University-PhD-research-projects-2026-07-AI---Political-Donation-Mo

--- AGENT [2026-08-12 20:16:47] ----------
Both done. The convention sentence is in `grid_build_prompt.md` and `classification_prompt_v3.md`, and the candidate list is at `Data/20260812/demand_boundary_candidates.csv`.

What to check -- 136 cells

The file has one row per candidate with its full note, sorted so the clearest cases come first. Two columns matter:

`weighs_and_refuses`	count	what it means
`True`	**47**	the note explicitly acknowledges a purchase relationship and declines it -- *"Military construction is a demand channel, not remit over materials manufacturing"*
`False`	89	demand vocabulary appears but the refusal may be about scope -- *"biotechnology firms are not intelligence contractors"*

The 47 are where I'd expect most of the flipping. The 89 are included because I no longer trust the wording to separate them -- the split I gave you last message was wrong, and I'd rather over-include and let the re-run decide than filter on a regex I've already seen fail.

Concentration by committee, which is a useful sanity check in itself:

```
armed services  34    veterans affairs  16    small business   8
intelligence    27    oversight         12    natural res.     7
```

Armed Services and Intelligence together are 45% of the list -- both are procurement-heavy committees, so that's the pattern you'd predict if the convention gap is real.

Total patch scope: 136 + 69 E&C = 205 cells, 16% of the grid.

A correction worth being explicit about

I told you last message there were 24 candidates. That was wrong -- the regex missed `not sectoral`, which is exactly the phrase several genuine demand refusals use. The real figure is 136 on an inclusive boundary. The 24 weren't a different *kind* of case, just the ones that happened to use vocabulary my pattern caught.

That failure is also the argument for the inclusive boundary: I can't reliably separate demand refusals from scope refusals by wording, so the re-run should see anything where a commercial relationship was noticed at all. The 527 zeros that never mention demand are genuinely out of reach of the new convention.

What I'd suggest you look at

Not all 136 -- skim the 47 `True` rows, and specifically these three, because they set precedents the rest follow:

- **`armed services` x Construction Materials** (MILCON) and **x Airlines** (Civil Reserve Air Fleet) -- both named, industry-specific programs. If these don't flip, the guard is being read too tightly.
- **`armed services` x Oil & Gas** (*"DoD is a fuel customer"*) -- the hardest case. DoD buys enormous quantities of fuel, but "the government is a large customer" is something many industries could say, so it may fail the same-words test.
- **`intelligence` x Semiconductors** (*"buys defense-grade parts indirectly"*) -- tests whether indirect demand counts.

Tell me when you've looked, and I'll write the two re-run prompts -- E&C column under the strict standard, and the 136 under the stated convention -- with `grid_v1/` preserved so the diff is recoverable.

--- AUTHOR [2026-08-12 20:20:23] ----------
One more general question in this case: is it better to use GICS4 or GICS6 industry to map industries and committees in this case?

--- AGENT [2026-08-12 20:20:46] ----------
Good question, and it's now answerable with evidence rather than priors. The decisive test is whether GICS6 cells *disagree within* their GICS4 parent -- if they don't, the finer grid is costing 2.7x the cells for nothing.

[action] Bash: cd "C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-Univer⌋
↪ sity-PhD-research-projects-2026-07-AI---Political-Donation-Mo

--- AGENT [2026-08-12 20:21:08] ----------
Now the row-level consequence -- how much the measure itself moves if you collapse to GICS4.

[action] Bash: cd "C:/Users/DevinZ/AppData/Local/Temp/claude/G--OneDrive---The-Pennsylvania-State-Univer⌋
↪ sity-PhD-research-projects-2026-07-AI---Political-Donation-Mo

--- AGENT [2026-08-12 20:21:50] ----------
GICS6 -- and the evidence is stronger than I expected.

The case, in two numbers

Within-GICS4 disagreement. Of the 380 `(GICS4 x committee)` cells that have more than one GICS6 child, **106 (27.9%) have children that disagree.** More than a quarter of the time, collapsing to GICS4 forces one answer onto industries the grid judged differently.

Where it disagrees is exactly where you'd want it to:

```
oversight and government reform   65%    energy and commerce      20%
agriculture                       55%    intelligence (select)    20%
armed services                    50%    veterans affairs         10%
homeland security                 50%    budget / rules / ethics   0%
education and the workforce       50%    house administration      0%
```

The four firm-invariant committees disagree **0%** of the time -- they're uniformly zero, so there's nothing to lose. The sectoral committees disagree constantly. That's the pattern that tells you the granularity is tracking something real rather than noise.

The asymmetry that settles it

Collapsing to GICS4 moves 77 rows (7.7%), and **every single one moves in the same direction**:

	rows
GICS4 says 1, GICS6 says 0	**77**
GICS4 says 0, GICS6 says 1	**0**

Coarseness only ever manufactures false positives. It never recovers a true positive GICS6 missed -- which follows mechanically from the any-child rule, but the magnitude doesn't: it would push `cmte_sector_juris` from 52.9% to 60.6% purely by attributing one sub-industry's committee exposure to its neighbours. Defense primes' Armed Services jurisdiction would spread across all of Capital Goods.

That is the opposite of what this measure needs. Its only defence against the redundancy gate is firm-specificity, and GICS4 spends 77 rows of it to save 817 cells.

What GICS4 would have bought

494 cells instead of 1,311 -- about 38% of the work. Real, but the cost is paid in the exact currency the paper is short of. And the marginal cells are cheap: they're the ones where the answer is obvious, since the four all-zero committees alone are 276 of the 1,311.

One honest caveat

This test is partly circular. The grid was *built* at GICS6, so of course its cells disagree within GICS4 -- a grid built at GICS4 would have made one call per group and never revealed the tension. What the 27.9% shows is that independent agents, judging sibling industries without seeing each other, reached different conclusions more than a quarter of the time. That's evidence the heterogeneity is real rather than an artifact of finer bins, but it isn't proof, and a referee could press on it.

The clean answer if it's ever challenged: report the GICS4-collapsed measure as a robustness row. You can produce it from the existing grid in one line -- no re-judging needed -- which is a nice property of having built at the finer level. The reverse is not available.

--- AUTHOR [2026-08-12 20:26:50] ----------
I think I agree with the FALSE results in demand_boundary_candidates.csv, then what should we do the next?

--- AGENT [2026-08-12 20:27:08] ----------
Then the patch scope drops to the 47 explicit demand refusals plus the E&C column. Let me size the pass before writing it.

↪ Political Donation Motive\Guidance\RUNBOOK.md

--- AGENT [2026-08-12 20:28:41] ----------
Ready to run. Here's what's set up.

Next: step 2b, new session

```
Follow Guidance/grid_rejudge_prompt.md.
```

116 cells across 69 industries -- every industry gets a subagent for its E&C cell, and 32 of them also carry demand cells. Median 1 cell per industry, max 5 (Construction & Engineering).

what	cells
`energy and commerce`, strict "principal authority" standard	69
demand refusals you agreed need re-judging (`weighs_and_refuses = True`)	47
the 89 you agreed with	**untouched**

v1 is preserved -- `Data/20260812/grid_v1/` (69 files) and `committee_industry_grid_v1.csv`. Nothing in the re-run overwrites them.

Two design choices worth knowing about

Subagents don't see v1's answer for the cell they're judging. I made this explicit in the prompt and told the orchestrator not to read prior answers before dispatching. If a subagent sees "you said 0 because X," the task becomes *do you want to change your mind?* and the diff measures reluctance rather than the effect of the convention. Same reasoning as the blind rerun in step 3.

The strict E&C standard is operationalized as a question, not a definition: *if this industry's general counsel named the three committees whose actions most shape the business, would E&C be among them?* Definitions of "primary regulator" invite lawyering; that question is answerable. It explicitly excludes the three peripheral patterns that drove the 92.8% -- environmental rules reaching every manufacturer, consumer-protection statutes reaching every seller, health-program strands where the industry is one payer among many.

What the report should tell you

- **E&C hit rate, before and after, out of 69.** This is the number the whole exercise turns on.
- **How many of the 47 flipped 0 -> 1.**
- **Any cell moving 1 -> 0 outside E&C** -- there should be none, since the demand convention only loosens. If one appears, something's wrong with the pass, not with the cell.

Then re-run the diagnostic that started this: on v1, **27% of positive rows were positive only through E&C**, and **94.3% of E&C members scored 1**. If the strict standard hasn't moved those, the tightening didn't work and we should talk about option 3 -- moving E&C to the supplied bucket alongside Ways and Means.

One thing I'd flag before you start

The six industries that lost their agents to API limits last time are named in the prompt, with instructions to re-dispatch only industries whose file is missing or malformed. But four of the six (`203030`, `302020`, `451010`, `452030`) are in this worklist anyway -- so they'll get a fresh agent regardless, and their lost uncertainty flags come back for those cells at no extra cost.

`RUNBOOK.md` now has this as **step 2b**, sequenced before step 3 with the reason stated: measuring the reproducibility of a grid you're about to revise wastes the session.

--- AUTHOR [2026-08-12 20:31:05] --
So I should add this prompt "Follow Guidance/grid_rejudge_prompt.md.
```

Added 2026-08-12 after the v1 grid exposed two problems: `energy and commerce` fired for 64 of 69 industries (approaching the firm-invariant condition), and the demand-channel convention was never stated so agents split on it at the margin.

116 cells -- the 69 E&C cells under a strict "principal authority" standard, plus the 47 zeros whose notes explicitly weigh a demand relationship and refuse it. The other 89 demand-mentioning zeros were reviewed and confirmed as scope refusals (author, 2026-08-12), so they stand.

v1 is preserved at `grid_v1/`. **Run this before step 3** -- measuring the reproducibility of a grid you are about to revise wastes the session." in a new session to start step 2b?

--- AGENT   [2026-08-12 20:31:13] ----------------------------------------
No -- just the one line:

```
Follow Guidance/grid_rejudge_prompt.md.
```

Everything after the closing ` ``` ` is RUNBOOK annotation written for you -- what the step is, why it exists, that v1 is preserved. The session doesn't need it and reading it would only prime the orchestrator with conclusions it should reach from the data.

The rule for every step in RUNBOOK.md: paste what's inside the fence, nothing outside it. That's what the "What you actually paste" section near the top is trying to say, and this is the second time the boundary hasn't been clear -- so it's the note that needs fixing, not your reading of it.

[action] Edit: G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation Motive\Guidance\RUNBOOK.md
```

```
--- AGENT   [2026-08-12 20:31:24] ----------------------------------------
The RUNBOOK now shows the layout explicitly, so the boundary is visible rather than something you have to
infer.

**Go ahead and start step 2b** -- new session, that one line.

================================================================================================================
SESSION 3 of 11   807e833a-746f-4227-ae02-2159b0b5a7ef
================================================================================================================

# Session catch-up (reconciliation) routine

Memos are written by Claude sessions; the user works between sessions
(reviewing, rerunning in Stata, editing scripts, changing decisions).
NEVER treat the memo's NEXT line or recorded results as current state
without reconciling first.

## 1. Establish the memo baseline
Read the project status memo's latest entries and its NEXT line; note the
date of the last recorded entry.

## 2. Detect offline work
Scan for files modified AFTER the last memo entry date (code folders,
output tables, drafts, the memo itself):
- Git Bash: `find <code/output/writeup dirs> -newermt "YYYY-MM-DD" -type f`
  (or compare mtimes with `ls -lt | head`).
- If the code folder is a git repo: `git status` + `git diff` against the
  last session's commit gives EXACT deltas -- prefer this when available.

## 3. Reconstruct, then confirm (do NOT ask the user to enumerate)
The user makes many changes between sessions -- major and minor mixed --
and should not have to list them. READ the changed files and reconstruct
the changelog yourself:
- Changed scripts: read them and compare specifications, variable
  definitions, and windows against what the memo describes.
- Regenerated outputs: compare key coefficients in current result files
  against the numbers recorded in the memo.
- Drafts: skim changed sections (python-docx for .docx).
Classify each change MAJOR (decision, specification, sample, or results
changed) or MINOR (refactoring, formatting, table cosmetics). Present the
reconstructed changelog in that order and ask the user only two things:
(a) is this reading correct, and (b) the WHY behind major changes that
cannot be inferred from the files. Without version control the diff is
against the memo's description, not the true prior file -- flag
reconstructions that are uncertain rather than guessing.

## 4. Record the reconciliation
Append a short memo entry: "User offline work since <date>: <changes>;
NEXT revised to: <...>" -- so the offline work enters the inter-session
record. Tombstone depth unless the user's changes are substantive.

## 5. Protect user modifications
Before editing ANY file this session, re-read its current content -- never
edit from memory of a previous session's version. If a script differs
from what the memo describes, the user's version wins; flag the
discrepancy instead of "fixing" it back.

## 6. Then proceed
Only after 1-5, act on the (possibly revised) NEXT line or the user's
stated task.

--- AGENT   [2026-08-12 04:57:29] ----------------------------------------
## Catch-up: no offline work to reconcile

The previous session ended at **00:53 today**, three minutes ago. Every uncommitted file carries a timestamp
from that session (00:28-00:54), and the memo's 2026-08-12 entry -- itself uncommitted -- already describes
all of it. Nothing changed on disk between then and now, so there is no author changelog to reconstruct and
I'm not appending a "no changes" entry to an append-only log.

**Uncommitted state, all last session's own output:**

| | |
|---|---|
| `Code/20260812/` (new) | `1.build_exec_roster_l1.py`, `2.build_firm_district_panel.py` moved here from
`Code/`; `3.build_classification_sample_v3.do` new |
| `Data/20260812/` (new) | `random_1000_firm_cand_cycle_for_classification_v3.{csv,dta}`, 49 cols |
| `Guidance/` | `RUNBOOK.md` + `grid_build_prompt.md` new; v3 prompt, taxonomy and run_procedure edited |
| `STATUS_MEMO.md` | +63 lines -- the 2026-08-12 entry |

Worth committing before the run starts, so step 2's output is a clean diff against a recorded baseline.

**NEXT, unchanged:** RUNBOOK step 2 -- build the 19 x 69 jurisdiction grid, one subagent per industry.

### One defect found, and it would misfile the run's output

The two files disagree on where the grid goes:

- `RUNBOOK.md` step 2 -> `Data/20260812/grid/<gics6>.csv` -> `Data/20260812/committee_industry_grid.csv`
- `grid_build_prompt.md` (the paste block, lines 57 and 87) -> `Data/grid/<gics6>.csv` ->
`Data/committee_industry_grid.csv`

The paste block is what a fresh session actually receives, so as written the grid lands outside the dated
folder, and steps 3 and 4 -- which both name the `20260812` paths -- would not find it. The dated folder is
right. Also `grid_build_prompt.md` line 47 names the input under `Data/20260812/`, so the file is already
inconsistent with itself.

Want me to fix the two paths in `grid_build_prompt.md` and commit the pending work, or leave both to you?

On isolation: this session has read the memo, but the grid's isolation property lives in the per

```

```
--- AGENT   [2026-08-12 05:01:31] ----------------------------------------
Finishing the sentence you cut off, then what I did:

**On isolation.** This session has now read the memo, including the ex-ante prediction that `budget`,
`rules`, `ethics` and `house administration` return all-zero. That does not compromise step 2, because the
grid's isolation property lives in the per-industry subagents, not in the orchestrator: each subagent gets
the jurisdiction definition, one industry and the 19 committees, and nothing else. The prediction is already
written into the paste block anyway (line 79), so a "clean" orchestrator would hand it over regardless. What
this session must not do is judge any cell itself or carry one industry's answer into another's prompt --
both already forbidden in the RUNBOOK's step-2 row.

**Path defect fixed** in `Guidance/grid_build_prompt.md` -- three lines now point at the dated folder,
matching the RUNBOOK and steps 3-4:

- subagent output -> `Data/20260812/grid/<gics6>.csv`
- concatenation -> `Data/20260812/committee_industry_grid.csv`
- second pass -> `Data/20260812/grid_rerun/`

I have not committed anything. The pending tree is last session's work plus this one-file fix; say the word
and I'll commit it as a baseline before the grid run starts.

Two things left to you before step 2 goes:

1. **Step 1 verification.** The RUNBOOK asks for the three checks against a Stata run of
`3.build_classification_sample_v3.do`. The memo records all six numbers as matching a pandas replication, but
the `.do` file itself was last touched at 00:53 -- after the 00:51 data output. Worth confirming the file on
disk is the one that produced the data, or rerunning it.
2. **Whether step 2 runs in this session or a fresh one.** It is defensible here for the reason above; if you
would rather the orchestrator carry no memo context at all, start a new session and paste the block from
`grid_build_prompt.md`.

--- AGENT   [2026-08-12 19:01:05] ----------------------------------------
The grid is built. All 69 industries, 1,311 cells, one isolated subagent per industry.

## 1. Coverage and hit rate

**1,311 cells; 372 with jurisdiction (28.4%).** Mean 5.4 committees per industry, median 5, range 2 (Personal
Products, Health Care REITs) to 11 (Oil, Gas & Consumable Fuels).

Output: `Data/20260812/committee_industry_grid.csv`, plus the 69 per-industry files in `Data/20260812/grid/`.
All 69 passed structural validation -- 19 rows each, exact committee strings, `has_jurisdiction ? {0,1}`,
`strand` non-empty exactly where the cell is 1.

## 2. Hit rate per committee

| committee | n of 69 | | committee | n of 69 |
|---|---|---|---|---|
| energy and commerce | **64 (92.8%)** | | armed services | 19 (27.5%) |
| judiciary | 49 (71.0%) | | natural resources | 18 (26.1%) |
| transportation and infrastructure | 39 (56.5%) | | foreign affairs | 16 (23.2%) |
| homeland security | 27 (39.1%) | | intelligence (select) | 11 (15.9%) |
| oversight and government reform | 26 (37.7%) | | veterans affairs | 8 (11.6%) |
| science, space, and technology | 24 (34.8%) | | small business | 2 (2.9%) |
```

| agriculture, financial services, education & workforce | 23 each (33.3%) | | budget, rules, ethics, house administration | **0** |

3. The four predicted zeros

All four came back all-zero. 276 cells, no exceptions. No agent credited `budget`, `rules`, `ethics`, or `house administration` for any industry, though each was free to and several considered it explicitly. The closest near-miss was recorded rather than acted on: the 502010 Media agent flagged `house administration` as "the strongest candidate anywhere in the economy" -- federal election law is its remit and political advertising is a large biennial revenue line for broadcasters -- and held it at 0 because the rules that bind the broadcaster (lowest unit charge, the political file) are Communications Act, i.e. E&C. The prediction survives.

`small business` nearly joined them: 2 of 69, both where the SBA program runs through the firm rather than to it (7(a) franchise lending for hotels/restaurants; 7(a) and 504 delivered by bank lenders).

4. Two things that bear on the measure

Energy and Commerce fires for 64 of 69 industries. At 92.8% it is approaching the firm-invariant condition that got Ways and Means merged out of the judged set in the first place. The five zeros are Aerospace & Defense, Air Freight & Logistics, and the three financial industries. Every credited cell names its strand, so splitting E&C by strand costs nothing to run if you want the discrimination back.

One cell is time-varying and the grid records it as a constant. Securities and exchanges jurisdiction moved from Commerce to the new Financial Services Committee in January 2001. Three agents flagged independently -- without seeing each other -- that E&C is a **1 for cycle 2000** and 0 after, for Thrifts & Mortgage Finance, Diversified Financials, and Capital Markets. Cycle 2000 will be mis-scored for those three industries unless the join conditions on cycle.

5. The ten least-certain cells

Ranked by how load-bearing the flag is, using the agents' own words:

1. **E&C x the three financial industries** -- the 2001 transfer above. The only flag that is a fact rather than a judgement, and the only one that changes with cycle.
2. **agriculture x Oil & Gas, Capital Markets, Diversified Financials, the three utilities** -- all credited on CFTC/Commodity Exchange Act jurisdiction. The 101020 agent put the objection plainly: "this regulates their *trading*, not their *production*; a stricter reading gives 0." The utilities agents split on it. One convention would move ~6 cells.
3. **education and the workforce x Chemicals, Building Products, Construction & Engineering, Commercial Services** -- all credited on OSHA standards written *for* the industry (PSM, silica, Davis-Bacon). The 151010 agent: "exactly the trap the definition warns against... a reviewer applying the firm-invariance test more strictly would flip this to 0."
4. **armed services x Construction & Engineering** -- "rests on scale, not on a clean legal distinction... if the grid's convention is that procurement demand never counts, armed services should flip to 0." The same agent zeroed foreign affairs, veterans affairs and homeland security on identical logic, so this cell defines the demand-channel line for the whole grid.
5. **transportation and infrastructure x Construction Materials** -- the mirror image: credited as a demand channel while housing finance and MILCON were refused. "If the grid's convention is that demand channels never count, T&I should flip to 0 too."
6. **small business x Hotels, Restaurants & Leisure** -- "the Compustat firms in 253010 are large-cap chains, not small businesses; the stake runs through their franchisees rather than the firm itself."
7. **intelligence (select) x Interactive Media** -- "the only one where I credited on a rationale different from the prompt's stated one." Credited on FISA ?702 compulsion rather than on budget authorization, and live only from 2008.
8. **science, space, and technology x Biotechnology** -- "If the grid is later found to over-credit, this is the first cell to revisit." NIH, the funder that matters, sits with E&C; this rests on DOE/NIST/tech-transfer.
9. **oversight x Pharmaceuticals, Tobacco, Banks, Aerospace, Biotech** -- 26 cells credited, and several agents warned the exposure is episodic (crisis-era hearings, 2019-22 drug pricing) while the grid records it as constant across all twelve cycles.
10. **agriculture x Biotechnology = 0** -- flagged because it will look wrong: "the call rests on the *composition of the GICS bucket*, not on the word 'biotechnology' -- a reader who checks only the industry name will think this row is wrong."

Six industries (203030, 251010, 302020, 404020, 451010, 452030) had their agents killed by API limits *after* the file was written but before the report came back. Their CSVs are structurally clean and used as-is; their self-reported uncertain cells are lost and are not in the list above.

Recorded in `Guidance/_runlog.md`, with the exact per-industry prompt preserved in `Guidance/grid_subagent_prompt_template.md` so any cell can be re-run under identical conditions.

```
**Stopping here -- the grid is not joined onto the donation rows.** The second pass (5 random industries
re-run in a fresh session into `Data/20260812/grid_rerun/`) is the reproducibility statistic and is yours to
trigger.

cswap switch personal

--- AGENT   [2026-08-12 19:42:54] ----------------------------------------
Noted. Nothing is running -- Stage A finished and stopped cleanly at the report.

State on disk:
- `Data/20260812/committee_industry_grid.csv` -- 1,311 cells, validated
- `Data/20260812/grid/` -- 69 per-industry files
- `Guidance/grid_subagent_prompt_template.md` -- the exact prompt, for re-runs
- `Guidance/_runlog.md` -- Stage A entry appended

The second pass (5 random industries into `Data/20260812/grid_rerun/`) is specified to run in a **new
session**, so it shouldn't happen here -- starting it in this context would defeat the isolation the
reproducibility number depends on.

If you want something else in this session, say the word.

--- AUTHOR  [2026-08-12 19:44:01] ----------------------------------------
what's the login account?
      [action] Bash: python -c " import json,os p=os.path.expanduser('~/.claude.json')
      ↪  d=json.load(open(p,encoding='utf-8')) a=d.get('oauthAccount',{}) for k in ['emailAdd

--- AGENT   [2026-08-12 19:44:20] ----------------------------------------
Currently logged in as **devinzhang99@outlook.com** -- your personal account (org:
"devinzhang99@outlook.com's Organization", role admin). That matches the last `cswap switch personal`.

Read from `~/.claude.json` (`oauthAccount`); I only pulled the identity fields, not credentials. `/status` in
the CLI shows the same thing if you want to check it without asking me.

--- AUTHOR  [2026-08-12 19:44:35] ----------------------------------------
cswap switch personal

--- AGENT   [2026-08-12 19:44:43] ----------------------------------------
Already on personal -- `devinzhang99@outlook.com`, as of the check a moment ago. That switch is a no-op.

Nothing is running and Stage A is done. Ready when you have the next task.

--- AUTHOR  [2026-08-12 19:44:54] ----------------------------------------
cswap switch work
      [action] Bash: python -c " import json,os
      ↪  d=json.load(open(os.path.expanduser('~/.claude.json'),encoding='utf-8')) a=d.get('oauthAccount',{})
      ↪  print('emailAddress:',

--- AGENT   [2026-08-12 19:45:13] ----------------------------------------
`~/.claude.json` still reads **devinzhang99@outlook.com** (personal) after the swap. Either `cswap` hasn't
written yet, it writes somewhere else, or the change needs a Claude Code restart to take.

Worth confirming with `/status` before you rely on it -- if that also shows personal, this session is still
billing to the personal account regardless of what `cswap` reported.

Nothing running on my side either way.

--- AUTHOR  [2026-08-12 19:45:38] ----------------------------------------
cswap run personal
```

```
--- AGENT   [2026-08-12 19:45:52] ----------------------------------------
These messages are arriving as chat text, not executing as commands -- that's likely why the account never
changed. Let me run it for you.
      [action] Bash: command -v cswap || type cswap 2>/dev/null || echo "NOT FOUND on PATH"
      [action] PowerShell: $c = Get-Command cswap -ErrorAction SilentlyContinue; if ($c) { $c | Format-List
      ↪  Name, CommandType, Source, Definition } else { Write-Output "cswap: n
      [action] Bash: ls -1 ~/.claude/cswap* ~/cswap* ~/bin/cswap* ~/.local/bin/cswap* 2>/dev/null; grep -ril
      ↪  "cswap" ~/.bashrc ~/.bash_profile ~/.profile ~/.claude/setting

--- AGENT   [2026-08-12 19:46:22] ----------------------------------------
Found it -- `~/.local/bin/cswap.exe`, just not on the Bash tool's PATH. Checking what `run` does before
invoking it:
      [action] Bash: cd ~ && ./.local/bin/cswap.exe --help 2>&1 | head -40

--- AGENT   [2026-08-12 19:46:40] ----------------------------------------
`run` is scoped "this terminal only" -- so invoking it from my Bash tool would only affect that throwaway
subprocess, not your Claude Code session. Here's the actual state instead:
      [action] Bash: cd ~ && ./.local/bin/cswap.exe status 2>&1 | head -20; echo "=== LIST ===";
      ↪  ./.local/bin/cswap.exe list 2>&1 | head -25

--- AGENT   [2026-08-12 19:47:08] ----------------------------------------
That explains the failed subagents. Two things:

**The switches never took.** Account 2 `personal` (devinzfin@gmail.com) has a **dead refresh token** -- cswap
reports "re-login needed". Every `cswap switch personal` had nowhere to go, so you stayed on account 1
throughout.

**Account 1 is out of headroom.** It's at **100% of the 5-hour limit** (resets 19:40, ~3h 53m) and **91% of
the spend cap** ($18.25 / $20.00). That is exactly what killed the batch-4 and batch-10/11 subagents -- the
"session limit" and "monthly spend limit" errors were real, not transient.

Correction to what I told you earlier: cswap labels devinzhang99@outlook.com as **`work`**, not personal. I
read it off `~/.claude.json` as "personal" because that's the swap command you'd just run -- but the swap
hadn't applied. The gmail account is the one aliased `personal`.

To get onto the other account:

```
/login                 -> sign in as devinzfin@gmail.com
! cswap add            -> re-register it so cswap can switch to it
```

Then `cswap switch personal` will work. Its last-seen usage was 5% four days ago, so it has room.

Otherwise the 5h window on the current account frees up at 19:40, but the $18.25/$20 spend cap is the binding
ceiling and won't move until the monthly reset.

No work is pending -- Stage A is complete and on disk, so nothing is lost either way.

--- AGENT   [2026-08-12 20:34:05] --
Everything is staged correctly: 116 cells (69 E&C + 47 demand), v1 preserved and byte-identical to the
```

```
current grid, worklist consistent.

Two things you should know before I start, then I'll proceed:

**This is not a fresh session.** `grid_rejudge_prompt.md` says to run it in one, and bars the orchestrator
from reading a cell's previous answer before dispatching it. My context already holds much of v1 from the
Stage A batch reports. Subagent-level blindness is intact -- they receive nothing about v1 -- so the
judgements themselves stay clean; the exposure is that I know some v1 answers while dispatching. I'll
dispatch mechanically from the worklist so no v1 content can reach a prompt.

**Account headroom is thin** -- 5h window at 100%, spend at 91%. Expect agents to die partway. The design
already tolerates this: written files stay valid and I re-dispatch only what's missing.

Recording the exact prompt first, so a resume after a failure uses identical text:
      [action] Write: G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI -

cswap switch work

--- AGENT   [2026-08-12 20:43:09] ----------------------------------------
Stopped.

**Step 2b state:** 10 of 69 industries written to `Data/20260812/grid_rejudge/` (101010, 101020, 151010,
151020, 151030, 151040, 151050, 201010, 201020, 201030) -- all validated, correct committees, correct schema.
59 remaining, next up is 201040.

Nothing is corrupted and nothing needs redoing. v1 is untouched at `grid_v1/`, and
`committee_industry_grid.csv` is still byte-identical to v1 -- the substitution only happens after all 116
```

cells are written, so the grid in use is unchanged.

Early signal from the 10 done: the strict E&C standard is biting. 151020 Construction Materials and 201010 Aerospace & Defense both went 1 -> 0 on E&C; 151030, 151040, 151050, 201020 held at 1 on specifically-named strands. The demand convention has produced flips too -- 201030 Construction & Engineering picked up foreign affairs, homeland security and veterans affairs.

To resume, just say so and I'll continue from 201040 with the identical prompt (recorded at `Guidance/grid_rejudge_subagent_template.md`).

--- AUTHOR [2026-08-12 20:43:34] ----------
what's the currently login account?
[action] Bash: cd ~ && ./.local/bin/cswap.exe status 2>&1 | grep -v "newer version"

--- AGENT [2026-08-12 20:43:54] ----------
Still **Account-1 -- devinzhang99@outlook.com**, the one aliased `work`. Your `cswap switch work` was a no-op because you were already on it.

What changed since the last check: the rate windows reset (5h and 7d both back to 0%), but the **spend cap is now 97% -- $19.47 of $20.00**. About $0.53 left.

That's the binding constraint. The 59 remaining rejudge industries would exhaust it within a batch or two. Account 2 (`personal`, devinzfin@gmail.com) still shows the dead refresh token, so it can't be switched to until you `/login` as that account and run `cswap add`.

--- AUTHOR [2026-08-12 20:45:41] ----------
OK, let's continue do batch 3.

--- AGENT [2026-08-12 20:45:48] ----------
Proceeding -- batch 3 of 14: 201040, 201050, 201060, 202010, 202020.

--- AGENT [2026-08-12 20:48:57] ----------
Batch 3 done and validated. **15 of 69 industries, 32 of 116 cells.**

Results from this batch:

industry	committee	verdict	basis
201040 Electrical Equipment	energy and commerce	**1**	EPCA/EISA efficiency standards for motors, transformers, lamps
	oversight	0	procurement reach is economy-wide
201050 Industrial Conglomerates	energy and commerce	**1**	NRC licensing + EPCA + FDA devices + TSCA -- four strands, one per segment
201060 Machinery	energy and commerce	**1**	Clean Air Act **Title II** -- regulates the engine as a product, not the plant
202010 Commercial Services	armed services	0	DoD services contracts read the same for any vendor
	energy and commerce	**1**	RCRA permitting -- the waste segment's operating licence
	veterans affairs	0	VA is one customer, not a programme
202020 Professional Services	energy and commerce	**0**	FTC/privacy reaches every data holder; FCRA is Financial Services
	homeland security	0	consulting is an input to every DHS programme

The strict standard is discriminating rather than just cutting. The 201060 agent drew the sharpest line available: Clean Air Act **Title II** certifies the engine before sale and reaches only firms that build engine-powered equipment, so it survives -- while facility-side air permitting, which reaches every manufacturer, does not. That's exactly the distinction Change 2 asks for, reached independently.

```
Running tally on E&C across the 15 judged: **11 held at 1, 4 dropped to 0** (151020 Construction Materials,
201010 Aerospace & Defense, 202020 Professional Services, and -- from batch 1 -- none other). Too early to
project the final rate.

**Budget:** $19.47 / $20.00 -- 97%, unchanged from before the batch, so the meter appears to lag. The 5h
window is at 7%. Next batch (4) is 203010, 203020, 203030, 203040, 251010 -- six cells. Say the word and I'll
run it.

Step 2b is complete. All 116 cells re-judged, 69 industries, none lost.

## Headline

| | v1 | v2 |
|---|---|---|
| cells with jurisdiction | 372 / 1311 (28.4%) | **361 / 1311 (27.5%)** |
| **energy and commerce** | **64 / 69 (92.8%)** | **45 / 69 (65.2%)** |
| mean committees per industry | 5.39 | 5.23 |

**E&C: 19 of 69 flipped 1 -> 0, zero flipped the other way.** The strict standard cut just over a quarter of
its hits and left 50 untouched -- it discriminated rather than simply shaved.

**Demand: 8 of the 47 refusing zeros flipped 0 -> 1**; 39 held. The flips are Construction & Engineering
(foreign affairs, homeland security, veterans affairs), Airlines (armed services -- Civil Reserve Air Fleet),
Pharmaceuticals (armed services -- TRICARE pharmacy under 10 U.S.C. 1074g), Life Sciences Tools (armed
services + homeland security -- chem-bio detection), IT Services (veterans affairs -- VA EHR).

**No cell moved 1 -> 0 outside E&C**, as the prompt predicted. The four all-zero committees are still
all-zero. No industry was left with zero committees.

## Where the cut landed

The 19 drops cluster exactly where the standard was aimed: **finance and real estate** (Banks, Consumer
Finance, Insurance, all three real-estate codes -- E&C's contact there is FTC consumer protection or CERCLA
landowner liability, while the governing law is Financial Services); **transport** (Airlines, Marine, Road &
Rail -- T&I holds operating regulation, E&C keeps only mobile-source air rules); **hardware and retail**
(Semiconductors, Tech Hardware, Office Electronics, Specialty Retail, Distributors).

What survived is the FDA/FCC/FERC core -- E&C holds wherever it licenses the product or sets the rate:
pharma, biotech, devices, tobacco, food, telecom, broadcast, every utility.
```

The sharpest evidence the standard is doing real work rather than applying a quota: two agents, blind to each other, split the Clean Air Act the same way. Machinery **survives** on Title II, which certifies the engine as a product and reaches only firms building engine-powered equipment. Construction Materials **falls** on cement-kiln NESHAP -- facility-side air regulation shared with all heavy manufacturing. Same statute, opposite verdicts, on the distinction Change 2 asks for.

One thing worth your attention

`judiciary` is now the highest-firing committee, 49 of 69 (71%) -- ahead of E&C. Several agents credited it on patent, antitrust or bankruptcy law while noting in the same sentence that those are economy-wide, which is precisely the objection that got E&C tightened. If 93% warranted a strict standard, 71% deserves the same question before the grid is joined.

The diagnostic that motivated 2b -- the 27% of `cmte_sector_juris = 1` **rows** positive only through E&C -- is row-level and needs the join, so it belongs to RUNBOOK step 4. At grid level it can't be computed: no industry in either version is positive through E&C alone.

Files

- `Data/20260812/committee_industry_grid.csv` -- v2, 116 cells substituted, all others carried from v1
- `Data/20260812/grid_convention_diff.csv` -- one row per re-judged cell with both answers, both strands, both notes, and a `changed` flag
- `Data/20260812/grid_rejudge/` (69 files), `grid_rejudge_all.csv`
- `grid_v1/` and `committee_industry_grid_v1.csv` -- untouched
- `Guidance/grid_rejudge_subagent_template.md` -- the exact prompt; `_runlog.md` -- full entry

Stopped here -- the grid is not joined onto the donation rows. Per RUNBOOK, step 3 (the blind reproducibility rerun) comes next and needs a fresh session.

One caveat on the record: this ran in the same session that built v1, against the prompt's "fresh session" instruction. Subagent blindness held -- no v1 content reached any prompt -- but the orchestrator was not blind, and that's logged in `_runlog.md`.

--- AUTHOR [2026-08-12 21:51:02] ----------
1. Has anyone establish a committee-industry mapping that is widely used by researchers? 2. What's the relationship between grid and grid_v1 folders? Also what's the relationship between committee_industry_grid.csv and committee_industry_grid_v1.csv? 3. What should I do next?

--- AGENT [2026-08-12 21:51:44] ----------
Let me verify the file facts before answering (2).

--- AGENT [2026-08-12 21:52:30] ----------
1. Is there a canonical committee x industry mapping?

Not that I know of -- and I have not verified this with a literature search, so treat it as a prior to check, not a finding. Flagging that explicitly because the project standard is that citations get verified before they enter a draft.

What I believe exists, and what it isn't:

Infrastructure	What it maps	Why it isn't this
Policy Agendas / Comparative Agendas Project (Baumgartner & Jones); **Congressional Bills Project** (Adler & Wilkerson)	bills and hearings -> policy topic codes, with referral committee	committee -> *policy topic*, not committee -> *industry*. Widely used, and the closest thing to a standard.
Lobbying Disclosure Act issue codes (79 general areas)	firm's lobbying report -> issue area, and which chambers/agencies were lobbied	firm-declared, not a jurisdiction map. But see below.
OpenSecrets/CRP catcodes	donor -> industry	donor side only.
Jurisdiction scholarship -- King, *Turf Wars* (1997); Adler, *Why Congressional Reforms Fail* (2002)	how jurisdictions form and move	descriptive/theoretical, no firm-facing crosswalk.

The pattern in the finance papers that link firms to committees -- Cooper, Gulen & Ovtchinnikov (JF 2010); Akey (RFS 2015); Bertrand, Bombardini & Trebbi (AER 2014) -- is, as far as I recall, ad hoc: researcher judgment on a handful of committees, or the firm's own lobbying disclosures. **All of those citations need checking before they go anywhere near a draft.**

Two consequences, and the second is the useful one:

- **The grid is itself a contribution** if no public crosswalk exists. 1,311 cells, every one with a named strand, small enough to publish whole.
- **There is no external benchmark to validate it against -- but there is one you could build.** LDA reports name the specific committees a firm lobbied. That is revealed-preference data on which committees a firm thinks have jurisdiction over it, generated by the firms themselves, independent of your grid. Validating `cmte_sector_juris` against lobbying-declared committee contact is exactly the external-validation step `gate-measure` asks for, and it's the strongest defence available against "this is just a nonlinear re-expression of the covariates."

2. The folders and files

Verified just now, not recalled:

```
grid/          69 files, 19 rows each   <- Stage A output (v1), the original
grid_v1/       69 files, 19 rows each   <- byte-identical copy of grid/, all 69 files
grid_rejudge/  69 files, 1-5 rows each  <- step 2b output, ONLY the 116 re-judged cells
```

`grid/` and `grid_v1/` are **the same thing** -- you made `grid_v1/` as the backup before 2b, and nothing has written to `grid/` since. It's now redundant. `grid_rejudge/` is a different shape: it has no `gics6_name` column and holds only the cells on the worklist, so it is a patch, not a grid.

```
committee_industry_grid_v1.csv   1311 rows  <- concat(grid_v1), the v1 grid
committee_industry_grid.csv      1311 rows  <- v2 = v1 with the 116 cells substituted
grid_convention_diff.csv          116 rows  <- both answers side by side, with a `changed` flag
```

`committee_industry_grid.csv` is the live grid and the one step 4 should join. It is *not* a concatenation of `grid_rejudge/` -- 1,195 of its cells come straight from v1.

One housekeeping suggestion: `grid/` now duplicates `grid_v1/` and will be confusing in six months. Delete it or rename it `grid_v1_dup/`. I haven't touched it.

3. What to do next

Settle judiciary before running step 3. That's your own logic from the 2b note -- "measuring the reproducibility of a grid you are about to revise wastes the session" -- and it applies again. Judiciary now fires for **49 of 69 (71%)**, higher than E&C's post-tightening 65%, and several agents credited it while writing in their own notes that patent, antitrust and bankruptcy law are economy-wide. That is the identical defect that triggered 2b, one committee over. Either tighten it the same way (a step 2c on ~49 cells) or write down why 71% is acceptable for judiciary when 93% wasn't for E&C. A referee will ask.

Then, in order:

1. **Step 3** -- blind reproducibility rerun, 5 random industries, fresh session. Genuinely fresh this time: this session is contaminated for that purpose in a way it wasn't for 2b, because reproducibility is the number the paper reports.
2. **Step 4** -- the join. This is also where the diagnostic that motivated 2b finally gets computed: the share of `cmte_sector_juris = 1` **rows** positive only through E&C, 27% on v1. That number tells you whether the tightening actually worked at the row level; the grid alone can't say.
3. Steps 5-7.

On sequencing against your budget: you're at $19.47/$20.00. Step 4 is pure code and cheap. Steps 3 and any 2c are subagent-heavy. If the cap binds before the gmail account is re-registered, run step 4 first -- it costs almost nothing and produces the diagnostic that tells you whether 2b succeeded, which is the thing you'd most want to know before spending on 2c or step 3.

--- AUTHOR [2026-08-12 22:09:10] --
1. If we want to make grid itself a contribution, our grid needs to be solid. I want the grid to be part of the contrbution of the paper (i.e., we provide one of the first LLM searched and verified grid between committees and industries). To make this happen, we should refer and consider LDA reports, right? Or you think we can have a separate verification step to check our grid? 2. I do have a question on judiciary related grid because I also don't know how much I can say judiciary committee has oversight on one industry? Or will it make more sense if we don't map judiciary committee to most industries?

--- AGENT   [2026-08-12 22:11:00] --
Two good questions, and the first one has a trap in it. Let me take them in order.

```
## 1. LDA: validation instrument, never a construction input

**If you build the grid from lobbying data, you destroy the contribution and the research design at the same time.** Lobbying is endogenous to exactly what donations are endogenous to -- firms lobby the committees whose members they donate to, for the same reasons. A grid built from LDA would turn the second half of the paper into "lobbying predicts donations," which is close to tautological. Keep LDA strictly on the validation side and the grid stays an independent construct.

**A correction to what I said last turn.** I claimed LDA reports "name the specific committees a firm lobbied." That was too confident. My recollection of the LD-2 form is that the structured field lists **chambers and agencies** -- "U.S. House of Representatives," "EPA" -- and that committees appear only inconsistently, in the free-text specific-issues description. If that's right, committee-level validation from LDA needs text parsing with unknown recall. Verify the form's actual fields before building anything on it.

Three validation instruments, ranked by how much I'd trust the plumbing:

| instrument | chain | my confidence in feasibility |
|---|---|---|
| **Bill referrals via lobbying** | LD-2 specific-issues text names bill numbers -> bill -> committee of referral (mechanical, congress.gov / Congressional Bills Project) | highest -- the referral step is public and exact; only the bill-number extraction is fuzzy |
| **Hearing witnesses** | firm testifies before committee c -> revealed jurisdiction | high; witness lists are structured, but sparse -- big firms only |
| **LDA agency/chamber field** | firm lobbied agency A -> A's authorizing committee | medium; agency->committee is clean, but it validates a coarser object |

**The specification matters more than the instrument.** Powerful committees attract lobbying regardless of jurisdiction, so raw agreement will flatter you. The test that means something is whether the grid predicts firm-committee contact *net of committee and industry fixed effects* -- same structure as your redundancy gate. If `grid[industry, committee] = 1` survives both sets of FE in predicting revealed contact, the grid carries information that neither "this is a big committee" nor "this is a lobbying-heavy industry" explains.

**Also do the cheap thing.** Have a human blind-code a random ~100 cells and report Cohen's kappa against the LLM grid. For a top-3 finance referee that is the expected validation, it costs a few hours, and no amount of LDA cleverness substitutes for it.

**One framing correction, because it affects what you can claim.** You wrote "LLM searched and verified." The agents overwhelmingly did *not* search -- the large majority explicitly reported judging from institutional knowledge with no search. Claiming "searched" would be inaccurate and a referee could check it against your own logs. What you can claim, all of it true and checkable:

> a committee x industry jurisdiction grid generated under enforced per-cell isolation, in which every credited cell names the specific statutory strand, with measured reproducibility and measured convention-sensitivity.

That is a stronger claim than "searched," because the isolation design and the two numbers are the unusual part.

## 2. Judiciary -- the structural diagnosis

Your instinct is right, and there's a principled way to say why. **House Judiciary's jurisdiction is organized by legal instrument, not by economic sector.** Antitrust, bankruptcy, patents, immigration, criminal law -- each reaches every firm in the economy, with the *intensity* varying by industry but the *coverage* not varying at all.

That is precisely the argument that removed Ways and Means from the judged set: the link is real, but it's the same for every firm, which makes it untestable. Judiciary is Ways and Means in structure.

Three treatments:

**A. Move judiciary out of the judged set** into a mechanical horizontal flag beside W&M and Appropriations. Clean and consistent. Cost: you throw away the genuinely sectoral pockets -- Hatch-Waxman for pharma is not a generic patent interest, it's the industry's central statute; likewise PLCAA for firearms, ?1110 aircraft equipment for airlines, the McCarran-Ferguson antitrust exemption for insurance, the railroad rate-agreement immunity.

**B. Tighten it the way you tightened E&C** -- credit judiciary only where Congress wrote a statute *for this industry*, not where a general body of law happens to bite hard. That would cut it from 49 to roughly 10-15
```

and preserve the sharp cells.

C. Leave it and disclose. Weakest; a referee finds it before you do.

I'd take B -- but not for judiciary alone, and this is the part worth thinking about before you spend anything.

The real issue is that the standard is currently committee-specific

Right now E&C is held to a strict standard and the other eighteen aren't. Tightening judiciary next makes it two, and invites the obvious question: why those two? Fitting the standard to the committee, one committee at a time, is the thing referees smell.

The defensible version states **one rule** and applies it to every structurally horizontal committee:

> Credit a committee only where its remit reaches this industry through a **sectoral** instrument. Where the instrument is horizontal -- applying to all firms, with only the intensity varying -- the cell is 0, however large the stake.

Sorting your 19 by structure:

- **Horizontal** (instrument-based, reaches everyone): judiciary 49, homeland security 29, oversight 26, science 24, education & workforce 23 -- currently **151 cells at 1**
- **Sectoral** (already discriminating): agriculture, armed services, E&C, financial services, natural resources, T&I, veterans affairs, foreign affairs, intelligence
- **Already self-limiting**: small business 2; budget / rules / ethics / house administration 0

So the bounded job is: **re-judge the 151 currently-1 cells of the five horizontal committees under one stated standard.** Comparable in size to 2b's 116, it never needs to touch a 0 (tightening only cuts), and it ends with a single rule you can state in one sentence in the paper rather than a sequence of ad-hoc fixes.

The diagnostic that tells you it worked: judiciary should land in the same 25-40% band the sectoral committees occupy. If it lands at 5% or stays at 65%, the standard is mis-specified.

What I'd do, in order

1. **Decide A vs. B for judiciary, and whether to do it as a one-committee fix or the five-committee uniform standard.** Your call -- it's a scope decision with a real cost difference. If you want my recommendation: the uniform version, because the one-sentence rule is worth more to a referee than the saved compute.
2. **Step 4, the join** -- it's pure code, nearly free, and it produces the row-level diagnostic (the 27% E&C-only share) that tells you whether 2b actually worked. Run it before spending on anything else, regardless of what you decide in (1). It's reversible; the grid can be revised and rejoined.
3. **Step 3 reproducibility, fresh session** -- after the grid is final, not before.
4. **Validation design** -- LDA/bills/hearings plus the human blind-code. This is a separate workstream and shouldn't block the pipeline.

Tell me which way you want (1) to go and I'll write the prompt for it.

--- AUTHOR [2026-08-12 22:21:50] ----------
1. I'm Ok with "a committee x industry jurisdiction grid generated under enforced per-cell isolation, in which every credited cell names the specific statutory strand, with measured reproducibility and measured convention-sensitivity." and think Bill referrals via lobbying can be a good instructment for us to check our grid later. Do we need to build the Bill referrals
via lobbying sample that will allow us to check the grid, or is it available somewhere? 2. I like your sorting structures for the committee and agree that we should adopt the same standard to judiciary as those to E&C. One think we need to confirm: what committess should go to the Horizontal group? Do homeland security and science also go there? I think after we confirm those should go to the horizontal ones, we can rejudge the grid for those committees and make our grid tightened.

--- AGENT [2026-08-12 22:22:49] ----------
Let me check two things before answering -- whether lobbying data already exists in your shared folder, and what the credited strands actually rest on.

      ↪  Political Donation Motive" && python -c " import pandas as pd,

--- AGENT   [2026-08-12 22:25:26] ----------------------------------------
Both questions have better answers than I gave last turn, because two relevant assets are already on your
disk.

## 1. The bill-referral instrument -- mostly built already

**`1.Common Dataset/Politics/2.Complied Data by Others/2000-2018 firm-pac donation-lobbying-tariff bills/`**
holds the Dataverse replication package for **Kim, Stuckatz & Freiheyt (2025, *Journal of Politics*),
"Systemic and Sequential Links between Campaign Donations and Lobbying"** -- 3 GB, already downloaded, with
`compustat_1954_2018_deduped.csv`, a firm-level donation-lobbying panel, and GovTrack linkage. The estimation
objects carry variable names `CommLob`, `SpLob`, `CoSpLob`, `AnyDon`, `CeoDon`.

**`CommLob` is very likely committee-level lobbying contact.** If so, the instrument I described is
essentially done: firm x committee revealed contact, Compustat-linked, 2000-2018, covering your window minus
the last two cycles. **Read `0_Codebook.pdf` before anything else** -- that one file decides whether this is
a week of work or an afternoon.

Two flags on it:

- **Positioning, not data.** KSF (2025) is *very* close to your topic -- firm-level donations and lobbying,
same period, same identifiers. Your paper has to position against it explicitly, and the distinction is clean
(they study the donation<->lobbying link; you infer the *motive* behind the donation), but it needs to be
made in the introduction rather than discovered by a referee. This belongs in the RAP now, not later.
- Coverage is selected: only lobbying firms appear. Most Compustat firms never file. Validation will run on a
subsample, and you report that.

Keep the direction of use strict, as before: **LDA validates the grid; it never builds it.** Build from
lobbying and "committee jurisdiction predicts donations" collapses into "lobbying predicts donations."

### The other asset, and a correction

**`1.Common Dataset/Politics/1.GICS_cmte Crosswalk/`** already contains a GICS4 x House committee crosswalk
(Nov 2025), 41 rows over 25 industry groups, with a reasoning file and a committee-code lookup.

**It is not a human benchmark.** The reasoning column reads as single-pass LLM output -- prose lists with
parenthetical justifications -- and it credits Ways and Means, which this project deliberately excludes. Do
not present it as external validation; a referee who opens it will see the same thing.

What it *is* worth: a comparison of **elicitation design**. One-shot, all industries in one context, GICS4
versus isolated, per-cell, GICS6. Agreement between the two is a genuine and publishable statistic about
whether the isolation protocol changes answers -- which is the methodological claim your grid rests on.

Worth noting in passing: that crosswalk averages **1.6 committees per industry group**; your v2 grid averages
**5.2 per industry**. Granularity explains part of it, not all. That gap points the same way as the
tightening.

Genuine external validation still needs the KSF instrument, or a human blind-coding a random ~100 cells. Do
the human one regardless; it's cheap and it's what referees expect.

## 2. Which committees are horizontal -- settled with evidence

I classified every credited strand in v2 by whether it names a horizontal legal instrument (antitrust,
bankruptcy, patents, immigration, OSHA/ERISA/labor, federal procurement, cyber/critical infrastructure,
customs/cargo, generic R&D):

| committee | cells at 1 | share resting on a horizontal instrument |
|---|---|---|
| judiciary | 49 | **98%** |
| science, space, and technology | 24 | **88%** |
| oversight and government reform | 26 | **77%** |
| homeland security | 29 | **76%** |
```

| education and the workforce | 23 | **74%** |
| **transportation and infrastructure** | 39 | **8%** |

Yes to homeland security and science -- both belong. Homeland security's 29 credits are dominated by two horizontal strands: CISA critical-infrastructure cybersecurity (banks, software, IT services, telecom, all four utilities -- the designated-sector list covers essentially everyone) and CBP/C-TPAT cargo security (every importer). What should survive is the genuinely sectoral remainder: CFATS for chemicals and gas, TSA aviation for airlines, MTSA/port security for marine, border construction, DHS detection procurement.

No to transportation and infrastructure, despite its high 39/69. Its credits are FAA, FRA, FMCSA, Coast Guard, the highway program -- modal regulation defined by what the industry operates. It's high because it's genuinely broad, not because it's loose. That saves 39 cells and, more importantly, it's evidence that the test discriminates rather than just cutting whatever is large.

So: five committees, 151 cells. judiciary 49 + homeland security 29 + oversight 26 + science 24 + education & workforce 23.

The standard, written once

The concept that generalizes your E&C test is the **instrument**, not the committee:

> Credit a committee only where its remit reaches this industry through a **sectoral instrument** -- a statute, programme or regulatory regime whose scope is defined by what this industry makes, sells or operates. Where the instrument is **horizontal** -- defined by a legal function (antitrust, bankruptcy, intellectual property, immigration, workplace safety, employee benefits, federal procurement, cybersecurity, customs, generic R&D authorisation) and applying to firms in every sector with only the intensity varying -- the cell is 0, however large the stake.

That one sentence covers E&C's strict standard as a special case, so the paper states a single rule rather than a sequence of fixes.

The test keeps real content. Cells that should survive: Hatch-Waxman and the Controlled Substances Act (pharma), PLCAA (firearms), ?1110 aircraft equipment (airlines), the McCarran-Ferguson exemption (insurance), railroad rate-agreement immunity, DMCA ?512 (platforms) under judiciary; MSHA (mining) and HEA Title IV (for-profit education) under education & workforce; the Postal Service (publishers, direct mail, parcel) under oversight; NASA (aerospace) and sector-specific NIST programmes under science.

Diagnostic that it worked: judiciary should land near the 10-25/69 band, not near 49 and not near 2.

Say the word and I'll build the worklist and write the step-2c prompt in the same form as 2b -- one isolated subagent per industry, only the currently-1 cells, `grid_v2/` preserved before anything is overwritten.

--- AUTHOR [2026-08-12 22:34:59] ----------
1. You can read 0_Codebook.pd and tell me if "Systemic and Sequential Links between Campaign Donations and Lobbying" gives what we need. We don't have to use LDA. I think the key point is that we should people our grid is solid and has been checked with other samples/methods. 2. I like this concept "Credit a committee only where its remit reaches this industry through a sectoral instrument -- a statute, programme or regulatory
  # regime whose scope is defined by what this industry makes, sells or operates. Where the instrument is horizontal -- defined by a
  # legal function (antitrust, bankruptcy, intellectual property, immigration, workplace safety, employee benefits, federal
  # procurement, cybersecurity, customs, generic R&D authorisation) and applying to firms in every sector with only the intensity
  # varying -- the cell is 0, however large the stake.", so does it mean the v3 columns/category, we should replace "cmte_wm_approp" or "cmte_other" with "cmte_horizontal" and it would be better to separate donations to candidates in an industry specific committee or in a functional committee? Should we separate "cmte_wm_approp" from these two types of committes or not?

--- AGENT [2026-08-12 22:35:45] ----------
Reading the codebook.
      [action] Read: G:\OneDrive - The Pennsylvania State University\PhD research projects\1.Common
      ↪ Dataset\Politics\2.Complied Data by Others\2000-2018 firm-pac donation-
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/1.Common
      ↪ Dataset/Politics/2.Complied Data by Others/2000-2018 firm-pac donat

--- AGENT [2026-08-12 22:36:54] ----------
Read it. Short answer: **yes, it gives you what you need, and better than LDA would.**

1. Kim, Stuckatz & Wolters -- the instrument is already built

The codebook names the paper as **Kim, In Song, Jan Stuckatz, and Lukas Wolters, "Systemic and Sequential Links between Campaign Donations and Lobbying," *Journal of Politics*** (listed as 2024 forthcoming). Note your local filename says "Freiheyt" -- the codebook says **Wolters**. Verify before citing; one of the two is wrong.

`d_final_20210127.RData` is firm-politician level, 2000-2018, and carries exactly the fields the validation needs:

field	codebook definition
`gvkey`	Compustat firm ID
`candidate_id`	**FEC candidate ID**
`bills`	bills related to politician lobbied by firm
`committees`	**committees for bills in "bills"**
`is.committee`	politician is committee member for a bill in "bills"
`don_pac`, `don_tot`	donations, by type

And `don_lob_all_ind_20210203.rds` gives a firm-legislator-year panel with `lob_comm_bin` -- "firm lobbied bill related to committee membership of legislator."

Three things make this better than parsing LDA yourself:

1. **The keys are already yours.** `gvkey` and FEC `candidate_id` are the two identifiers in your trial sample. You join directly -- no NAICS<->GICS crosswalk, no name matching.
2. **The chain is mechanical, not textual.** It runs firm -> lobbied bill -> bill's committee of referral. Bill referral is a matter of record, so the noisy step (extracting bill numbers from lobbying text) has already been done and peer-reviewed.
3. **It's revealed preference from the firm.** The grid says "committee *c* has jurisdiction over industry *i*." KSW says "firms in industry *i* actually spent money lobbying bills in committee *c*." Those are genuinely independent, which is what validation requires.

The test to run -- and the specification matters more than the data: regress firm-committee lobbying contact on `grid[industry, committee]` with **industry and committee fixed effects**. Raw agreement will flatter you, because big committees attract lobbying regardless of jurisdiction. If the grid survives both sets of FE, it carries information that neither "E&C is a big committee" nor "pharma lobbies a lot" explains.

Limits to state up front: coverage is 2000-2018, so 10 of your 12 cycles; only lobbying firms appear, so it validates on a selected subsample; and I have not opened the 3 GB archive, so how densely `committees` is populated is unverified. Worth checking before you build on it.

Combine it with a human blind-code of ~100 cells and you can write the sentence you want -- the grid has been checked against an independent revealed-preference source *and* against human coding.

2. The taxonomy question -- and there's a defect in the current design

Your instinct is right, but the conclusion runs the other way from "rename `cmte_wm_approp` to `cmte_horizontal`."

A horizontal-committee flag is firm-invariant by construction, so it cannot be a motive.

That's the whole point of the standard you just adopted. `cmte_sector_juris` varies *within candidate, across firms* -- the same member is a 1 for a pharma donor and a 0 for a bank. That within-candidate variation is what makes it a measure of why *this* firm gave to *this* candidate. A horizontal flag has none of it: if Judiciary has an antitrust claim on one firm, it has the same claim on all of them. It measures the candidate's committee portfolio, not the firm-candidate match.

This exposes a defect already in v3. The derived `committee = cmte_sector_juris | cmte_wm_approp` mixes a firm-varying measure with a firm-invariant one. Every W&M member becomes a "committee motive" for every firm, which mechanically dilutes exactly the discriminating power the grid exists to create. Under the new standard that union is not defensible.

What I'd do

Motive set -- firm-varying only:
`geography`, `cmte_sector_juris`, `social_tie`, `other`. Redefine `committee` as `= cmte_sector_juris`, or drop the derived variable.

Covariate block -- firm-invariant candidate characteristics, alongside `cand_ici`, `cand_power_l1`:
- `cmte_wm` -- tax and tariff jurisdiction
- `cmte_approp` -- discretionary funding

- `cmte_horizontal` -- the five functional committees (judiciary, education & workforce, oversight, homeland security, science)

Keep those three separate rather than merging. Three reasons: tax is the most-studied channel in this literature and a referee will want it visible on its own; W&M/Appropriations are *money* committees while judiciary/labor are *rule* committees, which are different theoretical channels; and Appropriations has a known unresolvable problem already in your runlog -- the sample records membership without subcommittee, so defence versus labor-HHS can't be distinguished. Lumping that into a clean composite hides a data limitation you've already documented.

Your second instinct is a result, not a label

"Separate donations to candidates on industry-specific versus functional committees" -- that's the paper's central test, and it belongs in the analysis rather than the taxonomy:

> Does sectoral jurisdiction predict donations *beyond* membership on functional committees, candidate power, and incumbency?

That is the redundancy gate in sharper form, and it's a better version of it, because "functional committee membership" is a much harder control than the mechanical proxies you were going to test against. If `cmte_sector_juris` survives it, the grid has earned its place.

This is a taxonomy change, so by project convention it goes in `taxonomy_decisions.md` -- either as a v3 amendment or v4, your call on which.

Three things are now queued: the step-2c re-judge prompt (151 cells, five committees), the taxonomy amendment, and the KSW validation build. Tell me which to write first -- I'd do 2c, since the grid should be final before anything validates against it.

--- AUTHOR [2026-08-12 22:46:18] ----------
1. I agree with most of what you said in the last run. 2. One question left: what committees should be classified as horizontal-committee? Would the horizontal-committee be different for firms in different industries? I feel there is cost and gain tradeoff here. 3. We're currently still doing v3 taxonomy, so we should update v3. 4. "firms in industry
  i actually spent money lobbying bills in committee c." is something we can use to check our grid. Do we need to create such a sample now, which will used to compare with our grid later after we finalize our grid?

--- AGENT [2026-08-12 22:47:10] ----------
Let me answer (2) with evidence rather than my judgment -- the same diagnostic across all 19 committees.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪ Political Donation Motive" && python -c " import pandas as pd v

--- AGENT [2026-08-12 22:48:05] ----------
The diagnostic changed my answer. **I missed foreign affairs -- it's 94% horizontal, higher than four of the five I proposed.**

2. Which committees, and is it industry-dependent?

committee	cells at 1	horizontal-instrument share	
judiciary	49	98%	**include**
foreign affairs	17	**94%**	**include -- I missed this**
science, space, and technology	24	88%	**include**
oversight and government reform	26	77%	**include**
homeland security	29	76%	**include**
education and the workforce	23	74%	**include**
armed services	22	50%	exclude -- see below
intelligence (select)	11	45%	exclude -- see below
agriculture	23	30%	optional targeted fix
financial services	23	26%	optional targeted fix
T&I / E&C / natural resources / small business	39/45/18/2	<=8%	leave

Foreign affairs rests almost entirely on export controls, dual-use licensing and sanctions -- which reach every exporter. Your own agents flagged it: the Machinery agent wrote that export controls are "close to invariant across tradable-goods industries." Same defect as judiciary, and I should have caught it before proposing a list.

Armed services and intelligence are false positives of my own diagnostic. Their flags come from the word

"procurement," which under the demand convention you adopted in 2b is now a *legitimate* sectoral basis. Exclude them; spot-check rather than re-judge.

Agriculture (CFTC/derivatives) and financial services (Ex-Im/securities) are below threshold but have identifiable horizontal pockets -- 7 and 6 cells respectively. Cheap to fold in as a targeted 13-cell addendum rather than a full re-judge of 46.

So: **six committees, 168 cells**, or 181 with the addendum.

Is "horizontal" industry-dependent? Yes -- and that resolves your tradeoff

This is the sharpest thing in your question. Judiciary is horizontal for a utility and **sectoral for pharma** (Hatch-Waxman is written for that industry alone). Education & workforce is horizontal for a bank and **sectoral for coal** (MSHA covers mines only) and **for-profit education** (HEA Title IV). Homeland security is horizontal for software and **sectoral for chemicals** (CFATS).

So there are two different objects, and they need different treatment:

- **`cmte_sector_juris` is cell-level.** The standard already handles this correctly -- it asks whether *this* committee reaches *this* industry through a sectoral instrument. After 2c, judiciary survives for pharma and firearms and dies for utilities. No committee-level list is needed or wanted here.
- **`cmte_horizontal` as a covariate is committee-level**, and it *has* to be, because being firm-invariant is the entire point of a control.

And the cost/benefit resolves itself once you notice this: in the gate specification, **candidate x cycle fixed effects absorb every firm-invariant candidate characteristic automatically** -- W&M, Appropriations, all horizontal committees, power, incumbency, party. `cmte_sector_juris` is then identified purely off the fact that the *same candidate* is a 1 for some donor industries and a 0 for others. That is the cleanest possible version of the redundancy gate, and it means a hand-built horizontal list is a descriptive convenience, not an identification requirement.

So spend on cell-level accuracy (2c) and don't over-engineer the committee-level label. A crude `cmte_horizontal` for descriptive tables is fine; the regression doesn't lean on it.

3. Update v3 -- clean, and cheap right now

Nothing downstream has been produced yet: steps 5-7 haven't run, so no labels exist under the current derivation. `cmte_wm_approp` stays in the file as a supplied column; it just stops entering `committee` and `n_motives`. That's a documentation and derivation change, not a data rebuild.

Edits needed: `taxonomy_decisions.md` (the sectoral/horizontal standard, plus the reasoning for demoting W&M/Approps out of the motive set), `classification_prompt_v3.md` ?4-5 (the standard, the revised `committee` definition), and `run_procedure.md` ?2 (derivations).

4. Build the KSW sample now -- but do not look at the comparison

Build now, for three reasons: it doesn't depend on the grid, it's code-only and nearly free against your $19.47 cap, and having it ready means the comparison is one script when the grid freezes.

With one discipline, which matters more than the timing: build the firm x committee lobbying object, write it to disk, and **do not compute agreement with the grid until the grid is final.** If you see the comparison first, any subsequent grid revision is tuning to the validation set and the validation is worthless. The 2c subagents never see it either -- that part is safe by construction, since they're isolated.

State that firewall in `_runlog.md` when you build it. It's the closest thing to pre-registration available here, and it's exactly what a referee will want to know you did.

One dependency to check: the firm-politician file is `.RData` and the panel is `.rds`, so you need R or `pyreadr`. The only plain CSV in there is Senate-only, which doesn't serve a House sample.

Order I'd go: **2c prompt -> v3 taxonomy update -> KSW build.** The grid should be frozen before anything else references it.

Shall I write the 2c prompt and worklist? I'd build it for the six committees at 168 cells, with the 13-cell agriculture/financial-services addendum flagged separately so you can take it or leave it.

--- AUTHOR [2026-08-12 22:58:59] --
I agree with your argument for 2 in the last run. But it would require LLMs to do an even more careful works

for classification because cmte_sector_juris and cmte_horizontal are gics6 specific, right?

--- AGENT [2026-08-12 22:59:57] ----------
Half right, and the half that isn't is the important one.

`cmte_horizontal` is deliberately *not* gics6-specific

That's what makes it a valid control. If it varied by industry it would no longer be firm-invariant, and it would stop absorbing generic access value -- it would start competing with `cmte_sector_juris` for the same variation.

As a covariate it needs **zero LLM judgment**. It's a lookup against a six-committee list: does the candidate sit on judiciary, foreign affairs, science, oversight, homeland security, or education & workforce? Mechanical, like `cmte_wm_approp`.

So only **one** field needs cell-level judgment -- `cmte_sector_juris` -- and that's exactly the 2c job already scoped at 168 cells. The design doesn't add a second judgment burden.

But there *is* a gics6-specific version worth having, and it makes the job easier

Right now you force every cell into a binary. Look at where your v1 agents struggled -- it was always the same shape:

> "OSHA process safety management is written *about* chemical processes, not about employers generally... a reviewer applying the firm-invariance test more strictly would flip this to 0."

The agent could see the cell clearly. What it couldn't do was express what it saw, because the only options were 1 and 0. That forced binary is what produced the inconsistency you're now fixing.

Give it three values instead:

`reach`	meaning	`cmte_sector_juris`
2	committee reaches this industry through a **sectoral** instrument	1
1	committee reaches this industry, but only through a **horizontal** instrument	0
0	committee does not reach this industry at all	0

with `instrument` naming the statute or programme for both 2 and 1.

Three things follow. The agent stops being forced to distort a real observation. The binary the paper uses is **derived, not judged** -- `cmte_sector_juris = (reach == 2)` -- so the measure is mechanical once the coding exists. And the published grid gets much better: a referee can see that chemicals x education & workforce was *considered*, that OSHA PSM was the instrument, and that it was classed horizontal rather than silently zeroed. That distinction between "we looked and rejected it" and "we never saw it" is worth a lot in an appendix.

Marginal cost in 2c: near zero. You're re-judging those 168 cells regardless; asking for a three-way code instead of a binary adds nothing per cell.

One asymmetry to disclose. The ~950 cells the first pass rejected outright would stay at `reach = 0` without being sub-classified, so some true "horizontal reach" cells sit unmarked among them. Recording that honestly -- "the horizontal category is coded only where an earlier pass credited the cell" -- is cheaper than re-judging 1,311 cells and costs you nothing analytically, since both 1 and 0 map to `cmte_sector_juris = 0`.

Does the standard ask more of the model than it can deliver?

That's the real worry behind your question, and I think the answer is no -- it asks for *less* interpretation, not more.

v1 gave the agents "jurisdiction over this firm's business," which is a concept with no decision rule attached. The new standard gives them a test they can actually run: **is the instrument's scope defined by what this industry makes, sells or operates?** That is answerable from the statute's own coverage language.

The 2b output supports this. The sharpest example: two agents, blind to each other, split the Clean Air Act on exactly the right seam -- Machinery survived on **Title II**, which certifies the engine as a product and reaches only firms building engine-powered equipment, while Construction Materials fell on **kiln NESHAP**, facility-side regulation shared with all heavy manufacturing. Neither was told that distinction. They derived it from the standard. That is what a well-specified rule looks like in operation.

And you don't have to take my word for it, which is the point of the design: **step 3 measures it.** If the standard is too subtle for consistent application, independent reruns will disagree and the reproducibility statistic will say so. That number is the check on exactly this concern, and it's already in the pipeline.

If you want the three-way code, I'll build 2c that way: `reach`, `instrument`, `note`, with `has_jurisdiction` derived on assembly so the output stays a drop-in replacement for the current grid column. Six committees, 168 cells, agriculture/financial-services addendum flagged separately.

Say go and I'll write the worklist and the prompt.

--- AUTHOR [2026-08-12 22:59:57] ----------
which also means we need to write better promots to guide LLMs when it does the classification works

--- AGENT [2026-08-12 23:00:41] ----------
Yes -- and this session produced unusually good evidence about *what* makes them better, because you can now audit 361 credited cells against the prompt that produced them.

What demonstrably worked:

- **A test beats a definition.** v1 said "jurisdiction over this firm's business" -- a concept with no decision rule. v2 said "is the instrument's scope defined by what this industry makes, sells or operates" -- something answerable from the statute's coverage language. The 19 E&C flips came from that change alone.
- **A falsification test beats a positive one.** "Would a firm in an unrelated industry describe the same stake in the same words?" appeared verbatim in agent after agent, doing the actual discriminating. It's easier to run than "is this principal?"
- **Worked examples carry more than rules.** Change 1's three examples -- shipbuilder, launch provider, hospital builder -- got cited back by name and produced 8 clean flips.
- **The evidence field is what made everything else possible.** Requiring `strand` in v1 is the only reason I could classify 361 cells as horizontal or sectoral this afternoon and find the foreign-affairs problem. That requirement was written for transparency and paid off as *auditability* two versions later. Always make the model write down what the answer rests on.
- **Asking for the marginal calls.** "State which convention decided it and how close" is how the systematic problems surfaced. The agents flagged export controls as firm-invariant themselves, before I had a diagnostic.

And one gap that is still open -- it will bite 2c if you don't fix it.

The prompt never says what to do when a GICS6 code spans genuinely different businesses, and the agents split on it without guidance:

- 252010 Household Durables -- credited on appliances; agent noted homebuilders "do not load on E&C"
- 252020 Leisure Products -- credited on toys/bikes; firearms sit outside CPSC entirely
- 302010 Beverages -- credited on soft drinks; brewers and distillers are TTB, not FDA
- 452030 Electronic Equipment -- credited on own-brand devices; "contract manufacturers carry little of this exposure"
- 601050 Health Care REITs -- credited on skilled nursing; "weakest for private-pay senior housing"

versus the opposite call on identical logic:

- 253020 Diversified Consumer Services -- **declined** the FTC Funeral Rule because it "covers a handful of firms in one sub-slice"

Same situation, opposite resolutions, and nothing in the prompt distinguishes them. That is a documented, recurring inconsistency source, and it's fixable in one sentence.

My recommendation: **credit when the instrument reaches a substantial named segment, and require the segment to be named in a new field.** Not "modal firm," which throws away real jurisdiction, and not "most firms," which would have zeroed pharmaceuticals-adjacent cells across the grid. Naming the segment keeps the cell auditable and lets you later restrict to cells that cover the whole industry if a referee pushes.

So the 2c schema becomes: `reach` (2/1/0), `instrument`, **`segment`**, `note` -- with `has_jurisdiction = (reach == 2)` derived on assembly.

These lessons transfer to step 5 as well, which hasn't run. `social_tie` and `other` are the two fields most exposed to exactly the failure the strand requirement fixes -- `other` in particular is defined as "a specific, nameable reason," which is a concept, not a test.

Want me to write 2c with the three-way code and the segment field, and fold the heterogeneity rule into the v3 prompt update at the same time?

--- AUTHOR [2026-08-12 23:09:40] ----------
1. So "judiciary, foreign affairs, science, oversight, homeland security, or education & workforc" will be cmte_horizontal for all firms? Our sample is at cycle-firm-candidate level, which is why I ask question whether cmte_sector_juris is firm/industry specific? Or if a candidate only sits on one horizontal committee has a oversight power over one particular industry, we tick both cmte_sector_juris and cmte_horizontal for that row? I think it's crucial to be specific about what LLMs should do in this situtation will make the result much more likely reproducible. 2. I agree with your suggestions that is "credit when the instrument reaches a substantial named segment, and require the segment to be named in a new field".

--- AGENT [2026-08-12 23:10:38] ----------
You've found the exact place where the design could go wrong, and the answer is better than you'd expect: **the LLM never faces this situation.**

The row-level logic is code, not judgment

The split is:

- **The LLM judges the grid** -- 69 industries x committees, each cell in isolation, output `reach ? {0, 1, 2}`. It never knows which candidates sit on which committees. It never sees a donation row.
- **Step 4 derives the row variables mechanically** -- take the candidate's `cmte_l1`, look each committee up in the grid against that firm's `hist_gics6`, apply a stated rule.

So there is no LLM ambiguity to guard against here. That's precisely why this architecture is reproducible: the judgment happens once per industry-committee cell and is reused, rather than being re-litigated 1,000 times at row level.

The two variables are different objects -- give them different names

Your instinct that "horizontal" might be industry-specific is right, and the resolution is that there are **two** variables, not one:

variable	level	firm-specific?	derivation
`cand_horiz_cmte`	candidate	**no**	sits on any of the six horizontal committees
`cmte_horiz_reach`	firm x candidate	**yes**	a committee they sit on has `reach == 1` for this firm's gics6

The first is a candidate characteristic -- it belongs in the covariate block and must not vary by firm, or it stops absorbing generic access value. The second is the interesting one: "this candidate reaches this firm, but only through a general instrument." That's the contrast category your analysis actually wants.

Your worked case

Take a candidate who sits on Judiciary and nothing else:

firm's industry	grid `reach`	`cmte_sector_juris`	`cmte_horiz_reach`	`cand_horiz_cmte`
Pharmaceuticals	**2** -- Hatch-Waxman, CSA/DEA	**1**	0	1
Electric Utilities	**1** -- antitrust, bankruptcy only	0	**1**	1

So **no, you don't tick both** for pharma. Judiciary is acting *sectorally* there, so it fires `cmte_sector_juris` and not `cmte_horiz_reach`. For the utility the same committee fires only the horizontal variable. `cand_horiz_cmte` is 1 in both rows because it describes the candidate, not the match.

This is the real payoff of the three-way code. It isn't documentation -- it's what makes the two variables mutually exclusive and well-defined at cell level. With a binary you couldn't distinguish "judiciary reaches utilities generically" from "judiciary doesn't reach utilities," and `cmte_horiz_reach` would be uncomputable.

Aggregation across multiple committees

Most candidates sit on several, so the rule needs stating. I'd make it a single ordered categorical rather than two dummies:

```
cmte_tier = "sectoral"        if ANY committee in cmte_l1 has reach == 2 for this gics6
          = "horizontal_only" else if ANY has reach == 1
          = "none"            otherwise
```

```
cmte_sector_juris = (cmte_tier == "sectoral")
```

Sectoral dominates: a candidate on both E&C (sectoral for pharma) and Judiciary (also sectoral for pharma) is simply `sectoral`. One on Judiciary alone facing a utility is `horizontal_only`. One on Agriculture facing a software firm is `none`.

That gives you a clean three-way contrast for the gate -- does sectoral jurisdiction attract donations relative to horizontal-only, and horizontal-only relative to none? -- with `none` as the omitted category. Much sharper than a binary, and it uses the extra coding you're paying for anyway.

Where it gets written down

Two places, and neither is the subagent prompt:

- **RUNBOOK step 4** -- the join. Its current text says "set `cmte_sector_juris = 1` if ANY surviving committee has `has_jurisdiction = 1`," which needs replacing with the tier rule above.
- **`classification_prompt_v3.md` ?5 and `run_procedure.md` ?2** -- the schema and derivations.

The 2c subagent prompt says nothing about any of this. It asks one question per cell: does this committee reach this industry, and if so, through a sectoral or a horizontal instrument.

So the 2c schema is settled: `reach` (2/1/0), `instrument`, `segment`, `note`, with `has_jurisdiction` and `cmte_tier` derived downstream. Six committees, 168 cells, agriculture/financial-services addendum separate.

Ready to write the worklist and prompt when you are.

--- AUTHOR [2026-08-12 23:17:57] ----------
1. This is great example " Take a candidate who sits on Judiciary and nothing else:

firm's industry	grid reach	cmte_sector_juris	cmte_horiz_reach	cand_horiz_cmte
Pharmaceuticals	2 -- Hatch-Waxman, CSA/DEA	1	0	1
Electric Utilities	1 -- antitrust, bankruptcy only	0	1	1

" and the three-way contrast you talked about in the last run. We should keep it in a note for maunscript writing in \2026.07 AI - Political Donation Motive\Manuscript. 2. I want to confirm what reach == 0, 1, and 2 means? 3. What files will we need to update the make the flow work?

Empty. Writing the design note there.
[action] Write: G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI - Political Donation Motive\Manuscript\NOTE_committee_measure_design.

--- AGENT [2026-08-12 23:19:38] ----------
Note written to `Manuscript/NOTE_committee_measure_design.md`.

2. What `reach` means

`reach`	definition	`instrument` field
2	The committee reaches this industry through a **sectoral instrument** -- a statute, programme or regulatory regime whose scope is defined by what this industry makes, sells or operates.	**required**, named specifically

| **1** | The committee **does** reach this industry with identifiable force, but the instrument is **horizontal** -- defined by a legal function that applies to firms in every sector, with only intensity varying. | **required**, named specifically |
| **0** | No exposure beyond what every firm in the economy faces. | **empty** |

The 1 / 0 line is the one that needs care, and the `instrument` field enforces it. A committee like Judiciary technically touches every industry through antitrust, so "reaches" can't mean "any conceivable contact" or `reach = 1` becomes universal and useless. The operative test is whether you can **name an instrument and show it bites this industry particularly**:

- Chemicals x Education & Workforce -> **1**. OSHA's process-safety-management standard is written *about* chemical processes.
- Software x Education & Workforce -> **0**. Ordinary employment law, nothing nameable.

Both 1 and 2 require the instrument on the record; 0 requires nothing. That's what makes the distinction auditable later -- the same property that let me classify 361 v2 credits this afternoon.

Tie-break: if a committee has both a sectoral and a horizontal instrument for an industry, `reach = 2`. Highest reach wins, and the sectoral instrument is the one named.

3. Files to update

New, for 2c to run:

file	contents
`Data/20260812/grid_v2/` + `committee_industry_grid_v2.csv`	backup of the current live grid before anything overwrites it
`Data/20260812/rejudge2_worklist.csv`	168 cells across 6 committees (+13-cell addendum, flagged separately)
`Guidance/grid_rejudge2_prompt.md`	researcher-facing protocol, same shape as `grid_rejudge_prompt.md`
`Guidance/grid_rejudge2_subagent_template.md`	the exact per-industry prompt, recorded for reproducibility

Edited, for the standard and schema:

file	what changes
`Guidance/taxonomy_decisions.md`	the sectoral/horizontal standard; the `reach` 0/1/2 scheme; the segment rule; the decision to demote W&M/Appropriations out of the motive set, with reasoning
`Guidance/classification_prompt_v3.md`	?4 `cmte_sector_juris` definition rewritten around the standard; ?5 output schema -- `committee = cmte_sector_juris` only; the within-industry segment rule
`Guidance/run_procedure.md` ?2	derivations: `cmte_tier`, `cand_horiz_cmte`, `cmte_wm`, `cmte_approp`; remove the `max()` union
`Guidance/RUNBOOK.md`	insert step 2c; rewrite step 4's join rule for the three-way code and the tier; note that step 3 now waits on 2c
`Guidance/_runlog.md`	entry when 2c completes

Grid schema change, and one thing to decide:

The grid gains `reach` and `segment`. I'd **keep the existing `strand` column name** rather than renaming to `instrument` -- it already means "the specific jurisdiction," and renaming churns v1/v2 for no analytical gain. `has_jurisdiction` stops being judged and becomes derived as `(reach == 2)`.

Backfill, with a disclosure. The ~1,143 cells not re-judged need a `reach` value: `2` where `has_jurisdiction == 1`, `0` where `has_jurisdiction == 0`. That last assignment is not strictly true -- some of those zeros are really horizontal reach -- so the runlog and the note should state that **`reach = 1` is coded only where a prior pass credited the cell.** Analytically it costs nothing, since 1 and 0 both give `cmte_sector_juris = 0`, but it matters for how `cmte_tier`'s `horizontal_only` category is read: it under-counts.

If you'd rather not carry that asymmetry, the alternative is re-judging all 1,311 cells three-way. Roughly eight times the cost of 2c, and it would re-open cells that already passed a strict test. I'd take the disclosure.

Ready to build. Order: backup v2 -> worklist -> prompt -> dispatch. The Guidance edits can happen while 2c runs, since the subagent prompt doesn't reference them.

```
--- AUTHOR  [2026-08-12 23:22:34] ----------------------------------------
I think it would be better to judge all 1,311 cells three-way because it gives consistence. Before doing it,
I want to make sure all affected files and prompts are updated accordingly. You can start updadting those
files.

All files are updated. Nothing has been re-judged yet -- the grid on disk is still v2.

## What changed
```

New files

file	what it is
`Manuscript/NOTE_committee_measure_design.md`	the design note -- standard, three-way code, the Judiciary worked example, the three-way contrast, validation logic
`Guidance/grid_v3_build_prompt.md`	researcher-facing protocol for the full 1,311-cell rebuild
`Guidance/grid_v3_subagent_template.md`	the exact per-industry prompt, `<CODE>`/`<NAME>` the only substitutions

Backed up before anything can overwrite

`Data/20260812/grid_v2/` (69 per-industry files, reconstructed from the assembled v2) and `committee_industry_grid_v2.csv`. v1 was already preserved. `committee_industry_grid.csv` is still v2 and stays that way until the rebuild assembles.

Edited

- **`run_procedure.md` ?2** -- `n_motives` drops to four; `committee = cmte_sector_juris`; new section deriving `cmte_tier` from the grid; new section putting `cmte_wm`, `cmte_approp`, `cand_horiz_cmte` in the covariate block with the firm-invariance argument. ?4 gains the sharper redundancy gate, including the candidate x cycle FE specification.
- **`RUNBOOK.md`** -- step 2b marked done and superseded; **step 2c added** pointing at the new prompt; step 4's join rule rewritten for `reach` and `cmte_tier`, plus the three firm-invariant controls; session table and forbidden-actions table updated; a line stating grid version numbers are independent of taxonomy version numbers.
- **`classification_prompt_v3.md`** -- `cmte_sector_juris` is now marked supplied-from-grid rather than judged per row, with the standard stated inline; motive fields cut from five to four; new subsection on firm-invariant controls; `motive_detail` and `confidence` rescoped to `social_tie` and `other`; do-not-edit list extended.
- **`taxonomy_decisions.md`** -- full decision record: the standard, the three-way code, the segment rule, why W&M and Appropriations left the motive set, the cell-not-committee point with the worked table, what was rejected and why, and the horizontal-share evidence that triggered it.

Two things worth flagging

The prompt no longer asks the model for `cmte_sector_juris` at row level. That's a real change in what step 5 does -- it now fills only `social_tie` and `other`. If you'd rather keep the row-level pass as an independent check on the grid join, say so and I'll restore it as a separate validation field rather than the production one.

Budget. You were at $19.47 / $20.00 before this turn. The rebuild is 69 subagents -- roughly 40% more than 2b's dispatch, since every agent judges 19 cells rather than 1-5. It will not fit in what's left. Worth sorting the account before starting, so it doesn't die at industry 20 and leave a half-built grid.

When you're ready: fresh session, paste `Follow Guidance/grid_v3_build_prompt.md`.

--- AUTHOR [2026-08-12 23:56:40] --
Before I running it, I want to confirm whether you think this is the best solution/approach for the project. Do we also need to change other things? Since I don't want to redo things

Before I running it, I want to confirm whether you think this is the best solution/approach for the project. Do we also need to change other things? Since I think it will take more time to redo things if something looks wrong at this stage

--- AGENT   [2026-08-12 23:58:34] --
Direction is right. **Sequencing is wrong, and there are three things I'd fix before you spend the money.**

The thing I'd change: run step 4 before the rebuild

Your own gate protocol says the first question is whether the LLM label carries information beyond home-district match, committee assignment, party and incumbency -- "if it does not, the measure is a nonlinear re-expression of the covariates and the paper has no engine."

That gate has never been run on `cmte_sector_juris`. The 40.5% figure in the runlog is from the taxonomy-v1 pilot, a different measure with a different definition. We have spent a day refining a variable whose central diagnostic is unmeasured.

Step 4 is pure code, costs almost nothing, and answers three things the rebuild decision depends on:

- the row-level `cmte_sector_juris` rate under v2
- whether it survives the redundancy gate
- the 27% E&C-only share that motivated 2b in the first place -- still uncomputed

If v2 already fails the gate, v3 won't save it and you'd want to know that before spending. If it passes with room, you learn how much the tightening can afford to cut. Either way the join is reversible -- rebuild the grid and rejoin.

A pattern worth naming

This is grid pass three in one day, and each was triggered by a diagnostic run *after* the pass. That's a good feedback loop, but it has no stopping rule. **Before running v3, write down what result would count as success.** Otherwise pass four gets triggered the same way.

Concretely, state now: judiciary should land near 10-25 of 69; foreign affairs near 3-8; the four procedural committees at 0; overall `reach == 2` share somewhere near 15-20% against v2's 27.5%. If judiciary comes back at 40, that's a fail and you'll know it without re-litigating. If it comes back at 5, the standard over-cut.

I can add these to `grid_v3_build_prompt.md` as an ex-ante prediction block, which is exactly what `gate-design` asks for.

Three things to fix before running

1. Cycle-varying jurisdiction is unhandled, and v3 will inherit it. Three agents flagged independently that E&C's securities and insurance jurisdiction moved to Financial Services in January 2001 -- so cycle 2000 is genuinely different for Banks, Capital Markets, Diversified Financials and Insurance. Homeland Security did not exist as a standing committee until 2005, so it cannot be in `cmte_l1` for cycles 2000, 2002 and part of 2004 -- yet it now has 29 credited cells.

The grid is one time-invariant object. Cheapest correct fix, in step 4 rather than the grid: drop homeland security cells for pre-2005 cycles, and flag the four financial industries' E&C cells for cycle 2000. Two lines of code, and it removes a defect a referee would find.

2. `other` has the same defect `cmte_sector_juris` had in v1. It's defined as "a specific, nameable reason" -- a concept with no decision rule -- which is precisely what produced the inconsistency you've spent today fixing. Step 5 will reproduce it. Since the prompt is already open, worth giving `other` a test rather than a definition.

3. `social_tie` fires on ~0.6% of rows -- 6 rows in 1,000. That will not support anything on the trial sample. Fine on the full 520k master, decorative here. Worth knowing before step 5 costs a session.

One decision you should make consciously, not by drift

Your CLAUDE.md describes the project as using an LLM "to read a firm-politician-cycle record and infer the primary motive."

After this change, the LLM reads no donation record for the committee motive. `geography` is mechanical, `cmte_wm_approp` is mechanical, and `cmte_sector_juris` is now a lookup against a crosswalk the LLM built once. Per-row LLM inference is `social_tie` and `other` -- together under 1% of rows.

That may well be the right paper. "The LLM's value is a reusable, auditable jurisdiction crosswalk, not per-row inference" is honest, defensible, and scales to 520,011 rows in a way per-row classification never would. But it is a **different contribution** from the one currently written down, and the RAP should say so before the AFA abstract does.

What I'd do, in order

1. **Step 4 join on v2** -- nearly free, and it's the gate. *(today)*
2. **Read the result.** If the gate passes, proceed. If it fails badly, the problem is not the grid's calibration and v3 won't fix it.
3. **Add the ex-ante prediction block and the cycle-validity rule**, then run v3.
4. Step 3 reproducibility, fresh session.
5. KSW validation build, firewalled.

The only cost of this ordering is that step 4 runs twice. It's code; it's minutes.

Want me to run step 4 against v2 now? It fits in the budget you have left, and it's the piece of information most likely to change what you do next.

```
--- AUTHOR  [2026-08-13 00:04:10] ----------------------------------------
1. "The LLM's value is a reusable, auditable jurisdiction crosswalk, not per-row inference" is correct
understanding of what we want to do, especially when we care about whether the results are reproducible. You
can update project md to reflect this. It's ok to have LLMs to have inference, but if we don't really need
such inferences due to existence of other better solutions, it's good to not make inferences. 2. All steps
should serve the project goals and are open to be updated. Given this, I actually think it may be a good move
to start grid_v3_build_prompt. What do you think? Do we need to update anything in
Guidance/grid_v3_build_prompt.md?

--- AGENT   [2026-08-13 00:04:54] ----------------------------------------
Good -- and on sequencing you've changed my mind. Running the gate on v2 measures a grid we've already
declared internally inconsistent, so a pass or a fail is hard to attribute. Start v3.

But one number is worth two minutes first, and it isn't the gate -- it's **power**. If v2 fires on few rows
already, v3's tightening could leave too little variation to estimate anything.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python -c " import pandas as pd,

--- AGENT   [2026-08-13 00:05:34] ----------------------------------------
That number changes the picture, and it argues for v3 more strongly than anything so far.
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -

      ↪  Political Donation Motive" && python -c " import pandas as pd,

--- AGENT   [2026-08-13 00:06:45] ----------------------------------------
That's the number that matters. Grounded prediction, from simulating the v3 cut on v2:

| | grid density | row-level rate |
|---|---|---|
| v2 actual | 27.5% (361 cells) | **51.8%** |
| v3 simulated | 16.6% (217 cells) | **44.0%** |

**v3 fixes the grid but only partly fixes the row-level measure.** Density falls by 40%; the row rate falls
by 8 points. The reason is that E&C (45/69) and T&I (39/69) survive the standard legitimately *and* are among
the most commonly held committees -- so most candidates still hit something. 44% of rows, and 62% of
committee-holders, still fire.

That doesn't argue against v3. It argues that v3 is necessary but not sufficient, and you should know that
before you spend rather than after. Updating the prompt with this as the stated prediction.

--- AGENT   [2026-08-13 00:08:10] ----------------------------------------
Everything is ready. My honest assessment:

## Yes, start v3 -- and your reasoning is better than mine was

Once the crosswalk *is* the contribution, its internal consistency is the deliverable regardless of what the
redundancy gate later says. Running the gate first on a grid you've already declared inconsistent produces a
number you can't attribute. You were right.

## What I added to the prompt
```

1. An ex-ante prediction block with failure conditions. This is the change that matters most, because it converts v3 from "another pass" into a test with a stopping rule. Derived by simulating the standard on v2, not guessed:

- grid density 27.5% -> predicted **15-18%**
- judiciary 49/69 -> predicted **5-20**; above 30 means the standard didn't bite, below 3 means it over-cut
- E&C and T&I should barely move -- if they shift more than ~10 cells, the standard is doing something other than what 2b did

2. Known jurisdictional changes, stated once. Homeland Security didn't exist before 2005; E&C's securities and insurance jurisdiction moved to Financial Services in January 2001. Giving these to all 69 agents beats having 29 of them derive it independently in different words. The grid stays time-invariant; cycle corrections happen at the join.

3. A disclosure about seeded cells. The template's worked contrasts name four specific industry-committee pairs -- machinery/Title II, pharma/Hatch-Waxman, mining/Mine Act, chemicals/CFATS. Those cells are effectively dictated and are not independent draws. Step 3's reproducibility check should report them separately if the random draw hits them.

The one thing I'd want you to carry into it

v3 fixes the grid; it does not fix the row-level measure. 51.8% -> 44.0%. E&C and T&I survive the standard on merit and are among the most commonly held committees, so most candidates still hit something. The remaining leverage is `cmte_tier`'s three-way contrast and candidate x cycle fixed effects -- and the trial sample averages 1.7 rows per candidate, so it cannot support the candidate-FE specification at all. That test needs the 520,011-row master.

Not a reason to delay. A reason not to be surprised.

State

Ready: `grid_v3_build_prompt.md`, `grid_v3_subagent_template.md`, `Data/20260812/grid_v3/`, v1 and v2 both preserved, `CLAUDE.md` reframed, `taxonomy_decisions.md`, `run_procedure.md`, `RUNBOOK.md` and `classification_prompt_v3.md` all updated.

Queued, not blocking: the `other` definition still needs a test rather than a concept -- same defect v1's `cmte_sector_juris` had -- but that bites at step 5, not now.

Budget: you have ~$0.53. Sixty-nine agents each judging 19 cells is materially more than 2b's dispatch. Sort the account before starting, or it dies partway and you resume into a half-built grid -- recoverable, since per-industry files persist, but wasteful.

Fresh session, then paste: `Follow Guidance/grid_v3_build_prompt.md`

--- AUTHOR [2026-08-13 00:09:07] ----------
In a way, it's difficult to say which classification is most correct. The project is to understand the motive of firms' political donation motives, so a general picture is way more important than a precise picture because people have different precise pictures.

--- AGENT [2026-08-13 00:09:36] ----------
Agreed on the substance, with one distinction that I think matters for what you do next.

You're right that there's no ground truth here. "Does Judiciary have jurisdiction over utilities" has no fact of the matter -- it's a construct, and reasonable coders land differently. The v1->v2 diff proved it: 19 E&C cells flipped without a single new fact entering, purely on a convention change. Chasing cell-level correctness is chasing something that doesn't exist.

But imprecision and inconsistency behave differently, and only one of them averages out.

If cells are noisy around a consistently applied standard, the general picture survives -- errors are roughly orthogonal to what you're measuring. That's the case where your instinct is exactly right and further refinement buys nothing.

E&C at 93% wasn't that. It wasn't noise around the target; it was the measure converging on a *different variable* -- "does this candidate hold a committee seat." That bias is correlated with the treatment, so it doesn't w

In a way, it's difficult to say which classification is the most correct. The project is to understand firms'
political donation motives, so a general picture is way more important than a precise picture because people
have different precise pictures. And yes, inconsistency is more important than imprecision.

--- AGENT   [2026-08-13 00:10:52] ----------------------------------------
Then the project has a stopping rule it didn't have this morning: **stop when the standard is one thing, not
when the cells feel right.** v3 is the last grid pass unless a *consistency* defect turns up -- not a cell
you'd have coded differently. That closes the loop that produced three passes in a day.

Three things follow that are worth building in now.

**Convention-sensitivity becomes a headline number, not an appendix caveat.** Since no ground truth exists,
the honest statistic is how much the picture moves under a defensible alternative coding. You already have
v1<->v2, and you'll have v2<->v3. Most papers with hand-built industry classifications report nothing of the
kind -- they present one crosswalk and assert it. Reporting "here is the motive distribution, and here is how
much it moves under a reasonable alternative convention" is a stronger claim than a single number, precisely
because it concedes the thing your instinct is right about.

**So report the motive distribution under more than one grid.** The join is code, so running it under v2 and
v3 costs minutes. If the ordering of motives is stable across both, that *is* the general picture and it's
robust. If the ordering flips, that's a finding you need to know before a referee finds it.

**One caution, because it's the place where the general picture can still mislead.** If `cmte_sector_juris`
fires on 44% of rows and `geography` on 11%, the natural reading is "committee jurisdiction dominates." But
that gap is partly an artifact of one measure being broad and the other narrow. The general picture is only
interpretable once the redundancy gate says the committee measure carries information beyond "holds a
committee seat." That's not precision in the cell-level sense you're setting aside -- it's whether the
variable is the variable you think it is.

The three-way code helps here too: `reach = 1` cells are exactly the contested zone, so a reader can see
where the boundary sits instead of trusting it.

--- AUTHOR  [2026-08-13 00:12:52] ----------------------------------------
So actually it will help if we have "The LLM's value is a reusable, auditable jurisdiction crosswalk, not
per-row inference" and make LLMs do more matching and checking works rather than inference works. I think
this "If cmte_sector_juris fires on 44% of rows and geography on 11%, the natural reading is "committee
jurisdiction dominates." But that gap is partly an artifact of one measure being broad and the other narrow."
is OK. Given this, will Guidance/grid_v3_build_prompt.md be read to run?

--- AUTHOR  [2026-08-13 00:13:05] ----------------------------------------

--- AGENT   [2026-08-13 00:13:53] ----------------------------------------
Structure is sound -- fence runs 38-175, everything the session needs is inside it. Two small guards to add
before it's safe to run.
      [action] Edit: G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI -
      ↪  Political Donation Motive\Guidance\grid_v3_build_prompt.md
      [action] Edit: G:\OneDrive - The Pennsylvania State University\PhD research projects\2026.07 AI -
      ↪  Political Donation Motive\Guidance\grid_v3_build_prompt.md

--- AGENT   [2026-08-13 00:14:14] ----------------------------------------
**Yes -- it's ready to run.**
```

Verified just now:

fence structure	one block, lines 38-179; everything the session needs is inside it
subagent template	one block, `<CODE>` / `<NAME>` the only substitutions
`grid_industries.csv`	69 rows, codes and names
`Data/20260812/grid_v3/`	created and empty
v1 preserved	`grid_v1/` + `committee_industry_grid_v1.csv`
v2 preserved	`grid_v2/` + `committee_industry_grid_v2.csv`
live grid	still v2, untouched until v3 assembles

The two guards I just added were the last real gaps. The first matters most: the orchestrator now sees the ex-ante prediction, and without an explicit rule it might re-run industries whose numbers look off -- which would be tuning to a target and would silently destroy the reproducibility statistic. It's now stated that a file which parses is final. The second just removes an ambiguity about whether the orchestrator needs to inject the jurisdictional facts (it doesn't; they're in the template).

To run: fresh session, paste exactly

```
Follow Guidance/grid_v3_build_prompt.md.
```

Fresh matters more than usual this time. I've seen v1 and v2 in this session, and while the subagents are blind regardless, the orchestrator reads the assembled result and reports against the prediction -- that report is cleaner from a context with no stake in the answer.

Two things to expect. It's 69 agents at 19 cells each, so materially more than 2b -- sort the account first. And the run will produce a `reach = 1` layer that has never existed before, so the first assembly report is the one to read carefully: `reach = 1` counts per committee are the new object, and they're where the contested boundary now lives.

--- AUTHOR [2026-08-13 02:47:37] ----------
I've rerun grid_v3_build_prompt. Are the outputs what we expect? What should I do the next? I feel I actually don't fully understand v3. I understand this is the defintion of the reach definition:

reach	definition	instrument field
2	The committee reaches this industry through a sectoral instrument -- a statute, programme or regulatory regime whose scope is defined by what this industry makes, sells or operates.	required, named specifically
1	The committee does reach this industry with identifiable force, but the instrument is -- defined by a legal function that applies to firms in every sector, with only intensity varying.	horizontal | required, named specifically
0	No exposure beyond what every firm in the economy faces.	empty

Does it mainly change the how an industry relates to one committee? How will the different linkage way affect our polticial motive
column classification? Can you help me understand what we want to do with grid v3 and how it will affect

```
v3 classification?

--- AGENT   [2026-08-13 02:48:00] ----------------------------------------

      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive/Data/20260812" && python -c " import
      [action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI -
      ↪  Political Donation Motive" && python -c " import pandas as pd,

--- AGENT   [2026-08-13 02:50:31] ----------------------------------------
I checked it against the prediction we wrote before the run. **It failed on the headline quantity**, and the
diagnosis is instructive.

## Against the pre-registered prediction

| quantity | predicted | actual | |
|---|---|---|---|
| cells at `reach = 2` | 190-240 (15-18%) | **367 (28.0%)** | ? no reduction at all (v2 was 361) |
| row-level `cmte_sector_juris` | 40-47% | **52.8%** | ? went up (v2 gave 51.8%) |
| **energy and commerce** | 35-48 | **64** | ?? back to v1's level |
| judiciary | 5-20 | 29 | ? above range, but moved 49->29 |
| foreign affairs | 1-8 | 9 | ~ just outside |
| oversight / homeland / science / educ&workforce | 3-12 each | 14 / 21 / 21 / 19 | ? above |
| transportation and infrastructure | 32-42 | 43 | ? |
| budget / rules / ethics | 0 | 0 / 0 / 0 | ? |
| house administration | 0 | **2** | flagged -- see below |

**What went right:** every horizontal-heavy committee moved in the right direction, and the `reach = 1` layer
is real -- 279 cells, 21% of the grid. That's genuinely new information the binary could never hold.

**What went wrong:** E&C went 45 -> 64, taking back all 19 cells that 2b had cut, and cancelling every other
gain.

## The diagnosis -- and it's a flaw in the prompt I wrote

**The sectoral/horizontal test and the principal-authority test are different tests, and they are not
nested.**

Judiciary *fails* the sectoral test, because antitrust and bankruptcy are function-scoped. So the new
standard bit there, as designed.

E&C *passes* the sectoral test easily, because its instruments are product-scoped. Look at the cells that
came back: Clean Air Act ?213 marine diesel standards are literally "defined by what marine transportation
operates." CPSC/CPSIA rules are "defined by what specialty retail sells." Semiconductor NESHAP names the
industry. Every one satisfies the standard as written -- the agents applied it correctly.

What cut E&C in 2b was a **different question**: is this among the two or three committees that most shape
the business? An airline's operating law is FAA and T&I; aircraft-engine emissions are real but secondary.
That is a *primacy* test, not a *scope* test.

By generalising to the scope test and dropping the primacy test, I removed the only thing disciplining E&C.
That's my error in `grid_v3_subagent_template.md`, not the agents' work.

On **house administration = 2**: those are GPO contract printing for Commercial Services, and FECA/BCRA
political-advertising rules for Media. Political-ad rules genuinely do reach broadcasters specifically. The
protocol asked for exceptions to be recorded rather than assumed away, and they were. I'd keep them visible
rather than treat them as errors.

## What v3 actually does -- your conceptual question

**`reach` changes exactly one thing in the final data:** whether a committee "counts" for a given firm.

For each donation row, the candidate's sitting committees are looked up against that firm's industry:
```

```
- any committee at `reach = 2` -> `cmte_sector_juris = 1`
- else any at `reach = 1` -> `cmte_tier = horizontal_only`, and `cmte_sector_juris = 0`
- else -> `none`

On your 1,000 rows under v3: **52.8% sectoral, 9.3% horizontal_only, 37.9% none.**

So the only job of `reach = 1` is to split the old "0" into two things -- *"this candidate's committees don't
touch this firm at all"* versus *"they touch it, but only the way they touch everyone."* That's the middle
category the binary couldn't express.

**How it affects the motive classification:** `cmte_sector_juris` is one of four motive flags. At 52.8% it
fires on more than half of all rows -- nearly five times `geography` at 11.3%. So the motive distribution you
report will be dominated by committee. And the worry from earlier is now concrete rather than hypothetical:
that dominance is partly an artifact of the measure being broad, and E&C alone accounts for most of it.

## What I'd do next

Three options.

**(a) Accept v3 and disclose.** Defensible -- one standard, consistently applied, fully documented. Cost: the
committee motive fires on 53% of rows, and the redundancy gate will probably be unkind.

**(b) Add the missing prong -- re-judge only the 367 `reach = 2` cells under the primacy test.** Cells that
fail drop to `reach = 1`. This applies to *every* committee equally, so it doesn't reintroduce
committee-specific standards; it completes a standard that was under-specified. About 5 cells per industry,
so materially cheaper than v3 was.

**(c) Revert E&C to v2's 45 and keep v3 elsewhere.** Cheapest, but it's exactly the committee-specific
patching you decided against.

**I'd take (b)** -- and I want to be explicit about why this isn't just another pass. This one is diagnosed
against a prediction written in advance that failed, with a named cause: the standard had two prongs and I
wrote one. That's a different situation from the earlier passes, which were triggered by post-hoc diagnostics
with no stated target.

If you'd rather stop, (a) is honest and the paper survives it -- but then the redundancy gate becomes the
decisive test rather than a formality, and you should run step 4 before committing to anything downstream.

1. How many motives would we plan to have in v3? Do we need to revise the taxonomy? 2. Why do you think we
may need to do (b)?

--- AGENT   [2026-08-13 02:55:11] ----------------------------------------
Two honest answers, and the second is a correction to what I told you last turn.

## 1. Motives in v3 -- four, and I would not change the count

But the shape is lopsided and that matters more than the number:

| motive | rate | |
|---|---|---|
| `cmte_sector_juris` | 52.8% | supplied from grid |
| `geography` | 11.3% | supplied, mechanical |
| `social_tie` | ~0.6% | model-judged |
| `other` | ~0.1% | model-judged |

Two carry essentially all the mass; two are near-empty. On 1,000 rows that's 6 and 1 observations --
decorative here, workable only on the 520,011-row master.

**I'd keep all four.** `social_tie` at under 1% is not a failed category, it's a **result** -- the literature
talks a great deal about personal connections, and finding almost none under a documented +/-5-year
same-institution test is worth reporting. Deleting it would suppress a finding.

Three things I would change about how the taxonomy is *used*, none of which requires re-judging anything:

**Make `cmte_tier` the headline committee variable, not the binary.** You paid for the three-way code; the
```

binary throws away the middle. The joint table is the real object:

	geography = 0	geography = 1	total
sectoral	480	48	**528**
horizontal_only	75	18	**93**
none	332	47	**379**

The headline number may be the bottom-left cell: 33.2% of donations have no committee reach and no geographic connection. A third of corporate PAC giving, with nothing in the record tying the firm to the candidate. That speaks directly to your research question, and it comes free.

Fix the reporting object. v1 and v2 were priority-ranked, so "the distribution of motives" was well defined. v3 made them non-exclusive checkboxes, which is more honest per-row but means you can no longer say "X% are geography-motivated" -- a row can be both. Report the joint distribution, as above, not a ranked list. That should go into `taxonomy_decisions.md`.

No revision to the taxonomy itself is needed. The v3 edits already did the substantive work: four motives, W&M and Appropriations demoted to covariates, `cmte_tier` added.

2. Why (b) -- weaker than I made it sound

Fair challenge, and on reflection **my recommendation was premature.** Here's the honest accounting.

The case against (b), which I under-weighted:

The primacy test -- "would a general counsel name this committee in the top three?" -- has no documentary anchor. The scope test does: you can check a statute's coverage language and see whether it names the industry. Primacy is a judgment about salience, and we have direct evidence it produces disagreement -- 2b's agents and v3's agents split on the same E&C cells using tests of the two kinds.

So (b) would buy a lower hit rate at the cost of **making the grid less reproducible** -- which is now the paper's central claim. That's a bad trade to make reflexively.

The case for (b): at 52.8%, `cmte_sector_juris` fires for 74% of rows that hold any gradeable committee. It's drifting toward "does this candidate sit on a committee," which is the failure the project's own gate exists to catch.

But that's a hypothesis, and it's testable -- and we haven't tested it. The gate asks whether the label carries information beyond the mechanical indicators. 74% is high, not 100%, and whether the residual is informative is an empirical question, not something to infer from a rate.

So: run step 4 and the redundancy gate before deciding anything. It's code, it costs minutes, and it's now decision-relevant in a way it wasn't before -- earlier I was proposing it on a grid we'd already decided to replace; now v3 is the live grid and the gate speaks to it directly.

- If `cmte_sector_juris` clears the gate at 52.8%, **(b) is unnecessary** and would cost reproducibility for nothing.
- If it fails, we know a fix is needed *and* we have a target to aim at, instead of guessing at a rate that looks respectable.

I should have said that last turn instead of reaching for another pass. Shall I run step 4 now?

--- AUTHOR [2026-08-13 03:02:51] ----------
I remember we plan to not impose priority order in v3, so a donation can check both geography = 1 and cmte_donation. Given this, I'm thinking about whether we can make the classification result more informative in the first place by doing this: instead of having cmte_sector_juris, we can direcly make columns based on reach = 0, 1, 2 or just 1 and 2. I also feel the current cmte_sector_juris overlaps with reach = 1? Also, is the distinction among reach = 0, 1, 2 only applicable to horizontal cmte?

--- AGENT [2026-08-13 03:03:22] ----------
Three good questions, and one of them rests on a misunderstanding worth clearing up. Let me get the numbers first.

[action] Bash: cd "G:/OneDrive - The Pennsylvania State University/PhD research projects/2026.07 AI - Political Donation Motive" && python -c " import pandas as pd,

--- AGENT [2026-08-13 03:04:17] ----------
Is `reach` only for horizontal committees? No -- every cell got a code

This is the one to clear up first, because the rest follows from it. All 1,311 cells were coded 0/1/2,

including the most sectoral committees:

committee	reach 0	reach 1	reach 2
energy and commerce	1	4	64
transportation and infrastructure	16	10	43
agriculture	28	**8**	33
natural resources	37	10	22
judiciary	5	35	29
education and the workforce	10	40	19

Agriculture has 8 cells at reach 1 -- industries it reaches only through CFTC/derivatives, which is hedging law that touches every commodity user. Even T&I has 10.

Horizontal versus sectoral is a property of the instrument in that cell, not of the committee. That's why the standard is applied cell by cell and why "which committees are horizontal" was only ever a rough sorting device for deciding where to look.

Does `cmte_sector_juris` overlap with reach = 1? Not as coded -- but you've spotted a real loss

At row level they're mutually exclusive by construction: `cmte_tier` is `sectoral` if *any* committee is reach 2, and `horizontal_only` only if none is. So no double-counting.

But your instinct is right that something is being thrown away:

	no reach-1 cmte	has reach-1 cmte
no reach-2 cmte	379	93
has reach-2 cmte	395	**133**

133 rows (13.3%) hold both a sectoral and a horizontal committee, and `cmte_tier` codes every one of them as plain `sectoral`. The reach-1 information is discarded for exactly the rows where the candidate has the broadest reach into the firm. That's the overlap you're feeling -- not a coding collision, an information loss from collapsing a set of committees into one label.

So yes -- build columns from `reach` directly. Your proposal is better than what I specified

The clean form is to **store counts and derive everything else**, since counts lose nothing:

column	value on the 1,000 rows
`n_cmte_reach2`	0 -> 472, 1 -> 393, 2 -> 115, 3 -> 20
`n_cmte_reach1`	0 -> 774, 1 -> 191, 2 -> 33, 3 -> 1, 4 -> 1
`cmte_sector_juris` = `n_cmte_reach2 > 0`	**52.8%** (unchanged)
`cmte_horiz_reach` = `n_cmte_reach1 > 0`	**22.6%** (new -- and not exclusive with the above)
`cmte_tier`	keep, but as a derived collapse for descriptive tables, not the primary object

The counts also give you intensity for free: 135 rows hold two or three sectoral committees, which a dummy cannot express.

Should `cmte_horiz_reach` count as a motive? I'd report it but keep it out of `n_motives`. "A committee reaches your industry the way it reaches everyone" is a weak reason to prefer *this* candidate, and treating it as a motive would inflate the count. Its real value is as the **contrast group**: if `horizontal_only` rows attract donations at the same rate as `sectoral` rows, the committee channel is about access rather than jurisdiction -- and that is a genuine finding, one the binary could never have surfaced.

What this changes

Nothing needs re-judging. It's all derived at the join:

- `run_procedure.md` ?2 -- add the two counts, add `cmte_horiz_reach`, demote `cmte_tier` to derived
- `RUNBOOK.md` step 4 -- compute counts rather than the tier directly
- `taxonomy_decisions.md` -- record that the motive count stays at four and why `cmte_horiz_reach` is reported but not counted
